The Operative Treatment of Hypertrophied Prostate.—Dr. Bransford Lewis of St. Louis said that, while claiming for prostatic surgery the merit of wonderful progress in the last fifteen years, he thought that the profession was not above criticism in certain respects, and that operators were much inclined to follow beaten tracks and routine procedures rather than base their operative treatment on the especial conditions found in each individual case. He mentioned some points in the histories of some of his cases, which had a bearing on the subject. The first was one in which he himself had failed to cure; it was a case of prostatic retention, treated by means of the Bottini electro-incision. He then had desired to open suprapubically, but the patient objected. Later the patient consulted another surgeon and consented to the suprapubic operation, at which time an intravesical projection was removed, with the result of giving complete relief to the patient. The second case was one in which perineal prostatectomy had been done a year before by another surgeon, and yet no benefit accrued; the patient was compelled to depend on the catheter for evacuating his bladder for six months thereafter. In January of the present year Dr. Lewis made a suprapubic incision and removed an intravesical collar that surrounded the urethral opening and which had been causing the complete retention, notwithstanding that prostatectomy had been performed. A cure followed the second operation. The third case was that of a man sixty-five years old, very infirm, whose urine was albuminuric, and who had twenty-eight ounces of residual urine, and who urinated thirty-five times in twenty-four hours. Upon this patient he made one posterior incision with the Bottini-Freudenberg incisor, affording, practically, a prompt and complete relief from his various symptoms, with reduction of the residual urine from twenty-eight down to two ounces, and of the frequency from thirty-five to seven or eight times in twenty-four hours, with removal of the albuminuria and a rapid improvement in his general health. Later, the patient had been operated upon for inguinal hernia by another surgeon, became infected, suffered from erysipelas and gangrene of the lungs, intestines and of the wound, from which he died, permitting of the exhibition of the post-mortem specimen, which he presented. It showed the groove made by the cauterizer, through which free urination had been accomplished. The form of obstruction had been a prostatic bar. The fourth case mentioned was one of a gentleman who, four years ago, had been advised by a genitourinary surgeon to undergo some operation for hypertrophied prostate, but, on consulting the reader of this paper, was advised by him not to accept of any operation—he did not need any. Only antiseptic and dietary regimen had been prescribed for this case, and yet, during the past four years, he had had no indication of any trouble with his prostate or bladder. There had been no residual urine in the first place, and no reason for an operation had ever existed. The practical lessons to be derived from these cases were: That the proper selection of the operative procedure is of the greatest importance in attaining successful results; this was satisfactorily explained by the dozen or more specimens and models of hypertrophied prostates exhibited by the reader. In these the various forms of prostatic enlargement and obstruction were clear, including intravesical tumors and projections, the prostatic bar, the bilateral hypertrophy, sessile and pedunculated tumors, the nodular valves and the median outgrowths, adenomata, etc. From all of these it was plainly evident that no one operative procedure could possibly fit all cases, and that the operation should be selected according to the cases at hand, rather than the personal inclination of the operator. The condition favorable for the several operations in vogue were summed up as follows:

Favorable for the Suprapubic Route. (1) General enlargement of the prostate, with extreme intravesical projection of the median or lateral lobes, diminishing their accessibility from the perineum; (2) Marked pedunculation of the intravesical tumors, with absence of obstruction from other sources.

Favorable for the Perineal Route. (1) General hypertrophy, involving the lateral lobes, without extreme intravesical projection; (2) Large or very thick bar formation. (3) Severe compression of the urethra between massive lateral lobes; (4) Excessive development of the prostate in the direction of the rectum; (5) In most cases, where the patient is in good general condition, is not too aged, and there is not a special indication favoring one of the other procedures.

Favorable for the Bottini. (1) Cases of extreme debility or of extreme age, unable to stand one of the severer operations; (2) Cases of bar or median sessile obstruction, if not too great dimensions; (3) Horwitz says it should be employed as a prophylactic against further obstructive tendency, at the beginning of catheter life; (4) In complete collar formation.

Dr. F. L. Sturgis of New York said that the removal of the prostate and ejaculatory ducts prevented the flow of the prostatic secretion, which was so essential to the vitality of the spermatozoa, and, therefore, tended to render the male sterile. Some partial operation, such as the Bottini, was preferable on this account.

Dr. Eugene Fuller of New York did not think we could group the different forms of hypertrophied prostates under such a small class as shown by Dr. Lewis. If one had to deal with one hundred cases of prostatectomy, there would certainly be seventy-five of them that would represent something new. In cases complicated with troublesome hernias, many surgeons operated without having in mind the cause of the hernia, the straining, etc., consequent upon the urethral obstruction. No matter how severe the hernia seemed to be, if the bladder be opened and drainage instituted, the tenesmus ceases, and the patient may not again be troubled with the hernia. This also applied to prolapse of the rectum incident to the straining and tenesmus.

Dr. F. Tilden Brown of New York said that Dr. Lewis had failed to show how we were to know in advance just what form of prostatic enlargement we were to deal with. The use of the cystoscope, for this purpose, was very unsatisfactory. Again, it was very necessary that one should know the condition of the kidneys, and what sort of urinary obstruction we had to deal with, and this was difficult to learn. It seemed to him that where there was the slightest excuse for making a suprapubic incision for drainage such an incision should be made use of for the introduction of th cystoscope, with which one could look directly down and learn the nature of the obstruction [illegible] Recently he had the opportunity to [illegible] through a [illegible] opening in the [illegible] and he had [illegible] that [illegible] would have been impossible [illegible] of the cystoscope had been introduced through the urethra.

Dr. H. H. Young of Baltimore said that Dr. Lewis's results and [illegible] but that he had met with several kinds of prostatic obstruction which were not [illegible] One case [illegible] could be [illegible] cystoscope [illegible] to have a small globular tumor of the [illegible] which was causing the obstruction. He had had several cases of so-called small sclerotic prostate which showed by rectal and cystoscopic examination very little evidence of hypertrophy, and in which a prostatectomy would be impossible, that was cured by the Bottini operation. In four cases which had previously been castrated he found with the cystoscope a collarette of mucous membrane and fibrous tissue around the prostatic orifice which continued to cause obstruction after the lateral lobes had atrophied. This also was relieved by the very small blade of the electro-incisor. He wished to reassert his adherence to the radical removal by prostatectomy in fit subjects. He had used both the perineal and suprapubic routes, with but one death in fourteen cases. Many of his cases were so old that he feared the radical operation and general anæsthesia, and found the Bottini operation eminently satisfactory. He had had nineteen cases over seventy years of age, three over eighty, and operated under cocaine with the electro-cautery without a death, and with good results.

Dr. Sturgis of New York said that in the case of the tumor of the veru montanum the endoscope would have shown what the cystoscope had failed to show.

Dr. Bryson of St. Louis said he had had three or four such cases where he did an epicystotomy, and found a tuberculous condition; they were scraped, and cure followed.

Dr. William T. Belfield of Chicago said that none had as yet penetrated beyond the threshold in our endeavors to relieve these obstructions. It must be admitted that nothing was known regarding the etiology of these conditions. We all knew that some of the most violent cases of so-called prostatic obstruction occurs when there is no prostate at all. We know of certain young men whose prostates are not enlarged, nevertheless they have symptoms of prostatism with residual urine, etc. Such cases have been described by Chetwood and others under the name of contracture of the vesical neck. There are cases occurring in women with all the symptoms of prostatism, with complete retention, residual urine, trabeculated bladder, showing the efforts of the bladder to overcome the obstruction, and yet there is no prostate. He thought we were overestimating the importance of enlargement of the prostate as a cause of the trouble. He thought more attention should be paid to contractures, or fibrous degeneration of the vesical outlet, or what not, that may be present without any prostatic enlargement whatever. Again, we know that the prostate has no function except that imposed upon it by the internal secretion of the testicle; if we remove the testicle, the glandular part disappears by atrophy. If such is the case, and it be shown that the secretion of the testicle has anything to do with the production of the adenomatous enlargement, then it would seem rational to assume that no operation except a radical one would be of great benefit. The Bottini operation as a prophylactic one is unreliable. In the Bottini operation simply scratching offers no improvement which cannot soon be overcome by some causative agent which may be circulating in the blood.

Detection of Stone in the Kidney by Skiagraph. Dr. James Bell of Montreal exhibited photographs of [illegible] in which the skiagraph had demonstrated a stone with [illegible] satisfaction. The patient was rather a slight [illegible] She had first been attack of colic when she was four months pregnant in 1897. [illegible] three months pregnant she had another attack. [illegible] she had other attacks occurring on the right side. [illegible] but [illegible] that she had [illegible] swelling on that side [illegible] After admission to the hospital skiagraphs were taken which showed a small [illegible] in the lower half of the kidney, which was removed by the [illegible] and it was shown to have the [illegible]

SECOND DAY, APRIL [illegible], 1902

The morning session was devoted to a General Discussion of the Surgical Treatment of Genito-urinary Tuberculosis.

Renal Tuberculosis. Dr. F. Tilden Brown of New York opened the general discussion on this topic and said that the results of necropsies were at variance with the clinical showings in the disease as a rule, and that if we relied upon the evidence as produced at autopsies we would be convinced that there were but few cases of isolated renal tuberculosis which justified surgical intervention. He thought that a contribution from the hospital records extending over a period of ten years would be of value, although the statistics were incomplete. At the Presbyterian Hospital, New York, from February, 1892, to March, 1902, there were 1,427 necropsies, of which number 258 (18 per cent.) showed tuberculous lesions somewhere in the body, and forty-eight of them (18.5 per cent.) showed renal tuberculosis. Of this forty-eight cases, thirty-two occurred in males and sixteen in females. Of the forty-eight cases, thirty-nine had tuberculous lesions in both kidneys, while but nine had tuberculosis of one kidney. Of these nine cases five involved the right and four the left kidney. Of the 258 tuberculous bodies it was shown that the kidneys were more commonly involved than the spleen, liver or adrenals (kidneys involved in forty-eight, spleen in thirty-two, liver in thirty-two, adrenals in eight, etc.). During the same time there were in the hospital seventy-eight cases diagnosed as renal tuberculosis, if the authorities be given the credit of making such a diagnosis in forty-eight cases where the kidneys were found to be involved in tuberculous lesions at autopsy. Of these seventy-eight cases, thirteen (16 per cent.) had nephrectomy performed, with one death occurring two months after the operation; at the autopsy the other kidney was found to be far advanced in the disease. That gave a mortality rate of 7.6 per cent. Of these thirteen cases, six fell into the speaker's hands; he had no deaths. The vast majority of cases that come to autopsy which show tuberculous lesions in the kidney were of the disseminated general miliary type, and with such a class of cases, of course, the surgeons have nothing to do with. At the present time we are sure that there is no form of medicinal, hygienic or climatic treatment that is at all curative in renal tuberculosis. The evidences at necropsies show as high as 3 or 4 per cent. of healed cases of pulmonary tuberculosis, whereas it is the rarest occurrence to find at autopsy any evidence of healed renal tuberculosis. The speaker then showed photographs of Nature's efforts in the attempt to cure renal tuberculosis. From a surgical standpoint he was satisfied that no surgeon to-day would hesitate to perform an immediate nephrectomy when he was sure that one kidney contained the only appreciable focus of the tuberculosis. Through the courtesy of his colleague, Dr. Tuttle, he was able to show a picture of a case of pseudo-tuberculosis of the kidney, a very rare condition, which was first described in 1891.

Tuberculosis of the Seminal Tract.—Dr. Hugh H. Young of Baltimore said that although tuberculosis of the seminal tract had been the subject of much investigation and discussion during the past three years, there were still wide and important differences of opipion among prominent surgeons, both as to the pathology and the treatment of the disease. The main questions at issue, he said, were these:

Is the primary localization in the epididymis, in the prostate, or in the seminal vesicles? In disease beginning in the epididymis how often does the testicle become involved, and how soon? Does the disease ever begin primarily in the bladder, and from there travel to the genital organs?

In tuberculosis of the epididymis, is castration or epididymectomy the better operation, and what are the limitations of each? Is double castration followed by important psychical or sexual disturbances? To what extent should the vas deferens be followed and removed? Is forcible avulsing advisable? With disease of the prostate and seminal vesicles, what should be the treatment? What hygienic and climatic treatment should be employed? Should the patient rest or lead an active life?

The writer presented an exhaustive resume of the literature as bearing upon the questions as above set forth, and his conclusions were as follows: The disease may begin primarily anywhere in the tract, but in the majority of instances it starts in the epididymis. The bacilli, which are constantly being carried up with the testicular secretion along the vas deferens, very soon localize in the ampulla of the vas, the ejaculatory duct, the seminal vesicle, and the adjacent portion of the prostate. The testicle is very seldom the primary point of origin, and it becomes involved secondarily to the epididymis, generally much later than the seminal vesicles, though it seems not to be so immune as formerly supposed. Tuberculosis frequently travels from the kidney to the prostate and from there involves the testicles, but it is almost never primary in the bladder.

Dr. Young spoke especially of the question of treatment when the seminal vesicles were involved. There are to be found in the literature thirty-five cases which the seminal vesicles have been removed for tuberculosis; of these fourteen will have to be excluded, because the operator failed to state the ultimate results. Of the twenty-one which were followed six died, five had recurrences of the disease, and ten were classed as well. Only eight cases were followed over one year and of these two died, two had perineal fistulas, and four were classed as cured. In only one of the six fatal cases was pulmonary involvement present before operation. Considering then that both seminal vesicles were involved in but twelve cases, the infrequency of lung and bladder tuberculosis in these thirty-five cases were not the most intensive, as such cases go, and with cures claimed in less than 50 per cent. and with only eight of these followed longer than one year, the results obtained by operative removal of tuberculous seminal vesicles are indeed unsatisfactory, and apparently not nearly so good as where a partial operation upon the external disease in the testicle alone is attempted. In his own cases he had also had poor results with spermatocystectomy, and he now believed that the prostate and seminal vesicles should not be attacked early in the disease, for the statistics of Dimitresco, Kocher, Simon, and others showed that a remarkable disappearance of prostatic and vesicular disease frequently occurred after removal of the external focus of disease by epididymectomy, or castration. In later cases, with extensive caseation and abscess formation in the prostate and vesicles, it was necessary to operate to provide a proper escape of the fluid. Dr. Young showed diagrams of a method he was now using for epididymectomy and castration. The incision was made above the groin, the inguinal canal opened, and vas divided and brought out of the upper angle of the wound, where it was sutured and left to drain exteriorly. Through this stump iodoformized glycerine injections could be made down the deferential canal to the seminal vesicles and prostate, both of which could be filled with the medicinal fluid. The forcible avulsion of the vas deferens gave a splendid opportunity for the foci situated near the deeper end to drain into the perivesical and subperitoneal space and was, therefore, to be condemned.

Tuberculosis of the Testicle.—Dr. PAUL THORNDIKE of Boston presented a short paper on tuberculosis of the testicle, based upon seventy-five cases of the disease collected from the surgical wards of the Boston City Hospital. Sixty-seven per cent. of these cases occurred between the ages of twenty and forty years; 60 per cent. of these cases involved the left testis; 18 per cent. involved both testes. Gonorrhœa had preceded the development of the disease in 30 per cent. of the cases, and trauma in 12 per cent. The epididymis alone was involved in thirty-two cases. The vas deferens was palpably involved in twelve cases. The seminal vesicles were palpably involved in sixteen cases. The prostate was palpably involved in thirteen cases. Dr. Thorndike's paper discussed two points; one, the feasibility of removing the epididymis and leaving the testis behind, in proper cases; two, the benefit to the patient of operations which removed only a part of the disease in cases where total eradication of the tubercular process is impossible.

Cases of Genitourinary Tuberculosis.—Dr. THORNDIKE showed two such cases. In the first there was a deposit in the prostate, which was not alone the only manifestation of tuberculosis of the urogenital system, but also the only one in the body. In the second case it was clearly shown that the ureter on the same side as the diseased adrenal had been infected through its mucous lining by the tubercle bacillus carried there, presumably by the urine secreted by the kidney, the adrenal of which was tuberculous.

An Analysis of Ninety-six Operations for the Relief of Tuberculosis of the Testicle.—Dr. ORVILLE HORWITZ of Philadelphia, after recounting many cases, said that he seemed warranted in presenting the following conclusions: (1) A primary tubercular infection of either the epididymis or testicle may occur, the former being by far the more common; (2) A primary infection of the epididymis, secondarily that of the testicle, is more common than the descending one; (3) Primary involvement of either the epididymis or testicle usually takes place through the circulation; the soil being predisposed to the location of the tubercle bacillus, either by a slight traumatism or by some infective condition which has given rise to inflammation of that organ; most commonly an attack of gonorrhœa; (4) Secondary tubercular involvement of the epididymis or testicle sometimes follows a primary focus of the disease in other portions of the body; more commonly in those organs that are in a direct anatomical connection with the sexual glands, such as the seminal vesicles, prostate, urethra, bladder, ureter, or kidney; (5) The invasion of the testicle may be rapid, associated with acute inflammatory symptoms, an abscess soon developing; or the onset may be slow, the symptoms simulating those of either chronic syphilitic orchitis or malignant disease of the organ; (6) The tuberculin test should always be employed in doubtful cases where only one focus of the disease is known to exist; (7) In doubtful cases, associated with hydrocele, the fluid should be examined for the tubercle bacilli, and inoculating experiments made; (8) The injections of either emulsions of iodoform or of sulphate of zinc into the diseased part are not to be recommended; (9) In all cases of encapsulated caseous nodules, quiescent in the epididymis, epididymectomy should be performed; (10) Epididymectomy together, with resection of the vas deferens, is not attended by either atrophy of the testicle or sexual weakness; (11) The drainage of tuberculous abscesses, followed by the use of the curette, is only to be-employed where radical treatment is not permissible, as it is attended with more or less danger and is generally unsatisfactory in its results. (12) In instances where the epididymis alone is involved, a resection of the diseased structure is all that is required, whether a partial or complete removal of the vas deferens is to be undertaken is still undetermined. (13) Double castration should be performed when both glands are diseased, provided there is not extensive tuberculous involvement of other organs. (14) Whether a seminal vesicle should be always removed at the time that the epididymis or testicle is removed is a question open for discussion. From the fact that in a large majority of cases the removal of the primary focus of the disease is followed by a retardation of the tuberculous involvement of the vesicles, it is deemed wiser as a rule to wait and remove the vesicles later if necessary. (15) Hygienic and climatic influences play an important part after operation in fortifying the constitution against further invasion as they do in other tubercular conditions. (16) The antitubercular remedies are of great value in controlling the disease, and should always be employed in conjunction with whatever surgical procedure may be deemed necessary.

Teratoma of the Testicle. Dr JAMES R HAYDEN of New York reported the case of a patient, twenty-seven years old, a butler who was admitted to Bellevue Hospital April 19, 1901. There was no family history of tuberculous or malignant disease. He denied ever having had syphilis, local traumatism or strain. Nine years ago he had gonorrhœa, which lasted about three months. Seven years ago he had a second attack complicated with a right-sided epididymitis which was quite severe, and since then the affected testicle has remained a little larger and harder than its fellow. Two and a half months before admission, the right testicle began to increase in size, becoming firm and hard. During the past few weeks there has been some local pain and a feeling of weakness when still, but which disappears when he walks. Upon admission his general condition was found to be good. The right half of the scrotum was occupied by a smooth, painless, heavy and densely elastic tumor, in which the epididymis and testicle proper cannot be differentiated. There was apparently no involvement of the cord, and there was no hydrocele of the tunica vaginalis. The circumference of the tumor at its largest part was eleven and three-quarters inches. The scrotum was normal in appearance and non-adherent. There was no glandular involvement. A diagnosis of malignant disease of the testicle was made, but in order to exclude the possibility of syphilis, the tumor was enveloped in strong mercurial ointment, and the patient given large doses of iodide of potassium, in spite of which, the tumor grew so rapidly that this treatment was stopped and the tumor removed. The tunica was normal in appearance, and there was no thickening of the cord, which was ligated and cut high up. The wound healed kindly without complications, and the patient left the hospital one month after admission, but failed to return again, as was requested of him.

The pathological report gave the following microscopical appearances: The growth was mostly composed of a mixture of sarcoma and carcinoma in combination with other varieties of tissue, and undoubtedly belonged to the class of teratomata. The sarcomatous tissue was both small, round celled and small spindle celled, a few giant cells being present in places. The cancer was adenocarcinoma and practically replaced all the glandular elements. A considerable cartilaginous element was seen throughout of the hyaline variety, with here and there beginning ossification. Mucous cysts were present. The connective tissue was fairly normal, but, as a whole, showed an unusual cellular element. The vessels were congested, with a proliferation of cells about them, and in parts well marked hæmorrhages were found. Smooth irregular fibres were noted, with a slight degree of fatty degeneration and some necrosis. The tumor, taken as a whole, on account of its composition and the large proportion of [illegible] and intercellular substance, was to be considered as decidedly malignant.

Gangrene of the Penis. Dr JAMES R HAYDEN of New York reported the case of a patient, fifty-seven years of age, a porter, who was admitted to Bellevue Hospital January [illegible]. Family history negative. Denies having had any form of venereal disease, local traumatism or cauterization. He was a paranoiac, holding various delusions regarding the cause and nature of his trouble, a brief history of which is as follows. About two weeks prior to his admission he noticed a small black spot on the end of the glans penis, which increased in size and gradually spread over the rest of the organ, giving rise to an offensive and penetrating odor. Upon admission, aside from his deranged mental condition, he appeared to be healthy in all respects. The entire penis, from the meatus to within one inch of the abdominal wall, was greenish black in color, dry, hard and gangrenous, with an offensive and penetrating odor. The line of demarkation was well marked. The urine passed from the under surface of about the middle of the penis. Inguinal glands not involved. The parts were frequently irrigated and dressed with hot bichloride solution, which was followed by the removal of the slough in a few days, leaving a raw and bleeding stump about one and one-half inches in length, from the end and lower border of which the urine was passed in a good stream. Healthy granulations were established, and the entire stump was then covered with small skin grafts, the favorable outcome of which was admirably shown in the accompanying photograph, showing the corpora cavernosa entirely covered with sound integument. The patient left the hospital six weeks after admission.

Officers for the Ensuing Year.—*President*, Dr Paul Thorndike of Boston, Mass., *Vice-President*, Dr Edwin C Burnett of St Louis, Mo., *Secretary and Treasurer*, Dr John Vanderpoel of New York. *Council*, Dr William T Belfield of Chicago, and James R Hayden of New York. The next place of meeting will be Washington, D C.

THE PRACTITIONERS' SOCIETY.

One hundred and seventy-first Regular Meeting, Held on Friday, April 4, 1902.

JOSEPH D BRYANT, M D, PRESIDENT, IN THE CHAIR.

A Case of Vitiligo presented by Dr HERMANN M. BIGGS. The patient was an old man, apparently feeble minded, so that no reliable history could be obtained from him. For a number of years he has been leading the life of a vagabond, wandering about the streets and living upon the scraps of food found in ash-barrels. When he entered Bellevue Hospital, several months ago, his general condition was very poor. His circulation was bad, and soon after his admission he developed gangrene in the big toe and the adjoining toe of the right foot.

The striking feature of the case is the lack of pigment in certain parts of the skin, especially over the back. These patches of vitiligo are symmetrical in distribution and their milky appearance forms a marked contrast to the dusky colored skin covering the rest of the body.

Dr Biggs said the man's blood had been examined and showed a leucocytosis running as high as 32,000, and of the leucocytes present, from 50 to 60 per cent. were eosinophiles. His urine contained an enormous number of granular casts.

Dr. BEVERLEY ROBINSON asked whether the presence of the eosinophiles pointed to a neurotic origin of the disease? Increased eosinophilia has been reported in certain nervous affections, for example, in bronchial asthma, and it would be interesting to learn whether this change in the constituents of the blood is present, as a rule, in cases of skin disease of doubtful origin.

Dr. M. Allen Starr said that eosinophilia was not a constant factor in nervous affections. It was present in some cases and absent in others.

Dr. Biggs said he had not been able to find any of these cases on record where a blood examination had been made. In skin affections, generally, eosinophilia is present, and it is attributed not so much to the particular kind of skin disease as to the extent of it.

Dr. Francis P. Kinnicutt said he had an impression that cases of vitiligo had been reported in which the number of eosinophilic cells were increased; not, however, to the extent of that observed in Dr. Biggs' case.

Dr. Edward K. Dugham, who had made an examination of the urine in Dr. Biggs's case, said that it had a specific gravity of 1,018, was acid in reaction, and contained traces of albumen and indican, but no sugar. The sediment contained immense numbers of hyaline and granular casts.

The analysis made with a view to determining the presence of an acid intoxication yielded the following results:

Total acids, in terms of sodium	5.987742 gms.
Total bases, in terms of sodium	4.182052 gms.
Excess of acids	1.8056900 gms.

This would be equivalent to 3.533 gms. of oxalic acid in the 24 hours.

The normal acidity of the urine ranges between an equivalent of 2 to 4 grams of oxalic acid per diem. This study shows that whatever modifications in metabolism may exist in Dr. Biggs' case, an acid intoxication does not exist.

A Case of Internal Derangement of the Knee-joint.—Presented by Dr. V. P. Gibney. The patient was a young man, who three years ago made a misstep, producing pain and temporary disability of the left knee-joint. Since that time he has never been able to completely straighten his left leg, and he has had recurrent attacks of disability. He complains of pain on pressure over the left external semilunar cartilage. Flexion of the limb is almost perfect, but extension cannot be carried beyond 155 or 160 degrees. The contour of the joint has changed very little and there is nothing in the synovial sac.

Dr. Robert Abbe said Dr. Gibney's case resembled one upon which he had recently operated. In that case the *x*-ray clearly showed a piece of fibro-cartilage pinched between the two cartilages of the upper and lower bones. It was egg-shaped and gave an excellent shadow. Upon excision, it proved to be a fragment of dense fibro-cartilage, which had been held in place by a very extensive external attachment. This patient had suffered from a number of attacks of disability, but since the operation the movement of the joint has been perfectly free. Dr. Abbe said his impression was that the fragment of fibro-cartilage in this case had been chipped off from one of the cartilages of the joint and had been there for a long time.

The President, Dr. Bryant, said he agreed with Dr. Abbe that the interference with the function of the joint in the case shown by Dr. Gibney was propably due to the fibro-cartilage which had either become adherent, so that it could not be moved backwards or forwards, or else it had become thickened or broken.

Dr. Robert F. Weir said that about two years ago he saw a case of intermittent disability of the knee-joint, followed by permanent fixation, with considerable tenderness posteriorly. By means of the *x*-ray a cartilage was recognized in that part of the joint, An incision was then made, opening first into a bursa over the knee-membranosis; this contained two cartilages, which evidently had slipped from the joint and had been forced into this bursa, thus acting as a hindrance to free motion of the joint.

A Case of Old Excision of the Knee-joint—presented by Dr. Bryant. The patient was a man, fifty-four years old, who entered Bellevue Hospital eighteen years ago with an extensive osteo-myelitis, attended with necrosis of the lower end of the femur, involving the knee-joint. The disease was of long standing and had produced extreme deformity of the limb. An excision of the joint was done by Dr. Bryant, and the limb fixed in a slightly flexed position; this was at that time regarded by many in authority as the best method of fixing the limb, instead of in a straight position, as is now done. After removing the joint, diseased foci were found in the lower end of the femur; these were scooped out, leaving several cavities, each about the size of a small walnut. The sawn ends of the femur and tibia were then brought together and wired, and a plaster-of-paris bandage applied, the wound being drained. The man recovered with out any complication, and the joint gave him no further trouble until six months ago. Then he developed a sinus in the popliteal region, evidently due to the presence of dead bone at the lower end of the femur.

Dr. Bryant said that this operation, done eighteen years ago, was his second case of excision of the knee-joint. Altogether, he had done this operation twenty-five times, and all of them made a prompt recovery, with two exceptions. One of these died of exhaustion from suppuration, while in the other case the popliteal artery was accidentally opened while dissecting out diseased tissue in the popliteal space, necessitating prompt amputation. In but two of his cases—first two—the limb was put up in a flexed position.

In reply to a question as to whether he would now put the limb in a straight position in case another operation was undertaken, Dr. Bryant said he would be guided by the condition of the lower end of the femur. The man has become accustomed to the present position of the limb. and he did not think it advisable to alter it unless he could benefit the stability of the lower end of the femur by doing so.

A Case for Diagnosis—presented by Dr. Weir. The patient was a young woman with a subcutaneous swelling of the right side of the face, extending from the temple to just below the jaw and from the ear nearly to the angle of the mouth. This had first been noticed, about three years ago, as a slight puffiness just anterior to the ear, and had gradually extended downwards to the lower jaw and upwards, involving the eyelids, so that now the eye is entirely closed. There are a few enlarged glands in the neck. The swelling is hard to the touch, the skin adherent to it and anteriorly and inferiorly the edges can be clearly outlined by palpation, and resembles a slowly progressing lymphatic trouble. Its color is whiter than normal skin and mottled with pearl areas. The patient suffers no pain and is otherwise in good health. The swelling of the eyelids, she states, came on in September last. Dr. Weir said the case was possibly one of obscure sarcoma or lymph œdema, with rather unusual features. It also bears some resemblance to the form of chronic urticaria described by the French dermatologists.

Dr. Robert Abbe said the case resembled an elephantiasis from lymph infection or lymph œdema, the focus of infection possibly being a diseased tooth, of which the patient gives a history. Several months ago, the speaker said, he showed a number of cases with a somewhat similar condition, the lymph œdema being confined to the lower extremity, and probably originating from an infecttion of the deep lymphatics. In erysipelatous infections we sometimes get a condition resembling this, excepting that the swelling is not quite so hard.

Dr. Kinnicutt said the hardness of the lesion in this case was so pronounced that it was almost an induration, and this, he thought, would rather militate against the [illegible] that it had a [illegible]. The swelling of the [illegible] somewhat resembles a [illegible], but the [illegible] projecting edge of the [illegible] is too hard to indicate such a condition.

Dr. Abbe said that while it was rather unusual to see such a hard border in cases of [illegible], yet it might occur. Following the [illegible] in these cases [illegible] changes are likely to take place.

Dr. Kammerer said that in this case the growth is spreading at the periphery, and we would not expect to find the present hardness there if the condition [illegible] of [illegible].

Joint Derangements, Due to Movable Bodies, Defective Cartilages, Etc., in Joints.—By Dr. Joseph D. Bryant.

Dr. Edward K. Dunham, who had made a gross and microscopical examination of the movable body removed from the joint in one of the cases reported by Dr. Bryant, said that it appeared to have a bony surface throughout, without any interruptions that could be detected. This bony shell was continuous with a cancellated bony structure, forming the interior of the specimen, the spaces between the bony plates being filled with fatty marrow, quite like the normal marrow of bone and well supplied with blood vessels. The surface of the bony plates within and without were covered with a layer of cells resembling those of the periosteum and endosteum of normal bone, and there was some fibrous tissue covering the surface of the bone externally. There were no evidences of any inflammatory or necrotic process, nor of any cartilage.

Dr. Dunham said the structure seemed of interest in view of the light it might throw on the etiology of this movable joint body. He had examined the records of [illegible] cases of loose joint bodies where the microscopic structure of these bodies was described, and in the majority of them the specimens consisted of both cartilage and bone, either hyaline cartilage or fibro-cartilage being present. In some instances the body was found to consist entirely of bone, but these were cases of arthritis deformans. In such cases the bone contained but few vessels as a rule. It is usually quite dense and frequently necrotic.

Dr. Dunham said the structure of the specimen he examined did not agree with that of any of those recorded. If the body is a piece of normal or diseased bone, one would expect to find cartilage present or evidences of inflammation, but neither of these were found. Arthritis deformans can be excluded in this case by the patient's history, as well as by the structure of the specimen. The body is probably a small osteoma which became pedunculated and remained attached only by a very small pedicle.

Dr. Abbe said he had seen perhaps eight or ten cases of loose cartilage in the joints, and taken out three or four of them under cocaine anæsthesia. One case was that of a young man who received a blow over the knee with a hockey stick. For three days he limped about with a stiff, slightly bent knee and some synovitis. An incision showed that the fixation was due to a wedge-shaped fragment of cartilage, about three-quarters of an inch long, which had been chipped from the inner side of the knee. One facet of the fragment presented a gritty bony surface. In the course of time, Dr. Abbe said, such a fragment might readily become covered with cartilage on all sides and thus resemble some of the so-called loose cartilages.

Dr. Robinson said that in a case of movable body in the knee-joint, which came under his care about a year ago, the patient made an ultimate recovery without surgical interference by wearing a knee-cap made of stiff canvas.

Dr. McBurney said that he agreed with the view which is held by most pathologists, that many of these loose bodies—perhaps the majority—are formed from portions of the synovial fringes, which, having being subjected to traumatism and possibly [illegible] progressive inflammatory changes, finally become loose in the joint. Some of the specimens had, with [illegible], such an origin. In operating on the knee for other causes one frequently saw synovial fringes in various stages of proliferation, sometimes in the shape of well-defined bodies either entirely loose or hanging by a mere thread. The bony changes doubtless occur here as they sometimes occur after traumatism in other parts of the body.

Dr. McBurney said that about a year ago he saw a young woman of eighteen who suffered from severe pain and disability of the right knee joint, which had extended over a considerable time. She could neither walk nor ride with any comfort, and very frequently the joint became locked in the semiflexed position, causing a great deal of pain. The history was clearly one of a loose body in the joint, but in spite of repeated examinations it could never be detected. On the inner side of the joint localized pain could be elicited on pressure, and a slight localized fulness was made out. On opening the joint in this region a mass of synovial fringe was found about the thickness of the little finger, and with a very broad attachment. It was firm and considerably thickened, and showed evidence of having been subjected to a good deal of traumatism. No other suspicious body could be found. The tissue described was removed, and since the operation the patient has never had any symptoms referable to the joint.

Dr. Gibney referred to the cases of so-called traumatic arthritis not infrequently met with in young persons, where there is at times locking of the joint, with much discomfort and disability, and thickening and tenderness, either on the inner or outer side of the patella. When in addition to these symptoms, there is marked atrophy of the thigh or calf muscles, with reflex spasm and bony enlargement, tuberculosis of the joint should at least be suspected.

In the class of cases discussed by Dr. Bryant it is not necessary always to have a complete luxation of the cartilage to cause trouble, a slight subluxation or a rupture of some of the fibres may be all that exists. If the history of each individual case is carefully inquired into, the original lesion can usually be pretty accurately reasoned out. As regards treatment, after these patients have been relieved for a time by various appliances, it is usually difficult to induce them to submit to an operation. The operation itself is comparatively simple, but the danger heretofore has been that too much exploration is indulged in after the joint has been opened, and thus the danger of infection, with serious consequences, is increased. There are cases, both recorded and unrecorded, where amputation has become necessary after simple exploration of the joint for the removal of a loose body.

Dr. Gibney said he was convinced that many cases of so-called traumatic arthritis of various types could more properly be classified as cases of loose bodies in the joint, pedunculated synovial fringes, interference with the bursa, and other lesions that are now generally known as internal derangements of the joint.

Dr. Weir said that he had never seen a single instance, in his own work, where the nucleus of a loose body in the joint was composed of cartilage, with or without a bony nucleus; they all, apparently, originated from the fimbriated synovial membrane, excepting in six cases. Three of the latter were fleshy masses, pedunculated, and upon examination they proved to be sarcomatous, probably mixed with inflammatory elements. In none of these cases, however, did a recurrence take place after removal. The three others were fatty growths which sprang from without the joint, either from underneath the ligamentum patellæ or in front of the femur. These masses when so entering the joint gradually harden, become mixed with effusions of blood, and often resemble the sarcomata. Two of these fatty growths were pedunculated. All these patients made a perfect recovery after operation.

Dr. Weir said he had seen recently two cases of chronic arthritis with multiple loose cartilages. In one of these cases there were four loose bodies and in the other five. In these the disability, though not great, brought up the consideration of an operation. This was negative mainly because of the probable inability to discover and remove all the offending bodies without too much damage to the joint.

THE MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Stated Meeting, Held April 28, 1902.

FRANK VAN FLEET, M.D., PRESIDENT.

Defects of Vision the Result of Certain Drugs, Drug Habits and Occupations; Their Recognition and Treatment.—Dr. G. E. DE SCHWEINITZ of Philadelphia was the author of this paper. He said that the term amblyopia was usually applied to cases in which the disturbance was moderate, and the term amaurosis to cases in which the disturbance was more severe.

Quinine Amblyopia.—By far the most interesting of these amblyopias was that produced by quinine. It appeared in four ways: (1) As a temporary quinine blindness; (2) As an acute quinine blindness; (3) Relapsing quinine blindness, and (4) Permanent quinine blindness. The first form usually occurred in nervous individuals, especially women. The acute blindness usually developed after a single large dose of quinine, or after large doses on successive days, *e. e.* sixty to eighty grains or one hundred grains of quinine. This form of blindness was characterized by a more sudden and complete extinguishment of sight than in any other form of blindness which may be recovered from. It made no difference what preparation of quinine was administered, there would be found a blanching of the retina and great pallor of the optic disk, and usually a narrowing of the visual field. Dr. Ward A. Holden of New York had shown that, in animals at least, the primary lesion was a direct degeneration of the ganglion cells of the retina, probably caused by the intense ischæmia produced by the quinine. His personal belief was that there was a selective action on the ganglion cells of the retina. The treatment usually consisted in the withdrawal of the quinine and the administration of such drugs as digitalis, nitrite of amyl and strychnine. Quinine blindness was very similar to that caused by the salicylates and by salicylic acid, and hence it was probable that in both of these affections the same action took place on the ganglion cells of the retina. Antifebrin and antipyrin would produce the same result, the former in more marked degree.

Iodoform Amblyopia.—A number of cases of iodoform amblyopia had been reported in which the effect on the eye had been produced both by the absorption of the iodoform from surgical dressings and by the administration of this drug by the mouth. It was worthy of note that in the case of iodoform, as in that of quinine, that the dosage producing the amblyopia varied within very wide limits. The iodoform amblyopia in rare instances had been permanent. It was perfectly possible that some cases of so-called iodoform amblyopia had been the result of other causes, as for example, in cases of extensive burns, in which iodoform had been used in the dressings.

Thyroid Extract.—Some recent observations went to show that the continued use of thyroid extract produces an amblyopia similar to some of the toxic amblyopias. The condition disappears on the withdrawal of the extract and the use of some tonic.

Alcohol Amblyopia.—This form of amblyopia should be considered under two heads, the acute and the chronic. There was a difference also between the acute amblyopia from ordinary alcohol and that resulting from the use of methyl alcohol. Only two drachms of the latter had been known to cause blindness. In a large number of instances it produces first some gastrointestinal disturbance and delirium, and perhaps unconsciousness, ending in blindness. In about 90 per cent. of the cases the vision was permanently damaged. The essence of Jamaica ginger, the essence of peppermint and bay rum had all been known to give rise to similar effects. The active agent in these substances had been found to be an adulteration with methyl alcohol. The original coma sometimes ends in death. Methyl alcohol produced blindness by its action on the ganglion cells, as shown by Dr. Holden. It was quite probable that there was a simultaneous degeneration of the fibres of the optic nerve. Some cases, when seen early, recover under prompt treatment. Of the various methods, the best were those in which the essential feature was sweating produced by pilocarpin, followed by the hypodermic use of strychnine. About 10 per cent. recover with some sight.

Alcohol-Tobacco Amblyopia.—One could not consider chronic alcoholic amblyopia apart from that produced by tobacco, so that it was perhaps well to speak of this affection merely as an intoxication amblyopia. He thought alcohol when taken internally predisposed one to amblyopia, particularly if poor alcoholic liquors were used and were taken on an empty stomach. It was impossible to say what was the safe dose of tobacco, because of the great individual differences. Certain strong forms of tobacco, particularly if smoked in a pipe and on an empty stomach, were especially likely to give rise to amblyopia. Ordinarly some years elapse before vision becomes affected. The patient observes an indescribable fog over everything. Examination with the ophthalmoscope showed a pallor of the optic nerve and the field of vision with a central scotoma for red and green. If the person continued to use alcohol there was nearly always a depreciation of the vision. The modern belief was that the primary change was not in the axis of the optic nerve, but that the ganglion cells of the macular region first become degenerated, and this is followed by an ascending degeneration. The same general treatment previously indicated was appropriate for these cases, The active agent of tobacco amblyopia was still a matter of dispute. It used to be thought that the active cause was nicotine, but tobacco contains a number of powerful substances, and the special principle causing the amblyopia is not yet known. A certain number of cases of central scotomy credited to tobacco or alcohol should probably be attributed to other causes. A certain number of these cases probably represented an early stage of disseminated sclerosis. It was rather curious that at the beginning of the impairment of vision the usual toxic symptoms of tobacco, such as tachycardia, were not present, though they very soon made their appearance. Again, it was not uncommon to find an associated Bright's disease, and this was particularly apt to lead the physician to think this was the sole cause, and so overlook the part played by the tobacco.

Occupation Amblyopias.—In lead poisoning there might be a temporary amblyopia, an optic neuritis or a nerve atrophy, and finally a retinitis. Lead produces very widespread changes in the ganglion cells of the retina and of the whole cerebrospinal axis. It also causes a marked obliterating endarteritis. Not infrequently among seamstresses lead poisoning arises from the biting of silk threads which are coated with lead compounds. An interesting form of amblyopia was that occurring among rubber workers from the inhalation of the fumes of bisulphide of carbon. As a rule, the amblyopia did not develop until the person had been engaged in this occupation for months or years. Another form of amblyopia was that produced by nitrobenzole or by dinitrobenzole. Of course, a certain number of drug amblyopias were really occupation amblyopias. For example, tobacco workers sometimes develop amblyopia, and the same was true of persons engaged in varnish works, hat factories and other places in which wood alcohol is largely used.

Injuries to the Eye and Their Treatment.—Dr. J.

MEADOWS RAY of Louisville, Ky., read a paper on this subject. He said that wounds of the eyeball were serious in proportion to their nearness to the ciliary body. In penetrating wounds of the eyeball the management of the wound and of the protruding structures must be carefully considered, also the danger of sympathetic involvement or the necessity for immediate enucleation. If there was only a prolapse of the iris and the case were seen in a few hours, an attempt could be made to replace it after very thorough cleansing and disinfection. If the iris were lacerated it should be excised. The lips of the wound were then coaptated and a bandage applied. No reliance should be placed upon mydriatics for the purpose of withdrawing the iris from the wound. When the wound involved the sclera, asepsis was even more important than when the cornea was involved. He thought enough importance was not attached to the grave possibilities of an inflamed eye. It was often desirable to cut a narrow-based conjunctival flap and dissect it up external to the line of incision, and then stitch it over the wound. The speaker said he felt sure that he had seen eyes saved from complete destruction by this procedure. When the injury was confined to the ciliary zone and the division of tissue was not great, the injury was the gravest of all to which the eye was subject. These injuries were usually made by a sharp object, such as the tine of a fork, and the penetration was usually deep. The vitreous usually contained large quantities of blood and thus afforded an admirable culture medium for the infectious matter carried into the eye by the object inflicting the injury. The best local application to limit the reaction was cold.

Foreign Bodies.—In penetrating wounds where the presence of a foreign body was suspected, an exact diagnosis was of much importance. The history of the case, the appearance of the eye and the tenderness of the region would aid the physician. Positive evidence was fortunately now at our command by the use of the x-ray. In his experience the most dangerous injuries of this kind were those in which particles of stone had been driven into the eye. In making the prognosis one must take into consideration the location of the injury and the possibility of infection. The most hopeful cases were those in which the foreign particle had penetrated the cornea and lodged in the iris or anterior chamber. When the foreign body had penetrated more deeply, the danger would depend chiefly upon the nature of the body. The application of the large electromagnet for the removal of particles of iron was a triumph of modern ophthalmology. The sooner the magnet was used after the injury the greater the chance of removing the foreign body and the less the chance of infection. After forty-eight hours or more, the foreign body would become embedded in lymph and the magnet would often fail to dislodge the particle.

Sympathetic Ophthalmia.—In no other part of the body was there a condition analogous to sympathetic ophthalmia. The most frequently observed form was a plastic inflammation of the uveal tract, characterized by ciliary injection and dust-like opacities in the vitreous. Later on there would be found adhesions of the lens capsule, and finally vision would be destroyed. The shortest time after the receipt of an injury, in which sympathetic ophthalmia had been noted, was fourteen days, but it might occur after a period of years. Children were particularly susceptible to it. The speaker said that he had seen it develop only once in an experience of fifteen years. In deciding upon the question of enucleation, one must consider this danger. An opportunity should be given for repair of the wound, guarding carefully against infection. If the wound healed kindly without infection the danger of involvement of the fellow eye was not great. If the wound did not heal well, or afterwards there was evidence of inflammation the eye should be removed without delay. Harmless blind eyes were better than glass eyes for prothesis. When the eye was removed in childhood and an artificial eye substituted he had found a defective development of the orbit and facial region on that side. Moreover, the removal of one eye placed the person at a great disadvantage in the battle for a livelihood.

Contagious Conjunctivitis.—Dr. MYLES STANDISH of Boston presented this paper. He spoke of the signs and symptoms of catarrhal conjunctivitis, and then stated that, according to his experience, the disease could be best aborted by dusting into the conjunctival sac every twelve hours for two or three times finely powdered and dry iodoform. Dr. Standish also considered trachoma, gonorrhœal ophthalmia and diphtheritic conjunctivitis.

Trachoma.—He stated his own belief in the moderate contagiousness of trachoma, and said he could not understand how any one who had seen the disease spread through families could doubt that it was contagious. Confusion arose from confounding trachoma with follicular conjunctivitis. The latter presented low rounded follicles principally in the lower conjunctival sac, and was rarely seen on the conjunctiva of the upper lid. On the other hand trachoma presented rather round, frog-spawn-like bodies appearing first on the fornix of the upper lid and then spreading over the whole conjunctival surface of the lid and perhaps on to the lower lid. It was a disease which, according to the methods of twenty years ago, lasted usually for many years. Fortunately, about fifteen years ago, the practice of surgically removing trachoma had come into vogue. The method of expression was a good one, but after this manipulation the follicles should be vigorously rubbed with a 1 to 500 solution of bichloride of mercury, applied with a cotton ball on a stick. The patient was able to continue at work, and if the treatment were persevered in for a year or two the patient would be absolutely cured and without having the extensive scarring observed under the older methods of treatment. In 1897 the speaker said he had presented a paper to the Massachusetts Medical Society urging that immigrants suffering from trachoma be excluded, and this suggestion had afterwards been acted upon. In order to form some conception of the amount of trachoma in the community, he had collected statistics from the case books of the Massachusetts Charitable Eye and Ear Infirmary, an institution practically representing the ophthalmic practice of the city of Boston. For the five years, 1890-1894, the cases of trachoma constituted 4.5 per cent. of a total of 35,280 cases, whereas in the last five years, 1897-1901, the percentage was only 1.2 per cent. of a total of 112,638 cases. This improvement in the statistics was not entirely dependent upon the exclusion of immigrants having trachoma, but upon better methods of treatment, as shown by the figures showing the number of days of hospital care.

Gonorrhœal Ophthalmia.—The treatment of this disease had also greatly improved in the ophthalmic hospital already referred to. Formerly these cases had all been treated in the out-patient department, and the blind rate had been large. The first case of gonorrhœal ophthalmia admitted to the wards was in 1876, and at that time only a few severe cases were admitted, and these with their mothers to take care of them. In 1896 a special ward was provided and all applying for treatment for gonorrhœal ophthalmia were either forced to enter this ward with the mother or were refused treatment. The principal remedy for the last twenty years had been the nitrate of silver, which in the strength of a 1 or 2 per cent. solution had been painted upon the conjunctiva. More recently a solution of protargol had been used to flush out the conjunctival sac and with distinctly better results. In fifty cases in which nitrate of silver had been exclusively used, there were 6 per cent. of unsuccessful cases. In 150 cases in which protargol was the only remedy used there were only 2 per cent. of unsuccessful cases. The strength of the protargol solution had steadily increased from 4 to 20 per cent., the strength now employed. In the last fifty cases so treated there was not a single child, having a clear cornea on admission to hospital, which did not leave the hospital without any corneal complication. The protargol irrigation was repeated once in three hours. However, when there was a corneal ulcer present at the time of coming under observation, the protargol did not exhibit any special controlling power over the ulceration.

Diphtheritic Conjunctivitis.—This disease began with marked velvety condition of the conjunctiva of both lids, lachrymation and almost no mucus discharge for the first three or four days. At this stage it was impossible to make the diagnosis from the local appearances. As the disease progressed the lid became greatly swollen, and a dirty tough membrane appeared. The diagnosis was only made positive by finding the Klebs-Loeffler bacillus in the secretions. In 1889 it had been the general opinion of the profession that no mode of treatment was successful. His own method of treatment in recent years had been to give large doses (4,000 units) of diphtheria antitoxin, often repeated several times. After forty-eight hours there was no longer any occasion for anxiety about the eye. When corneal ulceration was present it was favorably affected by diphtheria antitoxin.

The Microscopical Examination of Conjunctival Discharge in Contagious Diseases ot the Eye.—Dr. Edgar S. Thomson of New York presented a brief paper on this subject as a supplement to the contribution of Dr. Standish. He said that the pus should be taken with a platinum loop and spread upon a glass slide. It was important to take the pus from the cul-de-sac and not from the edge of the lid, and also to spread the pus very gently. He advised rapid staining with Loeffler's methylene blue, drying and examining with a one-twelfth oil immersion lens. If a deeply-stained, encapsulated diplococcus of characteristic shape were seen lying chiefly within the cells, the diagnosis of gonorrhœal conjunctivitis was usually warranted. It could only be mistaken for the diplococcus of meningitis. The latter was usually found outside of the cells. Where there was doubt, cultures should be made. The Klebs-Loeffler bacillus was rarely found in the secretions from the conjunctiva, and when a bacillus having its morphological characteristics was observed, culture experiments were required to settle the diagnosis. The Weeks' bacillus was by far the commonest organism found in "pink eye," and was readily recognized by slide examination. Illustrative specimens were presented under the microscope.

Dr. Charles Stedman Bull, speaking of the first paper, said that he had been deeply interested in the remarks on quinine amblyopia, having himself suffered from it at one time. Having contracted malaria in Missouri he was given thirty grains of quinine three times a day for four days. His vision was then reduced to 10-200ths and the optic nerve was white. It was nearly seven weeks before vision returned, and he could confirm what Dr. De Schweinitz had said about such an attack leaving one subsequently very sensitive to the action of quinine. He had never seen iodoform amblyopia, except in connection with absorption of this drug from the surface of the body. He had observed one case of methyl alcohol amblyopia occurring in a wood chopper who had bought what he supposed to be whiskey, but which was proved to consist chiefly of methyl alcohol. The man remained in coma for two days and after that was permanently blind. Dr. Bull said he had seen two cases of tea amblyopia, both of them in the female wards of the almshouse. It was never easy to diagnose lead amblyopia, because it almost always occurred in persons who made free use of both alcohol and tobacco.

Dr. D. B. St. John Roosa discussed Dr. Ray's paper. He emphasized the fact that the danger line in injuries of the eye was the ciliary region. Although great progress had been made in the removal of particles of iron and steel from the eye, sufficient time had not elapsed to make a complete classification of the cases in which early removal in this way had been effected and the ultimate result had been observed. Ophthalmologists should still be exceedingly cautious in cases of infected wounds of the eye, and in the case of any wounds, infected or not, in the ciliary region. Sympathetic ophthalmia he characterized as still a *terra incognita*, for even bacteriology had not discovered the method of transference in cases of sympathetic ophthalmia.

Dr. Hermann Knapp took up the discussion of the paper of Dr. Standish. He said that the pathology of trachoma was not yet clear. There were two forms distinguished as folliculosa and granulosa. Between the follicular and the ordinary granular trachoma there was only one step, and it was not known in what way the follicle differed from the granule. No one had yet found any microbe or bacillus in connection with either of them. The histological entity was the granule. The disease was curable in itself, and its malignancy, in his opinion, must depend upon some infection. These diseases, in the absence of infection, recovered even without treatment. If the follicles were at all numerous recovery did not take place, as had been said, without cicatrices. In the older cases both lids were markedly granular, and yet unattended by inflammation, so that in some instances the person was not even aware of the presence of this condition. There was an innocent form, known as acute trachoma, in which the microbes were not mischievous. By personal observation he had found in some of the best schools of Egypt that no less than 92 per cent. of the children presented cicatrices on the eyelids. In July and August in each year there is an epidemic there of ophthalmia, either gonorrhœal or mixed with other microbes, which give rise to these scars.

Silver Harmful at Beginning of Gonorrhœal Ophthalmia.—The preventive treatment by the Credé method was most important. Not only should a 2 per cent. solution of nitrate of silver be instilled into the eye, but the eyelashes and the outside of the lids should be washed with the same solution. It was very rare, indeed, for the eyes to be injured by this treatment. The treatment of the first stage of gonorrhœal ophthalmia by nitrate of silver was, in his opinion, most reprehensible. In the healthy eye of a child even a strong solution of nitrate of silver would do no harm; but in gonorrhœal ophthalmia, before the stage of suppuration had begun, the use of even a 2 per cent. solution of nitrate of silver would irritate the eye without doing any good. The silver solution should not be used until the dense infiltrate around the cornea had softened and the swelling of the conjunctiva had diminished. In this first stage the treatment should be strictly antiphlogistic. As soon as this stage had passed there would be a purulent discharge, and then the nitrate of silver should be used. He did not believe in cutting through the conjunctival ulcer; treat the conjunctiva properly and the ulcer would take care of itself.

Protection for Well Eyes.—He had found the best means of protecting the healthy eye was by the application of a shield of mica, held in place by strips of adhesive plaster.

Dr. Standish, in closing, said that the fact that the exact nature of trachoma was not understood was no argument against its being infectious. Regarding the protecting shield, he would say that it was not applicable to children.

The Lincoln Hospital.—The name of the Colored Home and Hospital of this city has been changed to the "Lincoln Home and Hospital." The hospital has recently been designated as an ambulance station by the city authorities, and the ambulance service will be provided for in the emergency ward.

Medical Items.

Contagious Diseases Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, New York City, for the week ending May [illegible].

	Cases	Deaths
Measles	45[illegible]	[illegible]
Diphtheria and croup	281	44
Scarlet fever	[illegible]	[illegible]
Smallpox	58	[illegible]
Varicella	68	
Tuberculosis	[illegible]	[illegible]
Typhoid fever	21	14
Cerebro-spinal meningitis		3

Mouth Washes.—Max L[illegible] describes the results of a very elaborate series of observations made to determine the absolute and relative values of a number of the proprietary mouth washes in common use. In contradistinction to those authors who have considered the habitual use of such preparations injurious owing to the destruction of the lining epithelium of the mouth it entails, he believes that desquamation of these cells goes on constantly as a physiological process and is not stimulated to a harmful degree by mouth washes. In all cases it was found that the rinsings contained enormous numbers of bacteria, and also that their growth was but slightly influenced by the presence of the mouth wash that had been employed. A marked difference in effect between the various preparations was, however, noticeable, only two of the large number examined exhibiting appreciable antiseptic properties. Of these, one containing formalin far surpassed the other, the tests showing an average of forty-four colonies as against one thousand and fifty-nine. The presence of formalin in such preparations is not at all injurious but a distinct advantage.—*Centralblatt für Bakteriologie, Parasitenkunde und Infektionskrankheiten.*

Suprapubic Cystoscopy.—P. Kraske employed this method of exploring the bladder in two cases in which a suprapubic opening had been made for therapeutic reasons and was so pleased with the results that he made further trials which led him to recommend the measure as one adapted to frequent application. It is particularly cases in which the introduction of the instrument by the urethral route is difficult or unsatisfactory that can be examined with advantage in this way, while the performance of all intravesical operations, such as Bottini's, for prostatic hypertrophy can be admirably controlled. In practice the ordinary curved vesical trocar may be used, the canal being dilated with laminaria tents sufficiently to admit the passage of the instrument, or a trocar of such caliber may be chosen that the cystoscope can be slipped in through the canula. The author has devised a special form of cystoscope, with detachable trocar point, which permits the instrument's removal and reinsertion from time to time for the purpose of irrigating the bladder and washing out blood or mucus obstructing the view.—*Centralblatt für Chirurgie.*

The Continued Fevers of the South.—W. A. Evans, from his studies of about forty-nine cases, concludes that there is no such disease as the so-called febris innominata. In regard to combination fever or typho-malarial, most of the cases are of true typhoid. Typhoid fever in a malarial district is modified as to its symptomatology by malaria. The author is not prepared to state whether this modification occurs in the bacillus outside the human body, in the bacillus in the human body, in the human body itself, due to acute or chronic malarial intoxication, to nervous habit begotten from repeated malarial attacks, or to the effects of prolonged high temperature. The post-malarial continued fevers are usually malarias pure and simple. These have been most thoroughly studied by Bastianelli, Bignami, and Marchiafava. The continued fevers left after the above have been subtracted are of the following groups: Septicemias (so-called cryptogenetic), tuberculosis, pulmonary and miliary, intestinal [illegible] and diarrheas.—*Memphis Medical Monthly*, April, 1902.

Health Reports.—The following cases of smallpox, yellow fever, cholera, and plague have been reported to the Surgeon-General, U. S. Marine-Hospital Service, during the week ended May [illegible], 1902:

SMALLPOX—UNITED STATES		Cases	Deaths
Alabama: Birmingham	May [illegible]	[illegible]	
California: San Francisco	Apr [illegible]	[illegible]	
[illegible]	Apr [illegible]	[illegible]

RADIOTHERAPY FOR CANCER AND OTHER DISEASES*

By WILLIAM J. MORTON, M.D.,
NEW YORK.

PROFESSOR OF ELECTRO-THERAPEUTICS AND DISEASES OF THE MIND AND NERVOUS SYSTEM, NEW YORK POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL.

It is with great pleasure that I have accepted the suggestion to read a paper relating to the *x*-ray before our association. The twentieth century is offering to us an ever newer and broader science of medicine. This new medicine is not one built on theories, but rather one which keeps pace, step by step, with the unraveling of the physical problems of matter. Each new discovery in physics is seized upon by trained medical minds and applied to medical practice. But so long as chemistry stood on an isolated pedestal as a medical entity, so long medication by drugs alone seemed impregnable in its therapeutical fortress.

But to-day, when chemical affinity falls into line as an electrical phenomenon, when placing the rate of vibration of electricity at the lowest end of the scale, we may ascend upward through the vibrations of heat, of the visible spectrum, of the actinic rays, of uranium radiation, and, finally, to the Röntgen radiation—we are forced to a larger conception of therapeutics, and forced to admit that medicines are but a part of a much greater whole, whose inclusive title might be simply "physical therapeutics."

The twentieth century dawns with a new conception of the ion or the elektron and ionization; with new conceptions of the relation of electricity to life and health and disease, and with new conceptions of radiations in their applications to the treatment of disease.

Prominent among these new therapeutic contions is that of radiotherapy, and we may well pause here and express our profound gratitude to Prof. Röntgen for his discovery, whose beneficent influence in medical practice at the present moment bids fair to rival its interest to pure physical science, and our equal gratitude to Prof. Finsen, who, in relation to Radiotherapy, may well be termed the Apostle of Light. But while Röntgen's discovery came into the world in great completeness, the therapeutics of his discovery, except for purposes of diagnosis, have been of slow development. True, marvelous claims were at first heralded, but these have given place to sober second thought. It is admitted to-day that the *x*-ray has in a certain number of instances cured cases of every form of malignant growth and that it cures lupus. Also eczema, psoriasis, prurigo, acne vulgaris, sycosis, favus, rosacea, and tuberculous foci have been cured by the *x*-ray.

If we go no further than this, we are at once struck by the fact that it is in just those diseases and conditions least amenable to our former treatment that the *x*-ray scores its most signal successes.

But the *x*-ray has also a promise of extreme utility in pulmonary tuberculosis; it has a remarkable effect in relieving pain; it assists in healing burns, wounds, ulcers and sores, and its curative effects reach internal diseases.

For these reasons I believe that a few observations from me, relating to technique and indications, may be worthy of attention.

I. Technique.—The therapeutic use of the *x*-radiation is based upon the fundamental fact that this radiation exerts a specific influence upon the life-processes of animal and vegetable tissue. This influence is beyond dispute: it is most openly manifested when exerted upon the integument, but laboratory experiments show beyond question that small animals, like mice and guinea pigs, weeks after irradiation, unnoticed by them at the time, suffer internal structural changes, which even end in their death, and may be likewise demonstrated post mortem. These structural changes are invariably of the type of ordinary inflammation. Kaposi, indeed, expresses the view that all the changes thus far noted, whether of the integument or internal, differ in no wise from common inflammation. Dr. Carl Beck reports that in the case of mice irradiated by him by the *x*-ray, the autopsy showed congestion and, microscopically, signs of inflammatory changes in the viscera. Tarchanoff has reported that mice, guinea-pigs, rabbits and birds died after prolonged irradiation, exhibiting paralytic symptoms. It is not our purpose, however, to enumerate in detail the various pathological and physiological changes in living animals already demonstrated as the direct and inevitable effects of *x*-ray irradiation.

But the sole point I wish to emphasize here, and it is an important one, is that Radiotherapy is by no means, as seems to be commonly believed, to be confined to exterior and superficial diseases and conditions, but is equally applicable to diseases of the interior, like internal cancer, and, in general, to internal diseases.

Included in the specific influence of *x*-radiation is also naturally a bactericidal action, which the experiments of Rieder and many others have established beyond doubt. Granting our basis of a specific influence of the type and kind above described, we may next consider: (1) The active agency, namely, the *x*-ray; (2) The disease; (3) The source of energy; (4) The vacuum tube; (5) The effect of the exposure; (6) The time and other conditions of exposure.

The x-Ray.—Antecedent to the production of the *x*-ray is an electric current of high potential, a vacuum tube, and the production of a cathode ray. The cathode rays are held to be streams of material particles torn off from the negative electrode, each particle not an atom in the usual sense of the word, but rather primary atoms of the primary matter out of which the ordinary atoms are formed, each primary atom or particle constituting a carrier of negative electricity. When the cathodic stream strikes the platinum mirror or other sort of target, a new sort of radiation is established, called by Röntgen the x-radiation. This new radiation is considered both by Röntgen and Lenard to be in all probability of the same nature as the cathodic stream, differing only in the mode of radiation, while on the other hand other physicists claim that it is an ether vibration of the nature of light, but of much shorter wave length. Of most interest to those of us who wish to apply the x-rays in practice is the view of Professor J. J. Thompson, that they are a mixture of vibrations, which may be termed "pulsations of the ether," and may be compared to the irregular pulsations of the air in producing those sound waves which we term "noise." This would account for the very great uncertainty which we cannot deny, exists in the effects of the x-ray when utilized for treatment.

---

*Read at a stated meeting of the Medical Association of the Greater City of New York.

But whether we regard the x-ray as an ether vibration or as a storm of material particles, certain it is that, in a given vacuum, it is seldom, for any length of time, of one and the same quality. It runs up and down a scale whose rates we cannot now determine. To add to our uncertainties, we must also take into account the S-rays and the Goldstein rays, each, respectively, secondary productions of the x and of the cathodic rays.

It is the x-ray itself which sets up dermatitis, produces necrosis, or, when properly used, cures disease. The cathode rays do not escape from the vacuum tube. I cannot believe that, as claimed, the electric pulsations given off from the tube exert a harmful influence. On the contrary, I believe that they benefit the patient, in accordance with the well-known laws of the therapeutic effects of high potential currents. In this respect, indeed, they should act as an offset to any baleful influence of the *x*-ray, and possibly, at times, to its curative influence. Regarding the electric vibration, therefore, in this light, I do not consider it essential to employ an aluminum grounded screen, or if I should employ the screen, it would be for the purpose of cutting off the beneficial, not the harmful, effects of the x-ray.

2. *Cancer.*—Turning to a consideration of the principal disease to which we would apply the *x*-ray, it would greatly hasten therapeutic progress if we had any adequate knowledge of what the pathology of cancer is. However, in this respect the physician can be said to be groping in no less ignorance than is the physicist, in regard to the true nature of his x-ray.

As practitioners, therefore, our attitude must be almost entirely empirical and clinical, and we must feel our way along with careful experimentation and observation.

3. *Source of Electrical Energy.*—A Rumpkorff coil, a static machine, or an oscillator provides this, with, so far as is known, no demonstrable differences in the quality of the *x*-ray produced.

4. *The Vacuum Tube.*—The Crookes-Jackson vacuum tube with platinum deflector is the universally adopted type of tube. It should be provided with a spark-gap device, by which the vacuum is lowered by chemicals in an adjunct tube as employed originally by Crookes.

Functionating tubes may be divided into "soft," "medium soft" and "hard." At either end of this scale are the tubes which are too soft, namely, contain too much air and do not allow of the transformation of the current into *x*-rays, and the tubes which are too hard, namely, contain too little air and cannot be penetrated by electrical currents at our present disposal.

The x-ray from the soft tube possesses but little penetrating power; its shadow picture presents "black bones"; its radiation is quickly and superficially absorbed by the tissue; it has slight therapeutic value.

The x-ray from the medium soft tube transforms most of the electrical energy imparted to it into x-ray energy; its shadow picture is sharply defined and the one most commonly desired and obtained; its radiation has a good penetrating power, though much of it is absorbed by the integument; it should therefore, be employed when we wish to produce an effect upon the skin.

The x-ray from the hard tube possesses the most highly penetrating power; its shadow picture presents comparatively little contrast though it does not lack in other signs of definition; its energy is not lost in superficial tissue, but is also expended upon the deeper tissues; it should therefore, be employed when we wish to affect the deeper parts of the body.

The sole point to weigh, I imagine, as to this entire question of vacuum is, at what part of the patient's body do we wish to have a transformation of x-ray energy into chemical energy. If in the integument, then we would use a medium soft tube; if deeper, a hard tube. Personally, I may say, I lean in my preference toward a hard tube in all my treatments.

5. *Effect of the Exposure.*—There is no evidence to justify the assumption of an idiosyncrasy on the part of the patient to dermatitis, ulceration, or necrosis. We should, however, keep in mind that the skin of the face and hands is more susceptible than that of other regions, that the mucous membrane is more sensitive to the ray than the skin, and that areas of existing inflammation are the most susceptible.

The general effect of an exposure is, as has been said, to produce, when carried to extremes, the common symptoms of inflammation. When not carried to extremes, or when used within other therapeutic limits, I suppose the effect to be due to a reaction in the vital tissue processes (metabolism) ascribable to having set up new chemical exchanges. If metabolism is the sum total of all the chemical exchanges which take place in a living animal organism; and if, secondly, the *x*-ray effect is a transformation of *x*-ray energy into chemical energy, then the conclusion seems inevitable that the effect of the *x*-ray in the cure of disease is due to a primary chemical reaction, affecting in turn the metabolic processes. How far the dissociation of the common atom and the molecule into the ion enters into this explanation, should be in time easily demonstrated. For my own part, I believe that scientific analogy points to the action of the *x*-ray as one of ionization. *X*-ray dermatitis and necrosis are too familiar to require description here.

I have noted two rather constant reactions in the treatment of cancer. The first, occurring in general carcinomatous infection, may be termed an early reaction period. In this the temperature may rise from 1 to 2° F., the pulse is increased in frequency, and the patient experiences "nervousness" and unrest and an increase of general fugitive pains. But the rule is an immediate cessation of pain, and within a few days the disappearance of small nodules, to be followed by the later reaction next referred to.

The late reaction is local and shows itself at any time in from one to three weeks, and seems to resemble in this respect the familiar effects of dermatitis. This reaction is in reality the first objective evidence of a retrogession of the new growth (carcinomatous or sarcomatous tumor). Illustrative of this point I quote the following:

Dr. C. B. Ferguson, President of the British Medical Association, reports a case of carcinoma of the manubrium of the sternum, involving a tumefaction and an open ulcer, where the patient received treatment daily, extending over a period of twenty days, and then ceased treatment, and went home, showing at the time but little evidence of improvement. After several months the patient returned and, to Dr. Ferguson's surprise, the ulcer and the tumor had entirely disappeared; the patient was cured.

Cases of failure to secure any improvement in sarcoma within eight or nine days have been reported. In all such cases the lateness of a possible reaction must be kept in mind.

6. *Time and Other Conditions of Exposure.*—The time of exposure depends primarily upon the intensity of the *x*-radiation. Our effort should be to standardize every step of treatment. If we use a coil, we must know the volts and amperes and number of interruptions per second; if a static machine, the number and diameter of the plates and the number of revolutions per minute. With these data, an established and constant quantity, we should adopt a standard intensity of *x*-radiation, a standard distance of the tube from the patient's skin, and a standard duration and frequency of application.

Instruments to measure fairly well intensity of penetration have already been devised, based upon Professor Röntgen's original suggestion, and we may soon be able to buy them.

Roughly speaking, I select a tube just beginning to be hard (corresponding to from five to seven inches spark-gap of the coil), giving a good photograhic picture of the hand in one minute at a distance of two feet, and equally clearly giving a good fluoroscopic outline of the skeleton of an average man at the same distance. I select a distance of eight inches and a duration of from six to eight minutes, and give it treatment three times a week. In this manner, where sound skin intervenes, I usually get a dermatitis of a mild type in from one to two weeks. This dermatitis I do not fear, but, on the contrary, anticipate producing. But now, instead of stopping treatment, I go right on (shifting the central focus of the tube however often) until I have converted a bright erythema into a brown and often, in brunettes, into a blackish "tan." The patient once properly "tanned," it is extraordinary how great an intensity of *x*-ray may be administered. In some of my patients whose skin is already tanned as black as a dark mulatto's, I am giving treatments of from eleven to fifteen minutes, three times a week, with no harm to the skin. I think the effect is exactly the one aimed at by the bare-backed and bare-armed oarsman, who systematically tans his body. Daily and short exexposures to the sun soon enable him to defy its hottest rays, whereas one single, first and long exposure would set up blisters and ulcerations and cripple him for weeks.

However, I wish here to distinctly put myself on record as refusing to advise anyone else to "tan" a patient with the *x*-ray. It is a process that each must judge for himself and decide accordingly. It is mainly, however, a question of systematic and standardized technique. It is commonly advised, I am well aware, to cease treatment as soon as dermatitis sets in, but for the reasons given above, I have discarded this advice. After the skin has been hardened, say at the end of two to three weeks, I give ten to fifteen minutes' treatment three times a week. In cases of internal cancer, it would be impossible to succeed unless we could continue in spite of the erythema and tan the patient as described. On the whole, as to frequency and intensity of treatment I would say, feel your way along the first two weeks; force your way the next two weeks and after. And, following this general advice, certain cases of exterior cancer, or interior cases, where the same area of skin is not necessarily constantly subjected to radiation, may be *x*-rayed more frequently, and even daily.

Finally, as a last word in regard to technique, I cannot protest too strongly against the submission of a patient to *x*-ray treatment by unskilled hands.

The outfit, like the surgeon's knife, is a simple one, but the outcome, in the hands of the immature operator, is as if the surgeon should turn over his scalpel to the nurse. It is the state of the vacuum and the consequent quality of the radiation produced, which is both the fickle and the dangerous feature of administration. At one moment with one tube a radiation flashes forth which cuts down animal tissue as does the hot wind of Sirocco cut down plant tissue life. At the next moment, or with another tube or vacuum, a deceptive ray glows to the eye at the fluoroscope, and yet has little or no effect upon the disease. There is always some danger, even in skilled hands, and likewise uncertainty enough, but, in unskilled hands, the danger is as unpleasant to contemplate as is the report of results obtained, valueless.

In such hands a negative result has no meaning, an affirmative result is an accident. It would be wise if a school of instruction for *x*-ray workers could be established.

II. Indications and Observations. — The *x*-ray worker, from his standpoint, may classify his cases naturally, according as they are: (1) Exterior; (2) Interior; (3) Operable; (4) Inoperable.

1. *Exterior.*—When the disease has involved the skin, or the skin has broken down, the case is exterior. When, on the other hand, healthy skin covers the new growth or other disease, the case is interior. The operable and inoperable classification explains itself.

In exterior cases, as for example, of epithelioma' papilloma, rodent ulcer, lupus, etc., the effect of the radiation may be closely watched. A shield protecting the sound skin is desirable, though I see no reason for insulating it.

In this class of cases the indications of experience thus far gained fully justify a resort to the *x*-ray in preference to any other treatment. True, a small and isolated epithelioma may sometimes be preferably cut out or scraped out or be treated by caustics, but, on the other hand, cases of large areas of destructive and advancing epitheliomas and lupus have already been reported in great number, where nothing yet known except the *x*-ray would have saved the patient from extensive surgical mutilation and possible death.

2. *Interior.*—In interior cases the operator's hands are tied, and his efforts are limited by the fear of breaking down the normal and intact integumental tissue. It is here that the "tanning" process may be resorted to, as, for instance, in osteosarcoma, and in carcinoma of the breast and other tumors either immediately or remotely underlying the skin. In these cases the high vacuum tube, with its deeply penetrating *x*-ray, is indicated.

And in these cases, I have no hesitation in claiming that the *x*-ray has an immediate and continuous effect of relief from pain and circumscription and retrogression of the disease. In a case of abdominal and inoperable sarcomatous tumor, closely watched by Dr. Leonard Weber, who kindly referred the case to me, the gnawing, constant pain ceased entirely within one week. By palpation the tumor is greatly reduced in size, and can now scarcely be felt, and, by fluoroscopic examination, is visibly reduced more than one-half in size.

In a similar case I am now treating, the pain ceased at once, and the patient can walk about and attend to business. In two cases of malignant growth at the pyloric orifice of the stomach, the pain has entirely ceased, and the patients can for the first time in months take solid food.

In two cases of epithelioma within the fauces, and necessitating treatment through the skin, the symptoms of burning and discomfort have ceased, the tumors are reducing in size and, to say the least, an advancing disease is arrested in its progress. The same statement applies equally to cancer of the rectum and of the uterus. Will these cases be cured? I frankly say I don't know. Their treatment has not yet extended over a sufficient period of time and it is, therefore, too early for me to venture an opinion.

In another class of "interior" cases, namely, carcinoma of the breast, the results thus far obtained are most hopeful. One recurrent carcinomatous tumor of the breast I have reported cured, and it remains cured to date. Three other cases of this type, not yet reported, exhibit now no tumors and no symptoms of cancer. They seem to be cured. Unfortunately, of a large number of such cases I am treating, all but one, just beginning treatment, are of long standing. Their behavior varies. In some of them the ulcerations have already healed with a clean cicatrization, scattered nodules hardened and reddened areas have softened and disappeared, indurated glands are no longer to be found, and pain, of course, disappeared very early.

In only one case has merely moderate progress been made in reduction of the size of the tumor. This tumor is of stony hardness, attached to the periosteum of the ribs, and of intense redness. The case is inoperable. This much, however, even in this case, has been gained. Previously, at each menstrual period the tumor increased at least one-fifth in size. Now, two periods have passed and the tumor is somewhat smaller, and certainly more movable.

I am, furthermore, treating a patient with appendicitis, who was suffering daily pain and advised to submit to an immediate operation, but who has presented no further symptoms of the disease from the first week of treatment, except one mild attack.

As a further instance of interior effect, I have treated and cured two patients with melancholia by *x*-raying the brain, and relieved a tic douloureux, which has undergone two operations to remove the nerves, by *x*-raying the casserian ganglion.

There is, therefore, no question in my mind, but that the *x*-ray should be employed in interior and in internal cancer and other diseases internally located.

3. *Operable Cases.*—In so-called operable cases of cancer, particularly those of carcinoma of the breast, the propriety of employing the *x*-ray will, no doubt, be long a debatable ground. For my own part, I now believe that no case should be operated upon until it has first been treated by the *x*-ray, and for these reasons:

(*a*) The earlier a case can be treated the more rapidly it yields to the influence of the *x*-ray.

(*b*) The infective process (distribution and growth of the cancer particles) often ceases under *x*-ray treatment; the proof of this assertion lies in the fact that this process, even when fully developed, may be arrested by the *x*-ray, and visible carcinomatous nodules and kernels disappear, while no new ones occur.

(*c*) Circumscription of the area of invading disease, retrogression of the growth, and relief from suffering can be confidently predicted.

(*d*) So long as a malignant growth continues to improve under *x*-ray treatment, no operation is necessary.

(*e*) Of the two, the *x*-ray and an operation, the former appeals to the patient as an infinitely preferable procedure, and should it fail no valuable time has been lost.

(*f*) A sufficient number of carcinomas of the breast, of sarcomas, and of epitheliomas cured have already been reported to justify a claim that the percentage of permanent recoveries may compare favorably with the results attained by a surgical operation.

And where infection (distribution of the disease) has once actually and visibly or palpably occurred, there is in my mind no shadow of doubt that the *x*-ray should be first employed. For, and it is an important reservation, a conceded percentage of recoveries after surgical operation for carcinoma of the breast is probably no more than 15 to 25 per cent. Indeed, Dr. R. Fitz of Boston is quoted as saying that the records of ten years in the United States show that seven out of every eight cases operated upon have recurred. Dr. Sands of this city is quoted by Dr. Abbe as even refusing during the last years of his life, from conscientious motives alone to operate any more upon the carcinomatous mamma. It should, however, be mentioned that some most excellent authorities claim a percentage of permanent recovery as high as 33⅓ per cent.

In view of this showing, and comparing it with what has thus far been accomplished by the *x*-ray in both carcinoma and sarcoma, we can at least contend that the *x*-ray is on even terms with an operation, and from the patient's point of view also, preferable to one.

In relation to the propriety of using *x*-ray before an operation, I can contribute an interesting observation. In a case of rapidly advancing epithelioma of the upper jaw a bright beef-red diffused coloration extended almost across the mucous membrane of the roof of the mouth. At the third treatment a clean line of demarcation appeared just to one side of the median line, presenting a characteristic serpentine edge. Here, clearly, the disease was circumscribed, and there can be no question that if operation should be deemed advisable, that this outline would be of the greatest assistance to the surgeon in making his work complete.

So, likewise, in all malignant tumors, their outlying areas contract in extent, and the tumors, so to speak, kernelize. They grow harder and smaller.

That the *x*-ray should be used after an operation would seem to me also a most justifiable conclusion. It can search out foci and areas of infection unreached by the knife and unsuspected by the operator.

The cases of carcinoma of the breast which I have found to be without exception the most susceptible to *x*-ray treatment are those of a recent recurrence after operation.

In one case a fresh recurrent nodule disappeared in three weeks. In two cases recently treated, referred to me by the surgeons who had operated upon the primary cancer, a recurrence took place in nine and four weeks respectively after the operation. The recurrent tumors were situated in the scar, and were about one and one-half inches broad by two long and fairly hard. These tumors disappeared within two weeks, leaving a thin and flexible line of scar tissue. In one of these cases there still existed a drainage opening with most foul odor. The odor at once ceased, and the drainage opening, distant, by the way, from the recurrent tumor, closed.

The above instances emphasize what all recognize, that the next important step in the x-radiation of cancer must be toward a proper selection of cases. For, not only do different kinds of cancer vary in their vulnerability to the x-ray, but also, even, phases of the same kind, vary.

Finally, under proper conditions of administration, the x-ray builds up tissue. The following case is instructive: I treated a young woman for an enlarged gland and gland inclusion in the right axilla. At the end of six weeks the lymphatics were comfortable, but the patient remarked, and it was plain to see, that the neck, chest, shoulder and breast on that side had remarkably developed, and that the skin on that side was firm and glossy. The patient now desires to receive treatment in the left axilla to even up matters.

In treating the brain in the two cases of melancholia which I have previously referred to, the hair became glossy and abundant and healthy where it had previously been dry and scant.

In fact, the question may, be reasonably asked whether the general therapeutic effects of x-radiation are not due to a capacity for establishing favorable tissue metamorphosis, rather than to a capacity for destroying or modifying bacteria or other microorganisms.

4. *Inoperable Cases.*—As to inoperable cases of cancer, there can be no discussion. There is but one simple axiom—so long as improvement continues, continue the treatment. It is here merely a question of a race between the x-ray and a fatal termination.

Conclusions.—1. Radiotherapy broadens our conceptions of the possibilities of the therapeutics of modern medical science.

2. The x-ray has a general application for the relief of pain.

3. As to technique, a standardization as to apparatus and its capacity, and as to duration and frequency of treatments and distance of the tube is recommended to operators.

4. The x-ray has a curative effect in internal cancer and other internal diseases.

5. For superficial diseases a medium soft tube may be used, for internal cases a hard tube. The hard tube is applicable, however, in all cases.

6. X-radiation is recommended prior to any operation, to clear the tissue of cancer particles and foci, and to circumscribe the disease.

7. X-radiation is recommended after operation to preclude a recurrence.

8. X-radiation may be recommended in place of an operation, and may be preferable to one for the reason that operation secures but a comparatively moderate percentage of permanent recoveries, and because up to date the x-ray procedure shows a continued improvement in cases, and a percentage of cures which will, undoubtedly, compare favorably with surgical operations.

9. There is danger to the patient or uncertainty as to what might be accomplished when the x-ray is employed by immature operators.

10. In x-radiation we possess more nearly a solution of the problem of curing cancer than by any other method of treatment.

BENIGN TUMORS COMPLICATING PREGNANCY.

By BACHE M. E. EMMET, M.D.,
NEW YORK.

This subject is a larger one to consider and discuss than might appear at first sight, for, commonly, our mind is prone to dwell mainly upon uterine fibromyomata on account of their relative frequency as a complication. But such tumors fall far short of representing the total number which may occur and act in this wise.

When we look over the field, only to mention those of benign character, we find that there is not a single organ in the pelvis, nor scarcely in the abdomen, which does not, upon occasion, yield a tumor which may complicate pregnancy.

Though I shall not seek to enumerate all, certainly not to dwell upon them individually at length, yet may I bring to your attention for a few moments such as shall be of more than passing interest.

To take up, first, the possible tumors of the abdomen. Passing over tympanites, we have ascites, which may be due to a disease of the liver, heart or kidneys, or to a diseased peritoneum. The accumulation may reach such a degree that it shall prove a most uncomfortable complication, not only in the way of pressure upon the developing uterus and of pressure downwards upon the enlarging veins and softening vagina, but, also, by pressure upwards of the intestines against the diaphragm, producing dyspnœa, both by displacing this muscle and by compressing the lungs into a limited space.

Apart from these effects, the added size to a pregnant woman makes her difficulty of locomotion pronounced; hence such a complication may well call for treatment by evacuation by one means or another to minimize the suffering which it induces.

Hydatids may also produce a like tumefaction and discomfort.

An enlarged spleen has been known to drop so low in the abdominal cavity as to seriously inconvenience a pregnant woman. We may strive to replace and hold it in proper position. Fortunately, cysts of the spleen are rare, but we find an occasional paludal example. In such a case, should we consider that quinine might prove a beneficial agent for its reduction in volume, we are at once met by the objection that this drug is a first-class abortifacient, and, therefor, the discomfort must be endured throughout pregnancy, possibly to the marked detriment of the woman's health, considering what is the rôle of the spleen in the normal state; or it may even become necessary to bring about a miscarriage.

A kidney which may already have been displaced, it may be cystic and possibly adherent, is certainly not prone to assume a better position because of an established pregnancy. I know of no observations by which to estimate its conduct under such circumstances, but, with the chance of the vessels and ureter being pressed upon by an enlarging uterus, which circumstance so frequently leads to the presence of albumin in the urine, even leaving out of consideration the tendency to hyperæmia which may be established by the pregnancy, we may confidently assume that a displaced kidney will become very considerably increased in volume and present a most unpleasant complication.

Add to such consideration the fact that a nephroptosis is already productive of very positive reflex symptoms upon the stomach, and we have at hand a factor which may do much toward establishing incoercible vomiting. It may be that this condithat has been noted as a concomitant of that most terrible affection, I have never heard it mentioned, but I think we may recognize that as a reflex agent and in the way of inducing hyperemia, nephritis, and albuminuria we have in such a tumor a very decided and serious complication of pregnancy.

Any attempt made to replace and maintain this organ or perhaps the two in position will under these circumstances probably prove futile.

It seems, therefore, as if such a condition might entail a most troublesome and tedious course of the pregnancy and necessitate maintaining the woman in the recumbent posture with hips raised, if not even the production of abortion or premature labor.

Excessive distention of the bladder, either as a neurosis or due to forcible ascent of a pregnant uterus owing either to lack of space in the pelvis (deformities) or the presence of tumors, or again from pendulous belly, in which case the uterus may hang over the pubes, is not an unknown occurrence.

Cystocele in women who have borne a great number of children has at times proven a most troublesome complication. Protruding from the vulva, such a sac has at the time of labor even been mistaken for the membranes, and has been opened up to allow the liquor amnii to escape. In another instance, by reason of its thin wall and because it contained fluid, it was mistaken for a hydrocephalic presentation and punctured. Such a bulging of the neck of the bladder and the anterior portion of the base may occur, even though the woman appear to pass her water regularly, yet I cannot think that a careful physician could misinterpret the appearances nor allow such a hernia to persist. Yet these unfortunate circumstances do happen, probably to women who have no proper advisers.

A stone in the bladder has been known to form a most objectionable tumor, sometimes encroaching upon the caliber of the pelvic canal. As the time for labor approaches it may be carried forward by the pressure of the head and prove a positive obstacle to delivery. We can the better understand the possibilities of a complication of this character if we realize that such calculi may be of any size. I have seen one as large as an ordinary orange, which would most surely have established an insuperable barrier; and those of smaller size may also become imprisoned in the lower segment of the bladder in vaginal cystocele, giving great pain and blocking the way.

Smellie reports such a case, of which he says, "a calculus of large size" worked its way out through the base of the bladder. This admitted of the immediate passage of the child. A midwife was in attendance. There must have been a terrible vesical catarrh antedating the pregnancy and distress of the bladder sufficient to call for medical care were it at hand; it is even wonderful that such a sufferer could allow coitus to take place.

The care of the bladder during pregnancy cannot be too urgently insisted upon, both on its own account and in view of the approaching labor.

As already said, some women will seemingly empty their bladder, and yet, in one instance, it may still be overdistended—"ischuria paradoxa"—or in another, like cystocele, a certain small portion may be retained, which will undergo deterioration, even putrefaction. The bladder may be adherent to a fibroid or to an ovarian or parovarian tumor, and cannot, therefore, contract fully to empty itself, and thus becomes an innocent party to a possible overdistention. Exploration with a sound will reveal either condition as well as the possible presence of a polypus or a stone.

The question of ultimate treatment under like conditions might lead us too far in this paper; methods for mediate relief will, however, quickly suggest themselves, seeing that the bladder may be emptied in either case. Should we find a foreign body of any type in the bladder, we may proceed to remove it at once if it threatens to prove a troublesome complication—of course, in the case of the bladder being attached to any tumor, the question of the tumor itself being removed will be involved. This will be considered later on. I mentioned vaginal enterocele above. Such a condition has been noted as a complication of pregnancy in quite a fair number of cases. One observer collected as many as twenty-seven. This is surely of sufficient frequency to have the possibility of its occurrence in mind. These cases have been due mostly to an injury of the posterior wall of the vagina, a separation of the muscular fibers, brought about by contusion in antecedent pregnancies. This, with considerable pressure from above, allowed the gut, possibly the omentum as well, to protrude.

In others, the vagina had been injured in a similar manner on its lateral or anterior aspect.

I fancy that it is fair to assume that a general relaxed condition of all supporting parts was also, in a measure, the cause, facilitating an enteroptosis.

Such a complication may prove exceedingly distressing and difficult to manage, no doubt requiring the continued use of vaginal tampons, and possibly calling for complete inactivity on the part of the patient.

When the omentum descends along with the gut we realize that quite a tumor is formed. Such a one has protruded even at the perineum, forcing down Douglas's pouch behind the vagina to that extent.

A similar tumor has formed in the labium of one side or the other, the bowel escaping along the Canal of Nuck.

They may prove very difficult of diagnosis, especially where the omentum accompanies the gut or descends alone.

Fortunately the treatment of such cases is all of one kind, replace and maintain in position.

As a matter of curiosity, I may mention that the gravid uterus has itself been found in the inguinal canal, forming a tumor which quite reached to between the patient's thighs. It has also developed upon the abdomen after passing through the linea alba.

In the way of other hernias, viz., inguinal and crural, many are recorded which, under peculiarly favoring conditions, have reached to dimensions to be called tumors, especially when the patient has not been under the observation of a physician.

An abscess of the gland of Bartholini has shown itself of enormous size, really a tumor, and there have been other large, solid and cystic tumors of various kinds found within the vagina and at the vulva, which, though complicating pregnancy, presented their worst features at the time when labor set in.

One author is quoted in the "American Textbook of Obstetrics" as having collected sixty such cases; among them were twenty-three cysts and echinococcus sacs. I may mention another; an hæmatoma, perhaps a rare occurrence, yet of considerable importance, as it has been known to be caused by the rupture of an artery during the late months of pregnancy. Usually, of course, one vein, or several, which have been varicose from earlier pregnancies are the vessels at fault, but in the case of an artery giving way even before labor sets in, we can well see what are the possibilities of a tumor forming in the cellular tissue, even causing death before the exact state of things may be recognized; at all times giving much annoyance by pressure both to the rectum and to the bladder.

Of sixty-two such cases, which were reported in one instance, "the mother succumbed in twenty-two, and, with the exception of a single case, the children in those twenty-two cases were lost."

Hardened fæces in the descending colon, sigmoid flexure and in the rectum, form occasionally in one portion or the other a tumor of such volume and comparative immobility that it gives rise to much surmise and no little discomfort. Such a mass is sometimes side-tracked in a pouch, and allows of other fæces passing by it or even through it. The mass may attain to a very great size and one may have to scoop it out, after flushing the bowel repeatedly with hot water and inspissated ox-gall or crude kerosene, and giving salines or castor oil by the mouth to soften it and bring it down within reach.

I at one time knew a family in which the habit was established of defecating only once a month, when the menses appeared. Such had been the habit, I was told, of grandmother, daughter and granddaughter. It is not difficult to imagine a fæcal tumor forming a complication of pregnancy in one of that family.

Polypi growing from the uterine canal are not at all uncommon, either within the canal or hanging in the vagina. A mass of this kind may become a great annoyance during pregnancy, as well as prove a very threatening complication to labor. Such tumors can readily be disposed of at any time; should the woman, however, not be under observation, there is every reason to fear an abortion or an early miscarriage from its presence, not to speak of its being such a common factor in dystocia.

There is one class of growths which I shall scarcely more than bring to your notice for the purpose of rounding out somewhat my presentation of complications of this character. I allude to exostoses about the pelvis and to diseases of the vertebræ, giving rise also to deformities which assume the type of tumor. The first may form a prominence upon the promontory of the sacrum, which may diminish the caliber of the superior strait, crowding the pregnant uterus, so that it may hang over the pubes, or such a growth may form upon the symphysis pubes; one as large as an egg has been noted. Then there is the spondylolisthetic condition, in which the last lumbar vertebra may slip down upon the first sacral; it has been known to almost turn face downward, and the two bones have been found united by bony callus. Such an occurrence allows of the vertebræ immediately above dropping also—indeed, they must of necessity, once this prop is removed—this condition is called lordosis, and the bones project very positively into the pelvic cavity, forming properly a bony tumor, usurping the space necessary to a pregnant uterus, possibly displacing the organ backwards in its early development.

A fracture of the sacrum may produce a like deformity, the whole pelvis tipping forward, thus again making the promontory project markedly.

I shall only casually mention that form of exostosis giving rise to the name "pelvis spinosa" on account of the sharp edges or rims assumed by the osseous formation which projects into the pelvis, more especially at the pubo-iliac junction. These have been known to perforate and lacerate a pregnant uterus.

Cystic ovarian tumors form a very frequent complication of pregnancy. Though it may be held as an uncommon occurrence that pregnancy should exist when both ovaries are diseased, yet it is not unknown and, of course, the complication is greater than in the case of only one being involved, both from the fact that there is a two-fold cause of impaired health, and, further, that the chances of mechanical interference with pregnancy and labor are multiplied. Ovarian cystomata may further complicate a pregnancy by establishing adhesions, and they may prove as difficult to displace as a cyst of the broad ligament or any other retroperitoneal neoplasm. Such growths may also assume various changes in structure, and thus present still further complications.

Some surgeons might decide to leave such tumors during the term of pregnancy and deal with them after labor, inasmuch as they generally rise high in the abdomen and may not crowd the uterus. It may be, however, that one has attained such a growth that the patient will undoubtedly experience great discomfort as pregnancy advances. In past times such a tumor has been tapped, the surgeon holding himself in readiness to operate immediately should any unfavorable symptom develop; to-day, if pregnancy is still in the early months or, again, if it has attained the later months, a laparotomy may and should be performed, with perfect confidence that it will not interfere with gestation in the least. Occasionally, a cyst will drop down behind the uterus, and so worry this organ that one may fear an abortion. One may then be led to tap it, especially if one finds it late, or one may remove it per vaginam; still, even ovarian tumors and dermoids adherent in Douglas's pouch have been removed in the eight and ninth month. In one case the uterus was turned out upon the abdomen for the purpose, and gestation went on to full term without accident.

Most all other tumors of the adnexa, dermoids, fibroids and cysts, if they remain well up in the abdomen, may prove harmless to the pregnancy and may be ignored. If they develop, however, to an excessive size, but, particularly, if they fall into the pelvis and cannot be so raised and displaced that they shall remain above the brim, they must be dealt with by operation, to prevent abortion or dystocia.

Pus-tubes cannot be raised, and are, at all times, in the way; one cannot ignore their presence. As soon as they are recognized they should be removed, otherwise they may be crushed as pregnancy advances or during labor by the child's head, with the immediate result of acute peritonitis.

Fibromyomata and myomata form, perhaps, the most frequent tumor complications of pregnancy with which we have to deal. They are generally multiple, and may be situated in any part of the organ—the body, the lower segment, or the neck. They may be submucous, interstitial, or subperitoneal; these and the submucous may be sessile or pedunculated, and a pedicle may be of such length that a tumor, or a portion of it, may be quite considerably displaced from its base.

Such tumors constitute a serious complication of pregnancy from the very first, in that their presence frequently breaks up the regularity of menstruation, so that patient and physician may be very much at a loss to know when pregnancy has begun. A cessation of an habitual hemorrhagic condition may simulate a missed menstruation;

again pregnancy may really have set in and we may overlook it by attributing the occurrence of a [illegible] due to a fibroma. Even if a woman who is known to have fibroids becomes pregnant, the increase of volume of the uterus may bear two interpretations. The difficulty may be as great if we have not known of a prior fibroma; recognizing such a tumor, one may not know but that there is also a pregnancy.

Again, one may appreciate pregnancy and overlook a fibroid. Of course, in the latter months such points may be cleared up. Auscultation may be much interfered with by the presence of fibromata; still if the heart-beats are once heard, a positive diagnostic point is established.

Then touch and palpation serve also for the later months, although if a fibroma be on the posterior face of the uterus or interstitial or submucous, error is still possible, or it may never be recognized at all. Another curious instance of error is that in which the entire development of pregnancy took place in the cervix, and the uterus from the internal os up, formed a tumor upon this mass and was mistaken for a small fibroid.

There was, however, also found in this case a real fibroma on the inside of the cervix, flattened and projecting into the vagina, where it blocked the way and prevented delivery.

An immense tumor at the junction of the neck and body, interstitial and yet submucous, was not recognized at all, yet it prevented the dilatation of the neck and absolutely prevented the head engaging. The woman died undelivered.

In spite of these many possibilities, we must admit that pregnancy frequently progresses normally and reaches its term without any mishaps. Especially will this be the case if the fibromata are subperitoneal, are in the body of the uterus, if they are not numerous, are not large, and do not grow rapidly. Per contra, if we have large fibroids, the patient will probably suffer severe abdominal pains, she will be much encumbered by their weight, and it will be difficult for her to get about. By pressure they may produce ascites and albuminuria, or the uterus may be retroverted. Furthermore they may themselves break down and poison the patient. The interstitial and the submucous may cause a faulty implantation of the placenta, and they are constant menaces of hemorrhage and abortion.

But it is to those developing within the pelvis, those in the lower segment of the uterus and about the neck that we must look for the worst symptoms and the most troublesome complications of pregnancy. By their increasing size they interfere with neighboring organs, just as we have seen that other growths are harmful. By annoying the bladder, they produce dysuria; by compressing the ureter, they may cause pyelitis or hydronephrosis; they favor constipation and provoke cramps in the legs and neuralgia by pressing upon the sacral nerves; they may also be the cause of death of the fetus; this may mean putrefaction and the subsequent death of the mother. Finally, fibromata may be the cause of faulty presentations, such are said to be common.

Now, for a moment before closing, we should consider the manner of dealing with this complication.

It is evident from what has been said above, that the question of differential diagnosis is an all-important one, and next in importance is the correct estimate of the possible evil influence of fibromata during each pregnancy.

The limitations of this paper or time limit will not allow me to enter upon a discursive study of these two most interesting subjects, each one of which is worthy of a prolonged discussion, so my remarks will be confined to setting forth my condensed views upon the subject of when to interfere and when not to interfere.

From what has gone before it may be inferred, and correctly, that I would willingly operate on all young women non-pregnant who may expect to become so at any time, and remove any fibroid of the uterus which is accessible. Should the young woman be recently pregnant, I would remove such growths if it be large, wherever situated. If it has grown slowly and is small, I should leave it if in the body, but remove it if in the lower segment or neck. If the patient be midway in pregnancy, and such growths be discovered, I should leave them alone absolutely, if they are in the body and not giving rise to trouble. If in the lower segment or neck, I should temporize, seeking to crowd them out of the pelvis and try to tide over until the uterus has become thoroughly accustomed to the pregnancy, when I might still hesitate about interfering at all, but watch and choose my method at the time of labor; possibly no interference may be necessary, or it may prove desirable before that time to induce premature labor. Should such growths be discovered only in the late months, I would operate only if they grow in the neck and of such size—egg or larger—as to threaten to impede delivery. Then I should operate from below. However, even then, I might decide to await events at time of labor, or induce a premature birth. But tumors may be so general and threatening that one is obliged to remove the whole uterus, even early in pregnancy; I have reported such a case, and with all our desire to be progressive, yet conservative, we may still be driven to Cæsarean section or to the Porro operation.

18 EAST THIRTIETH STREET.

MALIGNANCY COMPLICATING THE PREGNANT STATE.*

BY S. MARX, M.D.,
NEW YORK.

THE individual experience of any operator dealing exclusively with the subject which your chairman has selected for me must, of necessity, be very limited. And this for several reasons. Malignancy is a condition of advanced life, and is very seldom found during the procreative period. We except, of course, in this statement the other forms of malignant growths, such as sarcomata, which are growths of younger life. All malignant tumors of the genitalis, except those of the uterus, seem distinctly to prevent the possibility of conception. For the reason that in malignancy, attacking the appendages destroys the life-yielding element furnished by the ovary and transmitted by the oviducts, and thus inhibits, if not absolutely prevents, the male and female products coming together. But where the cervix uteri, or even the body of the organ, is attacked by a malignant tumor during the period of possible fecundity, there is from my individual experience a greater possibility of impregnation than under normal conditions. This, I believe, is due to the increased succulence from an increased blood supply to the parts, making their receptive conditions decidedly a favorable one for the lodgment of the impregnated ovum. Whether the ova under these conditions are as successfully carried to term, is another question, and not within the line of discussion. Clinically, this is proven by the large number of cases reported in which pregnancy is associated with malignant tumors, especially carcinoma of the cervix. Consequently, this subject becomes one of the greatest importance, in view of diagnosis, prognosis, and especially treatment. The very fact that the condition is a rare one, generally speaking, makes it all the more important that its possibility should ever be borne in mind, and a differential diagnosis must always, if possible, be made, not alone against, but in favor of, malignancy. This is readily done by exclusion, by direct examination, or by the excision of a piece of the suspected part for a microscopic examination, even at the expense of terminating the pregnancy. If there be no visible sign of malignancy, and the suspicious bleeding or a foul odor persists, and a diagnosis by exclusion is impossible, one is certainly warranted in emptying the uterus in the interest of the woman. I hold here, as elsewhere, that hemorrhage is inconsistent with normal pregnancy, and a woman who bleeds presents a pathologic condition, for some reason or other, and, as such, requires not tentative but active treatment. An instructive case is the following one in which a diagnosis of beginning carcinoma was made by two very able physicians in a woman pregnant eight months: This error was made because the patient presented a badly eroded os, and she bled very profusely. A careful examination showed the patient had a very low placental implantation, and that the hemorrhage came from this and not from the supposed cancer of the cervix. Labor was induced and the woman made a normal recovery. It is now two years, and the patient is fully recovered. This error in diagnosis is excusable, since it must be remembered that the disease is very rare, occurring in less than ½ per cent. of all cases of cancer in the female. There is only one way of making a diagnosis, and that not always a positive one. This is by exclusion.

---

*Read before the Section of Gynecology and Obstetrics, New York Academy of Medicine, April 24, 1902.

A direct visual examination is the only method we have to clear up the diagnosis as between malignant conditions of the cervix and other lesions causing persistent hemorrhage: as an eroded cervix, varicosities, and so forth. Direct examination or local findings will, in all probability, give us the clew as to the presence of a vicious implantation of the placenta, a condition which will very often simulate a possible cancerous state. If neither a microscopic or macrocopic result can clear up the condition to our absolute satisfaction, we are justified in provoking an abortion. This is advocated not alone for the purpose of making a diagnosis, but for the sole object in view in order to rid the mother of an unknown danger, the life of the child not being taken into consideration at all, since in all these cases the danger to the fœtus is especially great; for either the woman aborts or, if she should go to term, or at least live, the chances for the fœtus are small, for over 40 per cent. of the children are born dead. But, independent of this factor, it is absolutely essential for the future welfare of the mother, that an early diagnosis be made, and often, without the help of a preliminary emptying of the uterus, this is utterly impossible. If we are to help these patients to a successful termination, it is certainly necessary to operate early, and in order to do this timely and safely, an early diagnosis must be made. Thus it is advocated that, if in any case this cannot be done, it would be far more advisable to be sure, even at the expense of terminating the pregnancy, than to flounder around in total obscurity until safe and timely operating is out of the question. The plea for an early diagnosis of carcinoma holds good under these conditions, even as it is essential in cases where no pregnancy exists. We might say it is probably even more urgent to diagnose carcinoma during pregnancy than under ordinary conditions, for the stimulus which the uterus obtains from the presence of a fecundated ovum, causing a greater congestion and a more rapid growth of the lymphatics, will, we surmise, be an important factor in the rapidity of the growth of a malignant tumor during pregnancy.

The most important subject to be considered relates to the treatment of the subject under discussion. For practical purposes, we naturally divide the cases into those that are operable and those that are inoperable. For, while in the former, our duty lies solely in the interests of the mother, in the latter ones—the inoperable cases—we exercise our energies in the interest of the fœtus, since nothing of a curative measure can possibly give us the slightest hope of staying the lethal termination. Once a diagnosis of carcinoma is made, and a successful issue is to be premised, the uterus must be emptied by any measure that serves the mother the best chances. The child cannot be seriously taken into consideration, for in the cases discovered early the period of viability has as yet not been reached. What means we have at our command must always vary with the individual experience of the operator. He must choose between (*a*) terminating the pregnancy, and in a few days extirpate the offending organ; (*b*) To do both operations at one sitting, namely, to empty the uterus and extirpate the organ. There are a variety of ways in which this can be done: (1) Empty the uterus by the ordinary method, or, in the advanced cases of pregnancy, those at or near term, doing the so-called vaginal Cæsarian section; (2) This is followed by the removal of the organ by the vaginal route. It is remarkable how simple it is to do a vaginal hysterectomy, even in the case of a uterus at term after that organ has been emptied of the fœtus. The method of operating is as follows: The diseased parts are thoroughly destroyed by the cautery. The vaginal portion is then circumcised, and the bladder and rectum are dissected off. Both the uterine arteries are then secured and the uterus is split up to the point of separation into four parts. This at once dilates the entire cervix uteri and the lower uterine segment. The child is delivered by version or forceps, if it is viable, or a total embryotomy is done, if that period has not been reached. This is followed by the total removal of the cancerous organ; (3) Empty the uterus by the usual route and then attack the organ by doing an abdominal extirpation; (4) The performance of a classical Cæsarian section, especially if the woman be near the end of pregnancy, followed by a total abdominal hysterectomy. This last method is one that appeals to all, and seems to be the ideal and the favorite one in cases at term. There can be doubt as to its feasibility, but the great danger ever remains as to the possible infection of the peritoneal cavity, if the operation is done as is usually described. To overcome this danger we wish to add a slight modification. After thoroughly cauterizing, if at all possible, the ulcerating area, we pack the lower zone tightly with iodoform gauze, and whip this over and retain the gauze within the cervix by a running suture so as to occlude the uterine cavity. The abdomen is then opened, the child removed, and a typical total hysterectomy is done. There is no doubt that in the earlier cases the ideal method is the vaginal route, preceded by a vaginal Cæsarian section, for it has appealed to us as the simplest and safest for the selected cases, possibly even advisable in cases at term.

For those tumors that are discovered too late to cannot obtain a radical cure by any operation, there remains but one factor to be taken into consideration, and that the unborn child. We usually tell the woman to term and make her as comfortable as possible by the liberal administration of opiates, and wait until the end of pregnancy, or until she goes into labor. Then we elect the only operation that appeals to us, namely, a deliberate Cæsarean section. Not that we care particularly for the interests of the mother, but as many of these women suffer from uterine rupture (over 40 per cent.) during labor, that the life of the child may be sacrificed because of this rupture. We wish to avoid this in order to bend all our energies in saving the child, for the mother's existence is of such minor importance under the conditions presented.

Occasionally, there is presented for our consideration a patient who is the victim of a malignant growth in some distant organ not connected with those of procreation and that patient pregnant at the same time. Generally speaking, there is no indication for us to interfere in these cases. Except that we are to deal directly with the advice to remove the tumor, if removable, we can do nothing except we feel that the pregnancy is an associate evil factor in the case. Then it behooves us to terminate the gestation. This indication becomes urgent, mainly in the interest of the child, while, occasionally, we interfere in order to overcome dangerous symptoms due to the pregnancy which would, in all probability, cause the mother's death in a short time, unless this interference were instituted. Such emergencies happened in two cases coming under my personal consideration.

A sixth multipara. Labors and pregnancies always normal. At the second month of the present pregnancy a small pigmented nævus was removed from the back, because of the annoyance it entailed and because it started to increase in size. She was then well until the sixth month of pregnancy, when she noted that the abdomen was growing rapidly in size. There was no reason for this, and it was thought due to a mild hydramnios. Urine normal. The distention now increases so rapidly that in two weeks it is enormous. The patient has now circulatory disturbances, cyanosis, and marked dyspnœa on exertion. There is no vomiting and no pain, and in other respects she is in good condition. The urine is markedly diminished in amount. In a short time, when I am invited to see the case, the abdomen was enormously distended up to the ensiform and the skin was tense and drawn and shiny. There was a distinct wave of fluid, and the percussion note varied with the position of the patient; in other words, a hydroperitoneum. No fœtal parts to be felt. Urine diminished in amount and the urea estimation shows only 9 grams in twenty-four hours. In view of the general symptoms, denoting a severe toxæmia, and the uncertainty of the complicating condition, it was thought advisable to induce labor. This was done by the cervical tampon, and in eight hours the fœtus was born. The abdomen did not collapse and the possibility of a twin pregnancy arose. I again saw the case and certified that the uterus was empty. The distension was found due to a peritoneal ascites. To account for this the patient was now carefully examined. At the ensiform cartilage a broad elongated rounded tumor was found which was movable and of semi-solid consistency. From the evident disturbance in the portal circulation, and the position of the tumor, and the rapid development of the ascites, our diagnosis was inclined to a malignant growth of the gall-bladder or the left lobe of the liver. This was confirmed a few weeks later by an exploratory section.

In this case, certainly a typical case for interference, even though the pregnancy were uncomplicated, we felt justified in terminating the labor solely in the interests of the mother, not alone for therapeutic purposes, but in order to clear up the diagnosis. This we certainly did without any material sacrifice, and at the same time rendering the closing days of the poor woman free from suffering.

The second case referred to our service from the neurological wards with a diagnosis of glio-sarcoma of the brain. The young woman was about eight months pregnant. We received her completely unconscious and with some evidence of beginning labor. Child alive and in good condition. With only an attempt at a narcosis, we got rid of the vaginal portion of the uterus by manual dilatation and then performed the classic vaginal Cæsarian section, and, by version, rapidly delivered a living child. The patient succumbed to her malady in twenty-four hours, and the autopsy revealed the correctness of the diagnosis.

In this case we acted solely in the interests of the child, for the mother's condition was utterly hopeless, and she was in danger of death at any moment. To anticipate this, we followed our invariable rule to act in that direction where we could do the most good. In this case, in the interests of the child, and in the former recited case, in the interest of the mother. There are a number of other conditions, due to tumors complicating pregnancy, which grow so rapidly and cause so much distress and danger, that, while not strictly malignant ones histologically, yet clinically simulate them so much so as to deserve the name pseudo-malignant growths. Witness, for instance, the rapidity of the growth of certain uterine fibroids in pregnancy which cause such grave disturbances as to preclude the possibility of a woman going to term. Here we are again justified to provoke labor in the interest of the child, of course always postponing such measures, if possible, until the time of fœtal viability. Unless the patient cannot be delivered except by an abdominal operation, we believe it far wiser to induce labor when the indication presents itself, and then at some time in the near future when the patient is not pregnant, to anticipate the recurrence of these growths by the removal of the now very much smaller tumors. Malignant tumors of the appendages, as a rule, are bilateral, and cause such destruction of the ovaries that pregnancy is the very rarest possible condition. But should pregnancy nevertheless occur, it becomes necessary to adopt a waiting policy until that time when we are called upon to interfere either in the interests of the mother or the child. A final topic now comes for our consideration, and while not strictly within the limitations of this paper, yet we feel that we are justified in calling attention to the so-called deciduoma malignum in an article devoted to the malignant growths occuring during pregnancy. We do this for the reason that it is our individual opinion that this affliction occurs, or at least begins, its inroads early in pregnancy, and is the cause of the abortion and the other abnormal conditions which are invariably associated with it, such as cystic degeneration of the chorian, and not due to the results of the abnormal changes in the products of conception. On this subject we can go no further, except to state from our investigations and clinical experience and theoretical knowledge, based upon careful perusal of the many cases now on record, that the chorioma malignum originates solely from fœtal structures, and the strongest proofs that we have rest in the fact that the condition is always dependent upon, and closely associated with, the pregnant state.

947 Madison Avenue.

UTERINE DISPLACEMENTS COMPLICATING PREGNANCY.*

By EDWARD A. AYERS, M.D.,
NEW YORK.

The subject of uterine displacements complicating pregnancy seems to best permit of classification according to cause rather than variety, and, while this cannot be accomplished succinctly, I offer the following as fairly satisfactory:

Displacements Due to Uterine Sources.—Retroversion and flexion, anteflexion and anteversion, prolapsus, incarceration.

Adhesions.—To bladder, to rectum, to abdomen (ventrofixation, suspensio uteri), to broad ligament, and to intestines.

Periuterine Pressure.—Pelvic abscess, appendicitic abscess, ovarian tumors and cysts, hernia uteri, hernia intestinalis, kidney (floating, sarcoma), bladder (urinary distention), extrauterine pregnancy, myomata, intestinal distention.

Retroversion.—The most important bearing of this displacement in pregnancy is the liability of the latter's ending in abortion or miscarriage. The uterine circulation is usually congested and slow moving, causing plethoric and asphyxiating conditions, which are prone to provoke either choriodecidual apoplexy or cellular disintegration—endometritis decidualis gravidarum. Endometritis and subinvolution are usually involved in the original causes of the displacement. The only treatment admissible after impregnation is support of the fundus with a pessary, regulation of the bowels, and avoidance of the erect posture as much as possible until the uterus begins to rise in the pelvis in the fourth month. Most cases do better without any local treatment.

Retroflexion.—Retroflexion is usually produced during subinvolution after pregnancy at full term by intestinal pressure on the fundus. Its most serious liability, aside from abortion, is to result in uneven expansion of the uterus, producing a double-pouched condition. The anterior wall expands ahead of the posterior, with the fundus somewhat at a standstill. The fetal head may thus be impacted in the lower pouch. Upward displacement of the head, even the entire change of its position, will best relieve the irregularity in uterine shape and growth.

Prolapsus Uteri.—Marked hypertrophy of the cervix may be mistaken for procidentia. Almost every grade of prolapse of the pregnant womb has been reported, although no case of complete extravaginal prolapse has, I believe, been reported as going to full term. Abortion has always resulted. In endeavoring to prevent abortion we should aim to obtain space above the pelvis through light diet and free bowel action, avoid the evils of gravity by having the patient remain recumbent most of the time, as needed, during the first four months of pregnancy, and assist the uterus to rise, if necessary, by the use of pessaries. Inflated soft rubber rings are the best for this. It must always be remembered that, in long existing prolapsus it is not feasible to push the uterus up, adhesions having developed with shortening of the ligaments. Spontaneous abortion will then usually occur.

Incarceration.—Fixation of the fundus beneath the promontory is a possible, and may be a serious consequence of retroflexion in pregnancy. It may occur without inflammatory condition, especially in extreme retroflexion. The fundus lies in the hollow of the sacrum, and the cervix is pressed against the bladder. So extreme may the displacement become as to threaten a fatal result. With sufficient enlargement of the uterus to fill the pelvis snugly, the bladder becomes unable to empty itself, the rectum has great difficulty in doing so, and, in addition to grave cystitis and constipation, emptying of the uterus in abortion may be impossible without operation. Pernicious vomiting may be caused by incarceration.

Should adhesion of the uterus occur in this position, there may be other resource than to induce abortion; but efforts should always be made by taxis to replace the organ. Such efforts should be preceded by catheterization, which will sometimes render replacement easy. Should catheterization be impossible, direct puncture of the bladder above the pubes should be employed.

Martin has seen 121 incarcerations in 24,000 patients. Symptoms do not usually appear before the tenth week. Severe cases cause bulging of the perineum. Unusual difficulty in micturition should awaken suspicion and lead to examination. Storer has rightly stated that cases of pregnancy in a retroverted uterus are more difficult than retroversion in a pregnant uterus.

Taxis for several days, at intervals, rubber bags filled with shot, laparotomy, Cæsarian section, Porro's operation, and symphysiotomy have all been done for this condition.

Class II.—Adhesions.—The uterus may become adherent to the bladder as far as the top of the fundus through ordinary sources of such adhesions or traumatisms in previous labors or gynecological work. I have met with such cases in abdominal work, and in one in pregnancy, in which the bladder was pulled upwards by the ascending uterus until it measured 10½ inches from the meatus. Separation then occurred spontaneously. Generally the bladder will be the only organ affected, though the uterus may be anteverted and later anteflexed. These cases are usually best let alone, as gradual elevation of the uterus gives the best taxis possible.

Adhesions to the Intestines.—Aside from displacements due to adhesions of the rectum and lower portion of the sigmoid flexure, which may cause retroversion, or retrolateral flexion during the first four months, adhesions of the uterus to the intestines rarely affect the normal elevation of the uterus, or its progress to normal labor. I am unable to state whether rupture of the intestines from adherent uteri have occurred, although it would seem that such accidents must have taken place. Should symptoms of such danger appear, such as severe colic with inability to secure movement of the bowels, the induction of labor would be indicated.

Ventrofixation and Suspensio Uteri.—When the operations that were devised to take the place of Alexander's method for supporting the non-pregnant uterus were first undertaken there was little, if any, regard given to the future obstetric possibilities. The consequence has been that many cases of pregnancy ended badly, a number of fetal lives being sacrificed. A Lapthorn Smith (Pregnancy Following Ventrofixation." Transactions of the American Gynecological Society, Vol. 23, 1898), was among the first to strongly emphasize the need of discrimination in method employed where the woman was liable to become pregnant. He reported thirty-six cases out of one hundred and forty-

---

*Read before the Obstetric Section of the Academy of Medicine, April 24, 1902.

[illegible] operations in which adhesive difficulties occurred when these women became pregnant. After ventrosuspension which gave less attachment of the uterus to the abdominal wall. As a general proposition it may be stated that those methods of anchoring the uterus which leave it with some freedom of motion independent of the bladder or abdominal wall do not interfere with pregnancy; however, since those which do either of these may not, but most likely will cause trouble sufficiently great to make their performance unwise in child-bearing women. I believe this statement now represents the general views of gynecologists.

Ventrofixation attaches the posterior fundus to the abdominal wall by union which includes the extraperitoneal tissues as well as peritoneum. Unless drawn upon with great power, as in elevation of the pregnant uterus, in which case it may give way altogether, this union tissue does not stretch.

Suspensio uteri in which the fundus is attached to the peritoneum only not infrequently results in the formation of a peritoneal band of indefinite length, independent of pregnancy. I believe there have been no especially bad results follow from this operation in pregnancy, although it is quite possible such have ensued. None of the various methods of operation which readjust the round ligaments, transplantation and doubling backing on themselves, or vaginal fixation have proved obstetrically objectionable.

In pregnant women with ventrofixation the dangers are: Premature expulsion of the ovum, excessive expansion of the posterior portion of the uterus, thinning and rupture of the uterus, mal-positions of the fœtus and the general effect of pain. Where the symptoms are indicative of these complications I favor severing the uterus from the abdomen, a very simple operation and less likely to do harm than the fixation.

Adhesions to the Broad Ligament.—Women who have had unilateral salpingectomy performed, especially for extrauterine pregnancy, are liable to sharp displacement of the uterus to that side during the first three or four months of the succeeding pregnancy. It may prove necessary in operating on the tube to shorten this base and thereby leave the uterus drawn down to the side. An interesting illustration occurred in a case of abdominal pregnancy, the fœtus dead, at full term, in which I operated. The placenta spread over all the left pelvic region and considerable shortening of the left uterine tissues was necessitated. On becoming normally pregnant later, I predicted an abortion, miscarriage taking place during the fourth month. The patient subsequently carried a child to full term. While it is the rule in performing salpingectomy to bring antero-posterior wound edges together and so preserve uterine position, yet in unilateral operation, this effort to preserve normal uterine position should be made a point of special consideration.

Displacement Due to Extrauterine Pressure.—In some of the forms of displacement under this head the latter is incidental and secondary to the cause of displacement. Such forms do not directly apply to the subject of this paper and will be only mentioned.

Pelvic Abscess.—The uterus may be sharply pressed to one side by a large accumulation of serum or pus within the broad ligament. The displacement is important only as a point in diagnosis and that leads to proper treatment of the abscess.

Appendicitis.—Appendicitis is likewise excluded from consideration here.

Ovarian Tumors and Cysts.—The frequency of ovarian tumors, and the readiness of one ovary to enlarge when the other continues ovulation, permitting impregnation and not affecting its escape during the first half of pregnancy, result in presenting complications with considerable frequency.

Heiberg gives a mortality of 23 per cent. maternal and 79 fetal in cases going to full term. The condition is, therefore, serious. The sources of evil are the increased rate of growth of the ovarian tumor from collateral blood increase, consequent decreased blood supply to the uterus and prematurity from malnutrition, torsion of the tumor pedicle, rupture of the tumor if cystic, dislocation of the uterus, subuterine dislocation of the tumor and prevention of vaginal delivery. Infection of the cyst during the puerperium has been rather frequent.

Many mistakes have been made in diagnosis. It is always best in cases of abdominal enlargement to first endeavor to determine if pregnancy exists, and if it does, to palpate from this as a base line which has a very constant set of symptoms to the abnormal features of the case. The second proposition, to determine pregnancy abnormalities, is often like catching the robin by putting salt on its tail, quite simple if only the first question could be solved. In the earlier months of possible pregnancy we practically depend upon finding the uterus enlarged and cystic and mapping its fundal boundaries. Ballottement is the one diagnostic sign. But I need not dwell on this diagnosis of pregnancy. If determined, then the most likely abnormal sign is the greater size of the enlargement, if an ovarian tumor is present, than the menstrual history would give for the uterus alone. The x-ray is helpful in showing the fœtus and giving its size. Probably the most usual cause of error in diagnosis of the combination is the failure to pursue our examination when one or the other condition has been determined.

The management of this combination requires careful discrimination. If the diagnosis is made before crowding of the uterus has begun, and the ovarian enlargement is sufficient to prevent uterine growth to full term size, it is best to remove the tumor, and the sooner the better. If the tumor is cystic, such removal is best in any case, because of the liability of the cysts to rupture during uterine contractions in labor. If no operation is done during pregnancy, the bowels should be kept carefully emptied and prompt application of an abdominal binder made after delivery, to prevent torsion of the tumor pedicle. If the size of the tumor renders its removal during pregnancy especially dangerous and full term development very difficult, we should induce labor at the latest period of fœtal viability consonant with the mother's interests. The presence of restricting adhesions, if we can discover them, should determine the induction of labor regardless of the interests of the fœtus. If the ovarian tumor is lying within the true pelvic basin, and cannot be replaced above the uterus, it should be removed through the vagina, and the sooner the better.

The mortality from ovariotomy during pregnancy is given by Dsirne (Textbook of Gynecology, Reed, p. 648), as 5.9 per cent. Pregnancy has been interrupted in 22 per cent., as given by the same writer.

The most favorable period for operating without provoking labor seems to be during the fourth month, the first months more readily permit villous apoplexy and the later months greater uterine disturbance by reason of its bulk.

Kidney Displacements and Enlargements.—I am able to report six cases of interference of pregnancy by floating kidney, given by Winckel (*Wiener* *klinische Wochenschrift* Nos. 51 and 52, 1888.) Theoretically we would expect pregnancy to act favorably, rather than otherwise, on a floating kidney by the uprising uterus pressing the kidney back into place. If the latter were both displaced and adherent the complication might prove serious.

Hydronephrosis and sarcoma of the kidney are the most prominent forms of its enlargements. Usually hydronephrosis is a result of pregnancy. It takes but slight pressure on the ureters to occlude their caliber. This is not relatively frequent in the earlier months of gestation unless uterine cancer exists.

Sarcoma is very rare. I have heretofore reported a case that was of unusual interest and complication. The diagnosis was largely determined by the presence of hematuria, in addition to the abdominal enlargement in the right side. The patient was seven and one-half months pregnant, and the kidney too large to permit full-term pregnancy. It was the size of a man's head. Labor was terminated first and the kidney removed after the puerperium. The patient, as was expected, died. It may be stated, as a general proposition, that when the removal of the complicating tumor promises to be of marked difficulty and danger, it is better to first empty the uterus and delay operation until the patient has recovered from her puerperium.

Distention of the ureter may attract attention where sudden filling of the bladder occurs in pregnancy at irregular times, preceded by a general feeling of being "ill at ease." There must be such placement of the fœtal head at the brim as to permit of pressure on the ureter to justify a diagnosis. Urine from such distended ureters shows more decomposition than normal. Charlton (*Indiana Medical Journal*, p 10, 1902) reports finding about six ounces of urine at autopsy in the right ureter. Close watch for this complication in cases of sudden reduction in the amount of urine passed in twenty-four hours, in cases connected with eclamptic questions, may give us valuable data in the near future.

Extrauterine Pregnancy.—Straus (*Zeitschrift für Geburtsch. und Gynakologie*, Bd. XLIV., H. I., 1900) reports thirty-two cases of combined extra and intrauterine pregnancies, in which thirteen continued to term. It seems extraordinary that any case ever should go to full term when we consider the usual course of ectopic gestations; but, on the other hand, no possible method of gestation ever has been conceived in imagination that has not occurred. A wandering ovum, fortified by the courage of impregnation can, like the tramp, make a bed in any spot and live on little or nothing. Of the thirteen combined pregnancies reported by Straus, there were four in which both fœtuses were living and two that were delivered alive. In three cases pregnancy went to term, with death of the "ectopers."

The proper treatment in all such combined cases would seem to be to first remove the external gestation sac by abdominal section, no matter what the period of pregnancy, leaving the intrauterine pregnancy to follow its own course.

Hernia of the Pregnant Uterus.—The varieties of hernia of the pregnant uterus are: umbilical, ventral, (between the recti abdominalis) and inguinal. Umbilical hernia is not as frequent as ventral, but may be more serious. It is possible for the uterus, which passes through a ring of tissue limited in dilatability and of considerable strength, to become constricted, swell and become gangrenous. When such condition is threatened the constriction ring must be severed and the uterus returned into the abdominal cavity if possible; otherwise, either temporary closure of the integument over the womb may be possible and support given until labor, or Cæsarian section is performed and the hernia ring closed.

Ventral hernia is usually due to excessive stretching of the abdominal wall in previous pregnancies and malnutrition, the skin and fascia relaxing, stretching and thinning until the fundus begins to enter as a wedge between the recti abdominalis. It would, on first thought, seem easy and simple to stay this form of hernia by pressure of an abdominal binder, but such is not the case. Sufficient pressure, even when applied during the middle term of pregnancy, prevents needed general expansion. Advanced cases, including the variety known as "pendulous abdomen," must frequently remain displaced until labor, as efforts to press back the uterus cause direct pressure on the heart through the intervening tissues, causing shortness of breath. We sometimes find the uterus lying in a position that is almost a complete reversal of the normal in these cases, the longitudinal axis running from the fundus below and in front of the pubes through the plane of the inlet at an angle of 45°. The fetal head may lie entirely in front of and below the pubes. In treating these cases, where replacement is impracticable, we should keep the bowels fairly empty, and have the patient wear an abdominal supporter as snugly applied as comfort will permit, the important point being to promptly attend in the beginning of labor and assist in getting the head to enter the pelvis; otherwise, a breech delivery is necessary. Nature may surprise us by bringing the head into proper position unassisted.

Inguinal hernia is very rare, but very serious. Of ten cases reported by Adams ("Hernia of the Pregnant Uterus," *American Journal of Obstetrics*, Vol. XXII., p. 25), Cæsarian section was performed in eight. Delivery was spontaneous in one.

Hernia Intestinalis.—Pregnancy and labor may be seriously affected by several displacements of the intestine, such as: Inguinal, femoral, labial and post-vaginal herniæ. The small intestine is involved, the large being seldom found.

Hernia of the intestine through a rent of the wall of the uterus into its cavity is a form that should be mentioned. I was once informed of such a case, in which the doctor exsected the loops in-utero without considering that he was removing intestine.

The best diagnostic of intestinal presence in these hernial tumors is the percussion note indicating the presence of gas. The possibility of every case of intrapelvic hernia being intestinal should always be kept in mind. Mistaking such for an ovarian cyst might easily prove disastrous. Inguinal and femoral herniæ discovered during pregnancy should be reduced, if possible, and suitable trusses applied. Posterior vaginal herniæ, anterior are very rare, found during pregnancy may make the artificial termination of pregnancy desirable, as later incarceration and rupture of the gut may occur in labor. During labor groin herniæ may be reduced between pains and then kept back by bringing the thigh close to the abdomen on the affected side and placing the patient on that side. Vaginal herniæ should be either reduced, or, if not possible, kept empty by ballooning the vagina with a colpeurynter until the advancing fœtus pushes it out. If there is much gaseous distention of the gut which cannot be reduced, Cæsarian section may be best for delivery.

Myomata Uteri.—Displacements of the pregnant uterus due to tumors in its body scarcely come within the scope of my topic.

50 West Forty-seventh Street.

A NEW SUBSTITUTE FOR SILVER NITRATE.*

BY ALBERT C. BARNES, A.M., M.D.
[illegible]

AND

HERMANN HILLE, PH.D.
[illegible]
PHILADELPHIA, PA.

For the past two years we have devoted much time to research work in the chemistry and pharmacology of the native and derived proteids and combinations [illegible] and have developed a number of interesting scientific facts which will be published in future articles. The present communication deals with a derived proteid, [illegible], and its chemical combination with silver. This new proteid is obtained in the following manner: Gliadin, one of the proteids of wheat, is extracted by means of hot diluted alcohol, evaporated to dryness, dehydrated with absolute alcohol, treated with ether and dried *in vacuo*; gliadin thus obtained is a white friable mass.

This is then heated in an autoclave under pressure for several hours with dilute hydrochloric acid whereby the new proteid arises and is obtained in white granular form by means of precipitation. This new body differs materially in elementary constitution and solubility from gliadin; the solubility of the new proteid, in both dilute and concentrated salt solutions, classifies it as a vitellin—a proteid occurring naturally in the yolk of egg and in certain plants.

This transformation of one proteid into another of a totally different character has been recorded by other investigators, *e. g.* Blenn (*Zeitschrift fur Anal. Chem.* Bd. 22, 1896), by complicated chemical treatment of egg albumen, obtained a new proteid possessing characteristics different from any known proteid. The chemical combination which our vitelline forms with silver is herewith described.

Silver Vitelline.—To a salt-solution of vitelline, obtained in the manner already mentioned, a concentrated solution of silver nitrate is gradually added until precipitation no longer occurs. The supernatant fluid is decanted, and the precipitate filtered and dried *in vacuo*. Silver vitelline is thus obtained as a dark brown powder.

The chemical and physical properties of this compound are unique. First of all, it contains 30 per cent. of silver—twice the amount of any proteid silver heretofore produced. The extreme solubility of our silver compound is remarkable. One ounce of it is freely and completely soluble in less than a dessertspoonful of water—a fact which will be wondered at by physicians who have been able, only with great difficulty, to obtain even a 5-per-cent. solution of other proteid silver compounds.

Solutions of silver vitelline, no matter how concentrated, do not precipitate albumen or sodium chloride, hence it can have no coagulating or caustic effects upon mucous membranes, nor can it be chemically changed by their secretions. The disadvantages of silver nitrate are due to its coagulating effect on mucous membranes whereby its action is limited to the surface and its penetrative power to the deeper structures prevented; it is, moreover, irritating and caustic. Briefly stated, the pharmacologic laws governing the therapeutic value of any silver compound are these: It must not coagulate albumen nor precipitate chlorides, must not be irritating, and must possess the power to penetrate into the submucous structures. It is also a pharmacologic axiom that with the above conditions fulfilled a silver salt depends for its therapeutic activity upon the amount of silver contained, i. e., the greater the amount of silver the greater its therapeutic value.

We have made a number of experiments to determine the penetrative action of silver vitelline upon the human tissues covered with mucous membrane, but the simplest one was suggested to us by Dr. Edward Martin, Professor of Clinical Surgery, University of Pennsylvania. The experiment consists in immersing a strand of ordinary catgut in a solution of our silver salt and afterwards making sections of the catgut. For this purpose the thickest piece of catgut obtainable may be immersed in a 1-per-cent. solution of silver vitelline over night; on the following morning section of the gut reveals that it is impregnated through and through with the silver. This is the severest test that can be made, and demonstrates that solutions of our silver salt have an intensely penetrating action on albuminoid structures even when they are hard, tough, and tightly compressed. The integrity or flexibility of the catgut are in no wise impaired by the immersion. The practical deduction from this experiment is that this salt will exert the antiseptic effects of silver in the deep submucous structures where, in most pathological conditions, gonococci, or other pathogenic organisms, find and maintain a lodgment in spite of energetic measures to eradicate them.

Reasoning from its chemical and pharmacological attributes, our silver compound should be valuable in the treatment of genito-urinary diseases and in the various inflammatory affections of eye and nasal passages in which silver nitrate or one of its substitutes is indicated. Through the courtesy of Dr. H. M. Christian, Surgeon-in-Chief, Genito-urinary Department of the University Hospital, an extensive trial of the compound has been made in the treatment of gonorrhœa and cystitis, both by injection and irrigation. Similar trials in the same class of cases were made by Dr. George Knowles Swinburne of New York in the Good Samaritan Dispensary and by Dr. M. Wassidlo in his clinic at Berlin.

Dr. Swinburne employed a 1 per cent. solution of the silver in sixty-six cases of acute gonorrhœa; in sixty-four of these the therapeutic effects were striking. Unpleasant symptoms were done away with entirely, the amount of discharge was markedly diminished from the start, gonococci were greatly reduced in number and the course of the disease shortened. To quote Dr. Swinburne's words, the silver solution was "not in the least degree irritating, but on the contrary, as soon as the injections were begun, the signs and symptoms of inflammation were markedly allayed." The method employed in the above cases was the injection, by Dr. Swinburne or his assistants, of a 1 per cent. solution once daily at the dispensary.

Dr. Christian employed the silver at the University Hospital by directing his patients to use the ordinary hand injection two or three times daily; he also employed it at his clinic by deep urethral injections and by irrigation. Forty cases of acute gonorrhœa were thus treated; in fifteen of these cessation of discharge occurred within ten days.

---

*Read at the third annual meeting of the American Therapeutic Society, New York, May 14, 1902.

In spite of the fact that the strength of silver solution used was as high as 5 per cent., in no instance did it produce irritation, but was of distinct value from the start in allaying inflammation, diminishing the discharge and reducing the number of gonococci. In the very acute cases a 1 or 2 per cent. solution was used; in those cases presenting themselves during the third or fourth week of the disease, the average strength of the solution was from 2 to 5 per cent. Dr. Christian states "that in a large proportion of cases the effect of the silver in checking urethral discharge was so marked that after three or four days' treatment it was difficult to secure enough discharge to stain a cover-glass for purposes of microscopic examination."

At both the University Hospital and the Good Samaritan Dispensary careful studies are being made as to the effect of the silver compound (by instillation through the catheter, and by irrigation) in cases of cystitis. In not a single case of cystitis thus far treated has a 1 to 1000 solution of the silver been productive of the least degree of irritation—a remarkable fact when one considers the extreme intolerance of an inflamed bladder to silver in any form heretofore employed, and of even half the strength above mentioned.

We have received a number of other clinical reports concerning the effect of our silver salt in the treatment of gonorrhœa and they all agree with the above in every detail. From these clinical tests it is therefore certain that silver vitelline is a valuable contribution to therapeutics, because of its penetrating bactericidal powers, absolute freedom from irritating effects and its power to allay inflammation. Its effects in gonorrhœa are uniform in checking the discharge, affording the patient freedom from *ardor urinæ* and the other symptoms of inflammation, and in shortening the duration of the disease. Dr. Swinburne and Dr. Christian express the opinion as the results of their experiences thus far with the salt that it is the best silver compound available for the treatment of gonorrhœa. Professor Martin authorizes us to quote him as follows: "I consider your silver preparation the best I have ever used; it is remarkably efficient and absolutely non-irritating."

It is safe to predict that silver vitelline will practically revolutionize the treatment of certain inflammatory diseases of eye, such as opthalmia neonatorum, purulent conjunctivitis, dacrocystitis, etc., in which silver is indicated and always employed, but in which a silver salt, which is freely soluble, penetrating to the deeper tissues, non-irritating, and at the same time contains a high proportion of silver, is regarded by oculists as a desideratum. Silver vitelline contains 30 per cent. of silver—about half the amount in silver nitrate; hence a 50 per cent. solution of silver vitelline corresponds to a 25 per cent. solution of silver nitrate with greater penetrating action, but without the caustic irritating properties of the latter. Clinical studies of our silver salt in opthalmology are now being made by Dr. A. G. Thomson of Philadelphia at the Children's and at Will's Hospital, and by Dr. Gustav Hartridge at the Royal Westminster Opthalmic Hospital, London.

In conclusion we desire to express our thanks to the clinicians who have assisted us in our investigations, and especially to Dr. H. M. Christian of Philadelphia and Dr. George Knowles Swinburne of New York for their painstaking efforts, and for the permission to quote their experiences with our silver compound.

Clinical Department.

BILIOUS REMITTENT FEVER.

By R. H. PHILLIMORE. M.D.,
COOKSHIRE, P. Q., CANADA.

It has been my misfortune to have suffered somewhat severely from bilious remittent fever, and there is nothing to my mind that so tends to stimulate a person's investigation into the etiology, diagnosis, and treatment of a disease than the fact that he himself has been its unfortunate victim. This, at least, has been my own experience. I was appointed surgeon on board a large steamship in August, 1901. We were bound for the west coast of Africa—a region which is somewhat lugubriously dubbed "The White Man's Grave." Nor is the title by any means misapplied, though this part of the coast is now not nearly so fatal to white residents as it used to be in times gone by. This is conclusively shown by comparing the statistics, published years ago by the late Sir Alexander Tulloch, with those of the present day. From his table referring to the relative mortality of remittent fever at the foreign stations of the British Army I extract the following details:

STATION.	PERIOD OF OBSERVATION.	PROPORTION OF DEATHS TO ADMISSION INTO HOSPITAL.
St. Helena,	Nine years	1 in 25
Bombay,	Five "	1 in 25
Canada,	Twenty "	1 in 16
Cape of Good Hope,	Nineteen "	1 in 15
Ionian Islands,	Twenty "	1 in 11
Jamaica,	Twenty "	1 in 8
Bermudas,	Twenty "	1 in 3
W. Coast of Africa,	Eighteen "	1 in 2

It was when we were homeward bound that an epidemic of malarial fever broke out in the ship—after our voyage up the creeks of the Niger River. So severe was the epidemic that at one time only two white sailors were in a position to attend to their work. I was the first victim, so we will charitably assume that my own inabilty to perform, for a number of days, my official duties was responsible, to some extent, for the rapid spread of the disease.

Before, however, relating my personal experiences on this voyage, permit me to briefly refer to the nomenclature and history of this form of paludal fever. There is, I suppose, no disease which passes under so many aliases as bilious remittent fever. Wherever it prevails it seemingly acquires the name of the district or locality. Thus in Africa it is termed the African fever; in the Netherlands we find it described as gall-fever—a by no means inappropriate appellation. In the Mediterranean it is called the Mediterranean fever. Other synonyms are the Walcheren fever, Hungarian fever, jungle fever, Bulam fever, Bengal fever, Puka fever of the East Indies; while in America it is not infrequently described as lake fever. It is also sometimes designated as country fever, river fever and marsh fever.

This remittent form of malaria dates back to very ancient times. Among the Greeks its ravages in that part of the plain of Argolis, which is known as the marshes of Lernœa, were so great that the disease was personified as a many-headed hydra—to-day we might more appropriately represent it as a magnified mosquito; and my classical readers will doubtless remember that it became one of the labors of Hercules to overcome this terrible and death-dealing monster. Hippocrates, the illustrious descendant of Æsculapius, also observed that an enlarged spleen was due to drinking marsh water.

In regard to the mode of introduction of the malatal passing into the human system. But of course, this [illegible] is a fertile source of [illegible]. For my own part I believe that drinking polluted water is the principal origin of the malady. And here I cannot help quoting one important instance: "In 1894 certain [illegible] soldiers all in good health, embarked in three vessels to sail from [illegible] to Majunga. They all arrived at Majunga the same day. In two vessels there were [illegible] men without a single sick person; in the third vessel the Argo, there had been [illegible] during the passage, and of the 119 survivors no less than ninety-eight were [illegible] with all forms of paludal fevers. This was due to the water supply. In the two healthy ships the water was good, but the soldiers in the Argo had been supplied with water from a marsh which had a disagreeable taste and odor." Now, the experience which I had on my voyage demonstrated very clearly that the origin of the trouble could be traced to the water supply. At any rate we may exonerate the mosquito. On the 9th of November the health of the ship was excellent. From that date till the 24th every officer and sailor on board the vessel, with the exception of two men, was incapacitated more or less from duty. In addition to this, I may mention that upon making inquiries of the surgeons on other ships, I was informed that no outbreaks had occurred, and yet we were all in the same locality, subject to the same meteorological conditions, and all equally exposed to attack. I understand that we had taken in a fresh supply of water at one of the ports—a circumstance which would absolutely confirm my suspicions.

The following account of my own case may prove of interest to your readers.

My attacks were as follows:

	DATE	DURATION
1st attack of bilious remittent	Nov. [illegible], 1901	Six days.
2d " " "	" 2[illegible], "	Six days.
3d " " "	Dec. [illegible], "	Four days.
4th " " "	" 15, "	Four days.
5th " " "	" 26, "	Three days.
6th " " "	Jan. 6, 1902	Three days.
7th " " "	" 15, "	Twelve days.

About twenty-four hours prior to the actual manifestation of the disease I suffered from a sense of malaise. I was "off chop," as they say on the coast. This was followed by extreme nausea, and on the 9th of November I vomited large quantities of bile. This vomiting was most persistent and distressing. My temperature in the morning was 104°, pulse 120 and bounding. I was restless and sleepless, but I experienced no perceptible chills, neither did I suffer from headache. Thirst was intense. In the evening my temperature was 104.2°, and for the next three days it fluctuated between 101° and 104°. On the 10th and 11th vomiting was still uncontrollable, and I felt weak and depressed. I was, during all this time, treated by an old coaster. "Pile on the blankets," he would say; "there now, as long as you are sweating and that prickly heat shows well, you are all right." Then he would add the comforting remark: "If you don't sweat, and you show no prickly heat, you are a dead dog! And, whatever you do, keep your belly warm." All old coasters, I may mention, wear a bandage around the abdomen; they think far more of this than they do of their prayers. When I recovered from my first attack I found several of the crew worse off than myself. Two of my patients presented well-marked typhoid symptoms—tongue brown, parched and cracked, tenderness of abdomen, with uncontrollable vomiting, and an anxious expression of countenance. These paludal-enteric types gave me much anxiety, and were practically indistinguishable from typhoid fever, except that the temperature chart was not [illegible] with the [illegible]. In some cases the temperature rose [illegible] 106.8°, but, strange to say, a high temperature did not always appear to indicate the severity of the disease. During my second attack, for example, when the thermometer registered [illegible], I felt [illegible] more comfortable than when it registered 103° the previous day.

That bilious remittent fever is infinitely more to be dreaded than the intermittent form is, I believe, generally recognized. During the outbreak of which I speak one sailor died, a man over sixty years of age. This patient suffered from intense jaundice, extreme depression and a feeble pulse. His temperature never rose above 101°. He became delirious at night, and the administration of quinine entirely failed to relieve his condition. In every case the nervous symptoms were very pronounced, while total abstainers apparently suffered more severely than those accustomed to the use of alcohol. This, of course, may have been a mere coincidence, though I was informed by a number of old coasters that total abstainers did not appear so well able to resist the attacks of malaria as other persons who habitually indulged in alcoholic stimulants. It must be clearly understood, however, that I am not making any authoritative assertion. I am simply repeating what I was told upon several occasions.

In conclusion, I am in hopes that the foregoing remarks on bilious remittent fever may call forth the experiences of other readers of the MEDICAL RECORD who have visited the west coast of Africa.

The Anatomical Factor in the Production of Baldness.—George Elliott says that the skin of the scalp overlying the epicranial aponeurosis has no underlying muscles to exercise it, and has only the action of the occipito-frontalis to depend on, and moves only when that muscle is put into action. That is not often. The scalp is very vascular, there is nothing to interfere with or retard the arterial supply, but there is also nothing to accelerate the return flow—no active muscular exercise in the part whatever, to hurry along the waste products and the deoxygenized blood in the vessels. These structures being superficial, and easily compressible, their compression by the rim of the hat will further retard the flow. In women the scalp is well exercised by the combing, plaiting and throwing from side to side of the hair—men scarcely give more than a moment to the brushing and combing of their hair. Massage is the treatment to be applied, especially as a preventive.—*Dominion Medical Monthly*, March, 1902.

Treatment of Tuberculosis by Spectral Analytical Blue Light.—Sterkel and Gustav Kaiser have conducted numerous experiments with blue light on bacilli, with the result that the bacilli were killed or else much enfeebled. Operations were then begun on tuberculous patients. After six weeks treatment, with six sittings daily, the night-sweats and bacilli in the sputum disappeared, notwithstanding bad weather and indifferent circumstances. In a second patient, who had a tuberculous ulcer on the leg, this healed within four weeks. An eczema of six months' standing was healed within five weeks. These results confirm the theoretical assumption that the blue or the ultra-violet rays are bactericidal; that the heat of the rays can be abrogated, that the intensity of the light is in proportion to the distance; that the blue rays are a powerful absorbent; and that they are also anæsthetic.—*Medical Press and Circular*, March 26, 1902.

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

PUBLISHERS

WM. WOOD & CO., 51 Fifth Avenue.

New York, May 24, 1902.

SURGERY AND MITRAL STENOSIS.

It has long been recognized that the medical means at our command for combating the effects of mitral stenosis are tentative and unsatisfactory, and the possibility of mechanical relief for the overloaded ventricle has frequently been discussed. In the *Lancet* of February 8 of this year Lander Brunton gives the results and the conclusions drawn therefrom of a number of experiments upon animals, and he suggests the possibility of relieving the circulation in the human being by incision of the stenotic mitral ring with a narrow-bladed tenotome, passed through the ventricular wall and operated largely by the sense of touch.

Brunton's experiments and a few reported experiences in cardiac surgery in man have proved that the heart is much more tolerant of handling and manipulation than was supposed to be the case a few years ago, and it has more than once been suggested that an aspirating needle be plunged through the chest wall into the distended ventricle in cases of stenosis of the auriculoventricular openings, so that, by the withdrawal of a certain amount of blood, the laboring heart might be relieved. This suggestion was never favorably received, and has rarely been acted upon for obvious reasons. No such uncertain and unsurgical procedure would be thought of at the present day, since the surgical *sine qua non* of an operation of such boldness and danger would be a proper exposure of the part operated upon, which in this instance would necessitate an osteoplastic resection of the thoracic wall. This is, of course, in itself a formidable procedure, especially in a patient with a disordered circulation to begin with, and it is hardly necessary to say that patients with cardiac disease are not good subjects for anæsthesia. However, we have no doubt that in some carefully selected cases of mitral stenosis the mere exposure of the heart could be accomplished without any prohibitory mortality, though carrying the operation further would probably make a very great difference in the percentage of recoveries. It is not at all certain that, even if the heart were successfully exposed, any reasonably accurate work could be done toward dividing the stenotic ring. The technical and physiological difficulties would necessarily be enormous, and working with a tenotome in the interior of a pulsating heart does not present any great attraction to the surgeon. Experiments upon animals and in the dissecting room would undoubtedly greatly increase the deftness of the operator and increase his chances of success.

It would probably be difficult to get the consent of the average patient for such an operation, and it is a question whether the surgeon would be justified in recommending it, since the chances of immediate and remote success would be very difficult to estimate. A further consideration depends upon the nature and extent of the changes, which may have already occurred in the heart, lungs, liver, and kidneys, the bearing of which upon expectation of life are not always clearly marked until some unusual physical or physiological strain accentuates them, and, as we know, a surgical operation often supplies such a strain.

The selection of cases would involve almost as much difficulty and responsibility as the performance of the operation, but we may be sure that we should only occasionally meet a case in which all conditions were such that we should recommend any treatment which would mean serious surgical work, apart from the intrinsic dangers of the procedure in question. Anatomically speaking, exposure of the heart is an operation which requires great care, but which, in itself, is not specially dangerous. It must be remembered that operators who have found it necessary to expose the heart in attempting to close wounds in its wall have found that its action always becomes tumultuous and irregular when it is handled or when its walls are pricked with the needle. This fact increases the difficulty of accurate manipulation very seriously. It is still too early to draw any positive conclusions in regard to this bold form of surgical intervention, but there is some reason to believe that the future will establish its limitations more definitely, and assign to it a measure of usefulness.

MEDICAL LITERATURE.

A CRITIC once ventured the opinion that the readers of most literary productions drew the line, variously placed, between being properly edified on the one hand and being becomingly bored on the other. Further than this he was free to say that very many of the books and articles were scarcely read at all save by those whose duty it was to tell how worthless they were. The main ends of the hopeful authors were thus rendered entirely purposeless. This outcome of laudable effort was not due so much to lack of knowledge of the subject as to the style and method of its preparation.

All this applies so directly to the medical literature of to-day that it can serve as the excuse for some general considerations bearing upon the proper means to a given end. The medical man, as a rule, should, by virtue of his cultivated powers of observation, be a good writer. He is trained to observe and interpret facts, and he should have an equal power in expressing them. That this is the exception in a very general sense rather than the rule, is painfully evident in the dull and wordy pages of our many medical treatises and in the long, stupid, and tiresome articles that so often fill the columns of our medical periodicals.

When a great painter was asked by a pupil how he mixed his colors, the significant reply was, "With brains, sir." Another artist solicited to criticise a picture, after commenting on the conception, the coloring, and perspective, offset all his praise for the work in general by emphatically [illegible] with an appropriate picture, that pleased [illegible].

Both judges had the proper appreciation of the real art of putting things—the proper composition of picture and setting. It was not the mere [illegible] of an idea but its practical application to the mental receptivity of the one for whom it was intended. No one needs be told that the bold or the [illegible] has any other reason for its existence than the necessity of sale. The question of art of what should concern every writer who wishes to make the proper touch with his readers. It is the instinct of precision and directness at the start and its proper continuation afterward. It is the saying of the thing to be said and knowing when to stop.

Tedious writers rarely, if ever, escape being tedious and their number is legion. They inflict themselves upon us at every opportunity, and write against time and space, so that the mere title of the article is of itself enough to forbid further reading. What should be in one volume is amplified into a series, and one page of facts is diluted into ten of sentences and inapplicable theories. The difference in interest of many medical articles is strikingly manifest from this point of view. A practised writer handles his pen as an artist does his brush. The subject is balanced properly from all sides and the fine touches bring in the high lights with their proper telling effects. It is the presentation of the salient facts as they appear to the practised observer—what interests him interests his reader.

Scientific writing, dealing, as it does, with facts should be necessarily terse in style, but this is no argument against decent literary finish making easy and interesting reading. The medical man who is skilled in descriptive writing has a better opportunity for exercising his talent than most authors in any other line of work. In fact, his field has been so constantly trenched upon by makers of fiction that there is no excuse on the score of lack of material for most finished literary efforts. What may be imagined by the novelist is real with him. He has simply to describe what he sees day after day in hovel or palace, and the actual drama of human suffering shows itself in all its terrible and realistic outline. The more accurately the clinical phenomena are presented, the more useful and interesting they become. What finer medical classic, with its easy narrative style, its accurate pictures of diseased conditions, its charming rhetorical allusions, and its graceful rendering of classic English, can be found than "Watson's Practice of Medicine," which was to medicine what Blackstone was to law, but where are their equals to-day? The ancient writers were models of their kind in accurate delineation of clinical phenomena, and their facts stand for all time. We know their statements were truthful because we verify them every day centuries after they were written. Theories have come and gone, but with ever-changing views as to the reasons for this or that symptom, we rehearse the incontrovertible fact every time we feel a throbbing pulse, listen to hurried pant, note a sluggish pupil, or watch for the face of death. The picture is always before us, but the hand of the present-day delineator is fast losing its cunning. We are drifting into mechanical methods and working in ruts. Our books are arranged on stereotyped plans, and individuality is lost in efforts to cast our figures in conventional moulds. It is [illegible] against [illegible]. Aspiring medical journals pride themselves on the amount of paper they can print and the quantity of paper that can be wasted. The [illegible] given [illegible] for the what—the form for the substance. Those who are accustomed to read manuscripts for publication and to wade through books for review know how few good writers there are. But the touch of the master hand is seen as readily in the first paragraph as in the last sentence. When the latter is [illegible] the reader takes a second look and [illegible] and probably goes on to the end. If the writer is seeking a large and appreciative audience his first thoughts should be brevity, terseness, and point, centralizing his best efforts in the direction of the parallel cardinal virtues—faith, hope, and charity—the last the greatest for the expectant reader.

THE FAILURES OF STERILIZATION

It has become almost an article of faith with the general public and some medical men that sterilizing is necessary to render milk a suitable food for young children, so that the doubt cast upon the method by certain prominent physicians, and especially by Dr. Victor Vaughan of Ann Arbor, Mich., comes in the nature of a surprise.

Dr. Vaughan read a paper before the Section on Diseases of Children at the fifty-first annual meeting of the American Medical Association, in which he set forth his views on the subject.

He said that he was sure that the sterilization of milk, as ordinarily carried out, and even the pasteurization is not desirable, but that perfectly fresh milk from the cow, with certain common-sense modifications, is the best food for the baby. The chief proteid in milk is a nucleoalbumin, and there is no question that it is changed by high temperature.

As to the temperature at which this change takes place Dr. Vaughan states that the result of numerous experiments has convinced him that it is fairly high. A milk heated to 158° F. shows but little change, a milk heated to 160 F° shows quite a marked change. If the milk be heated long enough and two or three times, it can be fairly well sterilized by heating not higher than 158° F.

In his opinion the high death rate from the summer diarrhœas, which continues, notwithstanding the sterilization of milk, is due to failures in sterilization. The colon germ is the most frequent bad germ in milk, being almost universally present in market milk. This germ varies exceedingly in virulence. If a colon germ of moderate virulence be taken, its virulence can be so increased that .05 c.c. will kill a guinea-pig of a given weight in two or three hours.

The colon bacilli, and probably other bacilli, grow rapidly in milk under certain conditions, and there is no amount of sterilization known that will destroy the toxin of the colon bacillus. If some of these bacilli are grown on an agar culture for two or three weeks and then scraped off the surface growth, the germ can be heated to 160° C. or 356° F. in a sealed tube with water, and there will not be the slightest effect produced upon the toxicity of the poison. When, according to Dr. Vaughan, you can get a colon bacillus that furnishes a poison one-fourth of a milligram of which—1-270 of a grain—will kill a guinea-pig, some idea can be formed of the powerful toxin that this germ produces, and impossibility of destruction by any method of milk sterilization that can at present be practised.

Our aim must therefore be to take care of the milk and to prevent its contamination.

No amount of sterilization, Dr. Vaughan asserts, can make milk containing this germ sterile. The colon germ has an envelope varying greatly in its resisting power, according to the virulence of the germ. The toxin is contained within this envelope. If you will take some of the colon germs, grow them, scratch off the germ cells and put them in artificial gastric juice and leave them there, it will completely dissolve the cell wall and leave undigested the substance which will kill guinea-pigs in a dose of 1-270 of a grain. No amount of heat up to 160° C or 356° F has been found to have the slightest effect on the toxicity of this poison, and a milk which is already a good culture of colon bacillus cannot be made safe for a child by any known method. We can kill the germ, but we cannot get rid of the poison.

These conclusions, reached by the painstaking investigations of so well-known an authority as Dr. Vaughan, would seem to clearly demonstrate the fact that sterilizing milk has its limitations, and, indeed, is a more or less ineffective process of producing a nourishing and healthful infant food. The theory that the act of boiling milk at a high temperature destroys all its properties hurtful to a child of tender years and renders it an ideal food has been over-ridden.

The procedure most worthy of adoption to attain this object is a careful and rigid supervision of the cows and the dairies, in order to ensure the delivery of milk as free from contamination as possible.

The present-day knowledge of germs is not nearly so full and exact as believed by many, and the bactericidal action of the typhoid bacillus is still a stumbling block to investigators.

Foundlings of a Great City.

A writer in *Ainslie's Magazine* for May gives a very excellent description of the manner in which the foundlings of New York are cared for, and how immensely improved is the system of rearing destitute children to that in force but a very short time ago.

The abandoned young ones only four years ago were first taken to Bellevue Hospital and then to the Infant Asylum on Randall's Island, where the little waifs, despite the best of care and nursing, literally, died like flies. The mortality at that institution during a certain period reached almost 100 per cent.

This appalling death rate at length became so great a scandal that two large charitable associations caused an investigation to be undertaken, and it was resolved to alter the system of caring for these infants. It was decided that thereafter the babies should be taken to Bellevue and, to some extent, be built up, but that from Bellevue they should be nursed out in individual homes, the homes to be supervised and selected by special agents employed for that purpose alone. The plan had been adopted elsewhere in America, as well as on the European, continent with surprisingly good results.

The first report under the change was made in 1899. It showed that the death rate had fallen from 98 per cent. at Randall's Island in 1895, 99 in 1896, and 100 per cent. in 1897 to $55\frac{9}{10}$ per cent.

The second report showed a still further decrease to $31\frac{1}{10}$ per cent., and at the present time the percentage of foundling deaths is below 15 per cent.

Mr. Robert E. Macalarney, the writer of the article in *Ainslee's*, gives a pleasing description of the manner of life and training of these deserted children.

The Effect of Inoculation against Typhoid Fever.

A vivid interest is being shown everywhere at the present time, with regard to the etiology and means of prevention of disease, and of none can this fact be more truly stated than of typhoid fever.

The opportunities for studying this affection have been exceptionally favorable during the long protracted campaign in South Africa, and it may be said that our knowledge of the disease has been proportionately increased.

The theory advanced by Dr. Victor Vaughan and others, while the Spanish-American campaign was in progress, that probably flies played a somewhat important part in spreading the infection of enteric fever, would seem to have received a certain amount of confirmation from the recorded observations of British surgeons in South Africa within the past few years.

With respect to inoculation against typhoid fever, although some undoubtedly valuable information has been gained, no convincing proofs that the method is of any striking and definite value as a means of prevention have been forthcoming.

Brigade-Surgeon Lieutenant Colonel Crombie, late of the Bengal Department of the British Indian Army, gives in the *Lancet* of May 3 some statistics on the subject. from evidence afforded by the war in South Africa.

Of 250 officers who recently came before the Medical Board, London, invalided from South Africa on account of wounds and disease, it was found that 112, or 44.8 per cent., had been inoculated against enteric fever; that 29, or 11.6 per cent., had had previous attacks of typhoid, and that 109, or 43.6 per cent., had not been inoculated or had a previous attack. Of the total number (250) 59, or 23.6 per cent., suffered from enteric fever in South Africa, but of these a considerable number were actually invalided on account of debility following enteric fever, so that this latter percentage cannot be put forward as representing the real proportion of officers so infected. It is, of course, considerably higher than the actual ratio. Of the 112 who were inoculated, 32, or 28.5 per cent., suffered from typhoid. Of the 29 who had had a previous attack only 3, or 10.3 per cent., had a second attack in South Africa, and of the 109 not inoculated, 24, or 22 per cent., had attacks in South Africa. Of the 112 who were inoculated, 102 had been inoculated once, with thirty cases, or 29.4 per cent., and 10 with two cases, or 20.0 per cent., had been inoculated twice.

It is stated that there would seem to be a very general consensus of opinion among medical officers in South Africa that inoculated cases run a milder and more favorable course than those not inoculated. According to the statistics of Dr. H. H. Tooth this leads to a higher percentage—2.5 per cent.—of re-common among men and, for obvious reasons, it would probably be higher among officers.

These inoculations would seem to afford a certain amount of protection against typhoid fever.

WAR OFFICE "SWEATING" OF CIVILIAN SURGEONS.

The policy of the government of the United States with regard to its treatment of contract army surgeons has not been characterized by any marked degree of liberality, and has in many instances given rise to much dissatisfaction.

The British War Office, however, according to medical journals, has acted in a particularly mean spirit towards the civil surgeons engaged for the South African war. General parsimony has not been a distinguishing feature in the history of the South African campaign; money has been poured out like water, and the Boer war will undoubtedly rank as one of the costliest ever undertaken. With respect to the medical branch of the British service, an altogether different tale has to be told, and no economy has been too small and petty for the authorities to practise.

The unfortunate scandals connected with the hospitals and the refugee camps in the South-African war have been largely owing to the undermanning and defective organization of the army medical service.

The *Medical Press* says that at home the military hospitals, by the withdrawal of every available army surgeon to the seat of war, left gaps which have been filled by civil surgeons. The latter have been paid at the miserable rate of $1,350 per annum, less than $500 of gratuity given to all other branches of the service. They have been also hopelessly overworked, as there are not enough of them to discharge adequately the duties required of them. At Aldershot the civil surgeons in the military hospitals are being "sweated" with little pay and excessive work in a manner that is discreditable to the nation and likely to be harmful to the patients. A more liberal scale of pay, say $1,825 a year, would quickly draw enough competent medical men for temporary service.

The miserable rate of pay and the excessive amount of dirty work demanded in return are not likely to secure the best men available. A few of the many millions that the war office has handed over to swindling contractors for the purchase of horses and preserved meat would have put the army medical service on a sound footing, both at home and at the seat of war.

It appears that the United States government does not possess the monopoly of evil fame either for providing its soldiers with preserved meat of questionable quality or for niggardly treatment of its contract army surgeons. There can be no doubt that such a policy is a penny wise and pound foolish one, for an able army medical service is essential to the well-being of the troops.

It is well that the faults in the army medical service should be thoroughly ventilated in the medical press, for by these means will reform come.

THE HEALTH OF HAVANA.

The health report of Havana for the month of March, just received, gives a death rate of 20.85, which is less than that of Baltimore, New Orleans, New York, San Francisco, Liverpool, Manchester, Edinburgh, Barcelona, Madrid, and many other cities of the United States and Europe.

Six consecutive months have now passed without the occurrence of a case of yellow fever in Havana, which seems abundant evidence that the disease has been eradicated from that city. In bringing about this result the sole effort on the part of the health authorities has been bent toward the destruction of the mosquito. This general work against mosquitoes has naturally worked for the reduction also in the number of cases of malarial fevers, and the health officer, Major Gorgas, is confident that malarial disease would be eradicated from Havana as yellow fever has been, if it were not constantly being introduced from the surrounding country. The sanitary statistics of Havana show that there were nearly 350 deaths from malarial fever in that city in 1900. In 1901, the first year of work against the mosquito, the deaths fell to 151, while during the month of March of this year there were only 4 deaths from this cause. Economically considered, Major Gorgas says that the work of mosquito destruction during the past year has cost about $50 000, has given work to an average of about 100 men, the return for this expenditure is represented by the extermination of yellow fever, which formerly cost 400 lives annually, and a saving of about 250 lives annually from malarial fevers. This does not take into account the number of sick who recovered, and who do not figure in the mortality statistics.

The energies and attention of the health authorities of Havana are now directed principally against tuberculosis, which has always been the cause of the greatest mortality in that city, as it is everywhere else. So far the death rate from this disease has been reduced to about three-fifths of what it was during Spanish domination. During the month eighty houses, which had been occupied by consumptives, were disinfected. A dispensary for the tuberculous has been established, and medical inspectors, who dwell very extensively upon the subject of tuberculosis, are systematically sent to tenement-houses and tobacco manufactories. A total of 138 public lectures on hygiene was delivered during the month. It is believed that there are about 2,700 cases of tuberculosis in Havana, of which 2,500 have been recorded and classified for reference. Popular literature has been sent to those affected, explaining the character of the disease, its communicability, and the best method of care in its prevention and treatment. Major Gorgas believes that if this system can be continued for four or five years tuberculosis can be eliminated from Havana as yellow fever has been.

The Value of an Occasional Convulsion in Certain Cases.—William P. Spratling states that two classes of individuals have come under his observation in which occasional convulsions were productive of good. The first includes epileptics in which prolonged periods of mental disturbance or insanity are prevented through the occurrence of a fit; the second, selected cases of incipient alcoholism, in which a persistence in the drinking habit would probably lead to confirmed epilepsy were it not for the emphatic warning given by the convulsion. Epileptics of a certain type make up the first class, which includes those in whom the disease seems dependent on fluctuating internal causes, on the action of certain toxins as yet unisolated which grow in intensity until a limit is reached, when their toxicity is, in some manner neutralized or destroyed by a convulsion, only to repeat again and again the same process of development, growth, and decadence, the latter occurring each time as the result of one or more epileptic convulsions. In some, perhaps in all alcoholic cases, a convulsion may, perhaps, be regarded as only a protest on the part of the nature against the presence of an irritant of some kind in a part of the body where it ought not to be, and it only remains for science to locate and determine the nature of the irritant.—*Albany Medical Annals.*

News of the Week.

American Medical Editors' Association.—The annual meeting of this association will be held at Saratoga Springs, N. Y., June 9 and 10. The annual dinner of the association will be given at the Hotel Kensington on the evening of June 9. The officers of this association are Dr. Alexander J. Stone of St. Paul, *President*, and Dr. O. F. Ball of St. Louis, *Secretary*, to whom all correspondence should be directed.

Segregation of Lepers in Guam.—A number of cases of leprosy have been found among the natives of the island of Guam, and steps have been taken by the medical authorities of the Navy for their collection and segregation. The establishment of a permanent colony on thirty acres of ground on Tumon Bay Beach, within practicable reach of Agana, the chief town of Guam, by a fairly good road, is intended. Steps have already been taken to acquire this ground and plans are being prepared for the necessary buildings. It is understood that the nursing of the unfortunates will be undertaken by a Catholic religious organization. The report says: "It appears that during the interregnum immediately following the withdrawal of the Spanish government from this island, the lepers gradually slipped out of the Asan hospital, being received and cared for by the kind-hearted people of the villages, who are loath to betray them. When the last inmate died it was generally asserted that the disease was practically extinct; several reported cases proved, upon examination, not to be leprosy, and such search as was feasible failed to discover any until now. It is believed that no material harm in the way of dissemination has resulted from this recent lack of segregation."

A Martinique Relief Expedition has been sent by the Army Medical Department in aid of the sufferers of the Martinique disaster. The personnel of the expedition consists of Lieuts. J. B. Clayton, J. R. Church, and J. H. Reilly, assistant surgeons, and six enlisted men of the Army Hospital Corps. The complete equipment for two regimental field hospitals of twenty-four beds capacity was taken along, together with about $5,000 worth of medical supplies for issue to the sick. It was expected that the services of the relief expedition would not be required in Martinique more than about three weeks.

Emergency Hospital for the Grand Army of the Republic.—During the coming encampment of the G. A. R. in Washington, D. C., a large building will be secured and fitted up as a temporary hospital, in addition to the hospital accommodations which could be afforded by the local hospitals during the period of the encampment. The age and feebleness of many of the veterans make it certain that a very large number of cases will require medical treatment. Dr. Percy Hickling is chairman of the medical committee.

The Summer School in Philanthropic Work, conducted by the Charity Organization Society in New York, opens its fifth annual session June 16, continuing six weeks. It consists of a series of discussions and visits each morning, combined with practical work in the afternoon, intended to introduce the students to life among the poor in New-York, and the best means toward improving their condition. The Director of the School is Mr. P. W. Ayres, 105 East Twenty-second street, New York City.

Medical Deputies in France.—The recent elections in France have resulted in the return of forty-three physicians to the Chamber of Deputies. Of this number twenty-eight have been re-elected, and fifteen will undertake legislative duties for the first time.

Fire at the Naval Hospital.—Fire in a store-room of the U. S. Naval Hospital in Brooklyn, one day last week, destroyed about $25,000 worth of drugs, chemicals, and other articles belonging to the medical department. The building in which the fire occurred was formerly used as a laboratory, and stands in the rear of the hospital building. Lately the main floor has been used for offices and by the United States Naval Examining Board. The hundred patients in the hospital were not alarmed, as the fire was some distance from them. Improperly insulated electric light wires probably caused it.

The Spitting Nuisance.—According to an amended ordinance, which was adopted by the Health Board of this city a few days ago, spitting upon the sidewalks or upon the floors of public halls, of tenement houses, theatres, hotels or other public buildings is to be a misdemeanor, and the offender will be liable also to pay a penalty of $50 recoverable in a civil action by the city. Other provisions of the new law provide that all tenement owners, hotel men or theatrical managers shall have printed notices stating the law posted in prominent places and that they shall supply sufficient cuspidors.

The Yale Medical School.—At the May meeting of the Yale University Corporation, two new clinical professors were elected in the medical school: Arthur N. Alling, M.D., Columbia, '91, to be clinical professor of ophthalmology, and Ralph A. McDonald, M.D., Yale, '92, to be clinical professor of dermatology.

An Emergency Medical Service in Congress.—The House of Representatives in Washington is to have a medicine chest in the office of the sergeant-at-arms. The resolution introduced last December by Dr. Wilson of Brooklyn, directing the sergeant-at-arms to purchase an emergency case of medicine, and suitable instruments for minor operations for use in case of illness or accident to persons in attendance at the House, was favorably reported recently by the Committee on Accounts, with an amendment providing that the contents of the case be selected by Representatives Wilson of New York, Ball of Delaware, and Showalter of Pennsylvania, all members of the medical profession. A medicine chest may do for the House, but in order to meet emergencies in the Senate a well-stocked case of surgical instruments would be imperatively necessary.

American Laryngological Association. — The twenty-fourth annual meeting of this association will take place in Boston on May 26, 27, and 28. The session will be held in the Boston Medical Library Building and the Harvard Medical School. Dr. John W. Farlow of Boston will preside. The secretary is Dr. James E. Newcomb, 118 West Sixty-ninth street, New York City. The program contains the titles of a number of papers which promise to be most interesting.

Association of Military Surgeons of the United States.—The eleventh annual meeting of this very active association will be held in Washington on June 5, 6, and 7, under the presidency of Lieut.-Col. John Van R. Hoff, Deputy Surgeon-General, U. S. A. The Secretary is Major James E. Pilcher, Brigade Surgeon, U. S. V., Carlisle, Pa. Invitations have been sent out through the State Department to the various governments to send delegates, and the responses have been such as to lead the officers of the association to expect a large representation from the medical departments of the European armies and navies. Many plans are being made for the entertainment of the members and their guests, the following being the program so far as determined upon: June 4, from 8 to 11 P.M., an informal reception at the New Willard; June 5, exhibition drill of hospital corps at the Washington Barracks from 3 to 5 P.M.; excursion down the river from 5 to 11 P.M.; June 6, reception at Soldiers' Home from 4 to 7 P.M.; June 7, banquet at New Willard Hotel, 8 to 12 P.M. The Chairman of the Committee of Arrangements is Major George Henderson, D. C. N. G., Washington. The convention will be opened by President Roosevelt. The Secretaries of War, Navy and the Treasury will also be present at the opening meeting, and the attendance of General Miles and Admiral Dewey is also expected. It is desired that all ex-surgeons of the Spanish-American War, whether members of the association or not, will attend. The papers to be discussed will be on the following subjects: (1) The National and State Services; (2) Hygiene and Sanitation; (3) Tropical Service and Tropical Diseases; (4) Military Surgery and First Aid; (5) Military Hospitals and Nursing; (6) Miscellaneous.

The Retirement of Surgeon-General Sternberg.—The bill providing for the retirement of Surgeon-General Sternberg with the rank and pay of major-general has been favorably reported to the Senate by the Committee on Military Affairs. Dr. Sternberg's many friends and admirers purpose giving expression to their appreciation of his long and faithful services to the country and the medical profession by a dinner, to be held in this city on June 13. Those wishing to join in this recognition of Dr. Sternberg's scientific labors, of his professional standing, and of his high personal character are invited to be present at this dinner. The subscription is $10, which shall be sent to Dr. Hermann M. Biggs, 5 West Fifty-eighth street, New York City.

Society of the Alumni of St. Luke's Hospital.—At the annual meeting of this society, held last month, the following officers were elected: *President*, Dr. J. Arthur Booth; *Vice-President*, Dr. William H. Sherman; *Secretary*, Dr. W. Scott Schley; *Treasurer*, Dr. J. Bentley Squier.

The Late Professor Paul F. Munde.—*Whereas*, In the death of Dr. Paul F. Mundé, the Woman's Hospital Society has lost one of its most earnest and active members, who had won, through his ability and energy, a most eminent and honorable position.

Be it Resolved, that this society express its deep regret at a loss which will be felt, not by it alone, but by the entire medical profession as well, and that we extend to his family our sympathy.

Be it further resolved, that a copy of these resolutions be forwarded to his family, and also that they be placed on the minutes of the society.

LeRoy Broun, M.D.
James N. West, M.D.
Committee.

Philadelphia County Medical Society.—At a stated meeting held May 14, Dr. Chas. W. Leaver exhibited "A New Inhaler Especially Intended for Use in Operations on the Eye and Face." It consists of metal and comprises a mask for the nose and mouth connected at an oblique angle with a hollow cylinder expanding into a cup-shaped receptacle covered by a cap in which a bit of gauze can be placed for the reception of the anesthetic. It is provided with two valves, one opening outward and the other inward, permitting the escape of exhaled air and the entrance of air for the admission of the anesthetic vapor. Drs. Jas. Thorington and Geo. C. Harlan testified to the successful use of the apparatus in a number of operations. Dr. Thos. C. Ely read a paper entitled "Cyclic Vomiting in Children, with a Report of Cases." He designated the condition a toxic neurosis of metabolic origin, the gouty diathesis being an etiologic factor in some of the instances reported. Eliminants and sedatives proved to be the best remedies, the most serviceable of the latter being morphine hypodermically. Dr. J. P. Crozer Griffith suggested the designation recurrent vomiting. Dr. John B. Shober read a paper entitled "Infection of the Female Bladder, Diagnosis and Treatment," and reported a case attended with ulceration of the vesical mucous membrane. Gonorrhea and parturition appear to be the most common causes. Cystoscopic examination is necessary for diagnosis, and an instrument was shown with the aid of which the bladder could be readily illuminated and inspected and catheterization of the ureters practised. Topical treatment also can be most conveniently applied by means of the cystoscope. For this purpose salts of silver are useful, as is also powdered adrenal gland for the control of hematuria. Dr. Alfred Gordon read a paper entitled "Saline Infusions and Their Administration for Meningeal Symptoms in an Infant." He related the case of a child some seven weeks old, in which symptoms of cerebral irritation developed in connection with gastro-intestinal derangement. A fatal issue seemed imminent, but relief was afforded by injecting slowly beneath the skin about ten ounces of normal salt solution in conjunction with the administration of solution of nitrous ether, with ultimate recovery.

Philadelphia Pediatric Society.—At a stated meeting held May 13, Dr. A. H. Davisson made an "Exhibition of a Cretin Shown a Year Ago." The child had intermittently been kept on thyroid extract, and notwithstanding the development of an acute intercurrent disease followed by prolapse of the bowel, it had improved. Dr. Davisson exhibited also "A Case of Paraplegia in a New-born Infant." The child was now seven weeks old. There had been much difficulty at birth, the feet presenting and being delivered first, the head last. The paralysis was flaccid in type and involved, in addition to the lower extremities, the muscles of the trunk and the chest, with the exception of the diaphragm, and with it was associated apparently anesthesia of the same parts almost to the level of the nipples. Hemorrhage into the cord or the spinal membranes or fracture or dislocation in the neighborhood of the lowermost cervical vertebræ was suggested in explanation of the symptoms. Dr. F. A. Packard exhibited "A Case of Enlargement of the Liver and Spleen in a Congenital Syphilitic." The child came frequently under observation for the relief of tonsillitis. The enlargement of the abdominal viscera was thought to represent a condition of amyloid disease. Dr. S. McC. Hamill read a communication entitled "Report of a Case of Heart Disease with Very Much Enlarged Spleen; Autopsy; Demonstration of Specimens." The child originally came under observation with symptoms of mitral insufficiency, to which, in the course of an attack of chorea, those of mitral obstruction became superadded. Death took place suddenly, it was supposed from cerebral embolism, and in addition to verrucose endocarditis and enlargement of the spleen, old infarction of the kidney was found. Dr. Arthur Van Harlingen read a paper entitled "Report of Three Cases of Creeping Larvæ in the Human Skin." Two of these occurred in children and one in an adult.

The lesions consisted in curved and wavy lines of redness and vesicles. They disappeared on incision, although no parasite could be found. Dr. Alfred Hand, Jr., presented a communication entitled "The Positive Diagnosis of Meningitis, Particularly Tuberculosis, by Means of Lumbar Puncture." He pointed out the value of this procedure as a diagnostic aid and the significance of the presence of bacteria and cellular elements in the fluid secured. In some cases improvement followed in the train of the manipulation, and, apparently, as a result thereof.

Obituary Notes.—Dr. MARIE E. ZAKRZEWSKA, the pioneer woman physician of Boston, founder of the New England Hospital for Women and Children, and for nearly forty years a director and physician there, died May 20 at her home in Jamaica Plain, Mass. She was born in Berlin, in 1829. Her great desire to study medicine, which the law forbade her to do at home, led her to come to America in 1853. She took the degree of M.D. from Western Reserve Medical School in 1856. Drs. Elizabeth and Emily Blackwell of New York were among Dr. Zakrzewska's associates in the early days of women doctors.

Major JOHN BROOKE, Surgeon United States Army, retired, died at his residence at Radnor, Pa., on May 12. He was born in Delaware county, Pa., in 1830. He was graduated from the University of Pennsylvania and engaged in private practice until the Civil War. He was appointed assistant surgeon in the Regular Army, November 22, 1862. He served through the Civil War, part of the time in the Army of the Potomac and part of the time in the Columbia College Hospital in Washington. He was breveted Captain and Major in the Regular Army for faithful and meritorious services during the war. After the Civil War he was stationed for many years in the West and was engaged in several Indian campaigns, notably that with the Nez Perces. He was stationed for several years at San Juan Island, and Sitka, Alaska, and was afterward post-surgeon at the Presidio, San Francisco, Fort Monroe, Va., and Fort Leavenworth, Kan. He was retired from active service on February 22, 1894.

Dr. JOHN G. ELLIOT, assistant physician at the Hudson River State Hospital, died suddenly of heart disease. He was thirty-one years old and was from England. He was graduated from the Medical Department of the University of Buffalo in 1897.

Dr. WILLIAM TODD HELMUTH, the leading surgeon in the Homeopathic School of Practice in this country, died at his home in this city on May 14, of angina pectoris. Dr. Helmuth was born in Philadelphia, in 1833, and was educated at St. Timothy's College, Baltimore. His uncle, Dr. W. S. Helmuth, who was one of the first homeopathists in this country, induced him to study that branch of medicine, and he was graduated from the Homeopathic Medical College of Philadelphia in the class of 1853. Soon after graduation he was made professor of anatomy at the Homeopathic College, and published his book, "Surgery and Its Adaption to Homeopathic Practice," which became a textbook for the surgeons of his school. In 1858 he went to St. Louis and helped to establish the Homeopathic Medical College there. He was elected president of the American Institute of Homeopathy in 1867. In 1870 he came to New York. For many years he held the chair of surgery at the New York Homeopathic Medical College and Hospital, and was at one time or another consulting surgeon for every homeopathic hospital in this vicinity. Both the British and French National Medical societies made him a complimentary member. Yale University gave him the degree of LL.D. in 1891.

Correspondence.

OUR LONDON LETTER.

(From Our Special Correspondent.)

UNIVERSITY EDUCATION—RELATION OF MALIGNANT AND RHEUMATIC CARDITIS—DEFECTIVE MORAL CONTROL IN CHILDREN—MEDICAL MISSIONS—MAJOR ROSS—SMALLPOX AND CHILDREN'S EXCURSIONS.

LONDON, May 2, 1902.

THE reorganization of the London University is leading to appeals for endowments on a considerable scale. The institutions which are to be incorporated are also, for the most part, in want of money. An abundant opportunity for the wealthy and generous is therefore afforded of promoting the higher education.

Lord Reay, president of University College, is asking for more than £100,000 for the immediate wants of that college to render incorporation possible, and he plainly states that much more money will eventually be required. To render incorporation fruitful, he computes that a million should be raised. Mr. Waldorf Astor has given £2,000, an old student £30,000, and the Drapers' Company £30,000; and this day a week there is to be a public meeting at the Mansion House, over which the Lord Mayor will preside in support of this appeal. University College is, accordingly, in a fair way of securing her immediate necessities.

But what of the other colleges and educational institutions to be incorporated?

No doubt we shall hear a good deal about their wants before the University fulfils the expectations that have been raised about it.

Connected with this subject is the length of the working terms and vacations at the older universities, about which there has long been controversy.

The Rhodes' bequests to Oxford have directed further attention to the subject, and a number of letters have appeared in the *Times*, advocating modifications. The terms of Oxford and Cambridge amount altogether to twenty-one to twenty-four weeks in a working year. Thus two years of the students' life are occupied in what could easily be accomplished in one, and those intended to be benefited by Mr. Rhodes' bequests, might, many of them, be thereby prevented from taking advantage of his endowments. The old universities would do well to settle the question by arranging their terms to coincide with those of the medical sessions.

The relation of malignant to rheumatic endocarditis has occupied the attention of the Medical and Chirurgical Society for two evenings, and is being widely discussed. At the first, Drs. F. J. Poynton and Alexander Paine communicated the results of their latest research in the department in which they have made such distinct advances. Rheumatic valvulitis being now known to be infective, they think the term "malignant" endocarditis better than "infective," and they conclude, from their researches, that there is a group of cases of malignant endocarditis of rheumatic origin. They offered evidence of this from clinical experience, morbid anatomy and bacteriological and experimental investigations. They isolated from such cases a diplococcus which could be grown in pure culture, which reproduced the disease (in rabbits), and which, in its morphology and cultural characteristics, resembled the diplococcus of acute rheumatism. Further, the diplococcus of rheumatic fever produced malignant endocarditis in rabbits, while this new diplococcus, from some cases of malignant endocarditis, produced rheumatic fever in those animals. Lastly, every grade of valvulitis, from simple to malignant and *vice versa*, may be produced by these two diplococci. These two organisms only differ in the smaller size and more rapid growth of the malignant one. It was possible that their acid-producing properties might play some part in rheumatic processes. Drs. Poynton and Paine do not think rheumatic valvulitis the only manifestation that may become malignant, but suggest that pericarditis and arthritis may, perhaps, do so. In rheumatic valvulitis diplococci were not found in the necrotic tissue, but were numerous in that of malignant endocarditis. A very interesting experiment was the production of rheumatic fever in a rabbit by inoculating it with the diplococcus of rheumatic fever, and some months later malignant endocarditis, by reinoculating with the same organism. This looks as if damaged tissues were less able to resist the attack of the organism. Drs. Poynton and Paine also gave some results of inoculations with the streptococcus pyogenes and dealt with some observations upon septic, rheumatic, and rheumatoid processes. The paper was illustrated with specimens, drawings, and lantern slides.

The discussion on the paper was adjourned to 22d ult., when Drs. W. Ewart and A. S. Morley communicated a paper tending to show the possibility of recovery from the active stage of malignant endocarditis. Cases of recovery [illegible] should be found.

Dr. [illegible]

Dr. [illegible] Drs. Poynton and Paine [illegible]

Dr. [illegible] said that the best paper of Drs. Poynton and Paine was [illegible] suggested that Drs. Poynton and Paine might [illegible]

Dr. Parkes Weber asked whether Drs. Poynton and Paine had met with large white kidneys in their experiments, as he had seen it in a case of endocarditis complicating renal disease, and was inclined to regard it as a result of [illegible] nephritis due to [illegible]. It was [illegible] that [illegible] infarction might [illegible].

Dr. Walker with Dr. Beattie had investigated four cases at Guy's Hospital, and they confirmed the researches of Drs. Poynton and Paine.

Dr. J. H. Drysdale said the diplococcus had many streptococcal characters and we might anticipate that now and then it would become malignant. Possibly rheumatism was not due to a specific organism.

Dr. Blake asked about lumbago, etc.

Dr. Poynton, in reply, admitted that some of the [illegible] might be due to secondary infections, but we had no proof of it. He had met with large white kidneys in a number of the cases. If there were several rheumatic causes, each must admit of proof. In lumbago, etc., there were no [illegible].

Dr. Paine also replied. He said the chief difficulty in experimenting was the large doses required. The diplococcus rheumaticus was more nearly related to the pneumococcus than to the streptococcus pyogenes.

Dr. G. F. Still, whose contributions to pediatrics cannot have escaped your notice, delivered the Goulstonian Lectures this year, taking for his subject some abnormal psychical conditions in children. His chief object, as stated by himself, was to investigate the occurrence in children of morbid mental states, in which only, or chiefly, the moral control is affected, and to determine, as far as possible, under what conditions these morbid defects of moral control arise. Some extremely interesting instances of failure of control were given, and the whole subject treated from a broad point of view. Beyond what the lecturer could bring before his audience arise many social and educational problems that call for earnest consideration. Beyond them again rise thoughts as to what may have been the condition of these morally-defectives in the past and what their sufferings.

The annual meeting of the Medical Missionary Association was held on the 18th inst., when Deputy-Inspector General Saunders, M.D., C.B., presiding, gave interesting reminiscences of the work in which he has long been engaged. The secretary, another veteran in the cause, Dr. T. L. Maxwell, said there was still a want of candidates. There are some 320 qualified medical missionaries from this country at work. It is calculated that nearly two and a half millions of patients are seen annually by medical missionaries, more than 80,000 being in-patients in hospitals established by these self-denying members of the profession.

The Jenner Institute of Preventive Medicine has secured the services of Major Ronald Ross, F.R.S., to direct a department for the study of animal parasites in reference to pathology and epidemiology.

Smallpox continues in the way anticipated. The number of cases has fallen and we may expect this decrease to continue as summer advances, but there is, of course, the fear of recrudescence in autumn. It has been suggested that the summer holidays given to poor children may cause it to be spread in different parts. But, with reasonable pre-[illegible]. No [illegible] child should be [illegible] and the [illegible] that of a [illegible].

A VISIT TO JAPAN FOR HEALTH OR PLEASURE.

(From Our Own Correspondent.)

HAVING [illegible] Japan [illegible] February [illegible] German Lloyd [illegible] arrived in London on April [illegible] Nagasaki, Shanghai, Hongkong, Singapore, [illegible] Aden, Suez, Port Said, Naples, Genoa, Gibraltar, and Southampton. After a very [illegible] voyage of forty-eight days [illegible]. It is with the purpose of [illegible] attention to this very interesting portion [illegible] I would strongly recommend taking a second-class ticket through to Yokohama, [illegible] northern lines of railway, and crossing either from Tacoma, Seattle, or Vancouver to Yokohama. There is no second class, I understand, on the Pacific Mail or Oriental & Occidental lines from San Francisco, but there is fairly good second-class accommodation to be had on the Japanese Yusen Kaisha line from Tacoma and by "intermediate" on the Canadian Pacific from Vancouver. The new boats of the Northern Pacific Railroad may also furnish good second class. From Yokohama the North German Lloyd furnish unequalled second-class accommodation to Southampton, where other fine boats of the same company's trans-Atlantic line will carry the passenger on to New York or other American ports.

The best time of the year to be in Japan is in the spring or autumn, and the same applies to the sea journey between Japan and Europe. If, therefore, the traveler proposes to be in Japan in the autumn and can spare some months there, it would be best to go either direct from the United States, timing it so as to reach Yokohama as early in November as convenient, and remaining there during the chrysanthemum shows and other autumn and winter festivities, going forward by the North German Lloyd or some other line as late in the winter as possible. The better plan would probably be to reverse the order of the journey and leave the United States in February, via Southampton and Gibraltar or London, Paris, Genoa and the Suez Canal, reaching Japan in April, in time for the cherry blossoms. The expenses of travel on shore can be very much economized by stopping at private hotels or pensions, and medical men visiting Japan should provide themselves with introductions to the "Welcome Society" and the *Sei I Kwai* or Society for the Advancement of Medical Science in Japan, of which Kanehuro Takaki, F.R.C.S., and Baron Saneyoshi, Medical Chief of the Navy Medical Bureau, are president and vice-president respectively. Letters to some of the English or American medical practitioners of Tokyo and Yokohama or Kobe should also be procured. Armed with such letters opportunities of visiting medical institutions, such as the Charity, Red Cross and University hospitals, Institute for Infectious Diseases, etc., as well as of learning the ways of otherwise spending the time at disposal to best advantage, will be obtained. Visits to Kamakura, Hakone district, Nikko, Kyoto, Nara, Kobe, points of interest on the inland sea, and Nagasaki will all claim time and reward the traveler's perseverance. If the tourist finds that he is unable to make a round-the-world trip, a visit to Japan alone will well repay the loss of time and the expense, and may be accomplished comfortably in from forty to sixty days from New York, and might be undertaken early in the autumn or spring. Midsummer is usually rather hot, and traveling not so pleasant or comfortable, but if the convenience of the tourist does not permit his coming at any other time, his trip would still prove most enjoyable, the principal drawbacks being the heat, occasional epidemics of dysentery and cholera, [illegible] the plague itself. The months of June and October are usually the most rainy. The clearest bracing weather is from the beginning of November to the middle of January; greatest cold with storms from middle of January to end of February; uncertain weather, mostly cold, in March, and variable weather, with showers, in April and May. Sometimes it is quite hot in May, and hot, damp, sticky weather, with rains, prevails in June. Hot, clear weather (80° to 90°), with occasional storms from the middle of July to the middle of September; typhoons in September, and sometimes earlier. The ascent of Fugiyama, 13,000 feet high, is usually only to be made in August, although tourists do sometimes climb it the month before and after. Otherwise, most of the principal points of interest can be visited at any time of the year.

The remainder of the voyage from Japan to America, via the Suez Canal, is full of interest. We see Shanghai, with its native and foreign cities, Hongkong and Canton, in southern China, Singapore and Penang, with their native towns and the public gardens, giving one some idea of the customs and appearance of the Malays of the islands and mainland, and Colombo, of the mixed races of India, while at Aden the Arab and Africans, and in Egypt the gathering together of the peoples of many European, Asiatic and African lands. Beautiful glimpses of Italian scenery, through the streets of Messina, and up the mainland coasts, with little trips ashore and visits to Pompeii and Herculaneum, and the wonderful museum at Naples; the wonderful Campo Santo, the beautiful gardens, gorgeous churches and public buildings of Genoa, passing views of the Italian and French Riviera, Sardinia, Majorca and Minorca, famous Gibraltar and the coasts of Spain and Portugal. We also got some variety by way of being "rocked in the cradle of the deep" in the Gulf of Lyons, the Bay of Biscay and the English Channel, unless we escape the possibilities of these experiences and go overland through Switzerland and France with only a few hours' discomfort in the English Channel.

The writer is completing his fifth trip round the world during the past twenty-five years, and has found it none the less enjoyable and instructive, and, although not taken by him for the mere purpose of pleasure or rest, but as part of a leave of absence at home, he has found it both pleasurable and exceedingly restful when taken at suitable seasons of the year. This last voyage, for instance, having a record of but three or four stormy days in forty-eight.

THE FUTURE OF THE AMERICAN NEGRO.

To the Editor of the Medical Record.

Sir:—Your editorial in the Medical Record of April 5, commenting on the views of Dr. Seale Harris of Alabama, relative to the health of the American negro, seems to me not to treat the negro side of the case fairly. The misapplication of facts and the sentiment expressed by Dr. Harris show too plainly that he has allowed race prejudice to warp his judgment. Dr. Harris claims that the negro has retrograded physically since the war, resting his belief on the fact that the negro suffers from more diseases now than he did before the war Why is that? I claim that it is due to a change of conditions and not to physical deterioration. In the days of slavery, a negro's chief occupation was farming, and farming is one of the most healthy pursuits man can follow. The farmer gets plenty of fresh air and plain food. But since emancipation the negro has entered nearly every occupation followed by the white man. Is it strange, then, that the diseases incident to such occupations affect the negro? How does it argue deterioration? The negro was not affected with these diseases in slavery, because his occupation as a slave did not expose him to them. It is true that the negro has become a great sufferer from tuberculosis, a disease from which he was practically immune in the days of slavery. But it is because so many have given up farming for city surroundings and indoor occupations. In other words, the negro is more exposed to disease now than before the civil war, and hence the increase in disease among his race. That the negro is deteriorating physically because he is becoming less prolific is poor reasoning. It is an established fact that as man rises in the scale of civilization and intelligence he becomes less prolific, and the negro is no exception to this rule. That the negro has made a wonderful advance in civilization and intelligence no fair-minded person can deny. It is not a retrograde sign that the intelligent negro wife and mother, surrounded by the influences of a civilized home, should have a family of only three or four children. The slave masters used to use the negro women as "breeders," and it was common then for the negro women to have from ten to twenty children.

The fact that the death rate before the war was less among the negroes than the whites is accounted for by the fact that the slaves labored on the farms and lived mainly in the country regions, while the whites lived high and followed an indolent life. Naturally the white death rate was higher. But now the whites labor more on the farms, and otherwise, and the negroes labor less on the farms and have flocked to the cities. Hence, the change in the former death rate. In the country sections there is very little difference in the death rate of the two races; but in the cities of the South the death rate among the negroes is alarming, and, as stated by Dr. Harris, much higher than among the whites. But the cause lies not in physical deterioration, but due largely to the rule of the race which Dr. Harris represents. The whites control the cities absolutely yet it is a notorious fact that the municipal authorities of Southern cities give no attention whatever to the hygienic improvement of the sections in which the negroes live. The negroes have flocked to the cities because of the greater advantages there. Yet, they are forced to live in the most unhealthy portion of the city. The sewerage system is poor, and in many cities the negro sections have no sewers at all. The streets of the negro sections are allowed to remain filthy and dingy. Houses constructed for negro occupation are done so with utter disregard for proper ventilation. The negro sections are seldom provided with parks, and in many cities the police will arrest a negro if caught in the public parks. The hospital service for the treatment of poor negroes is very inadequate. Is there any wonder, then, that the negro is a great sufferer from tuberculosis, typhoid fever and malaria?

American authorities, by hygienic improvements, changed Havana from a pest hole to a flourishing and healthy city. The white authorities can use the same to reduce the death rate among the negroes in Southern cities. Of course, the mass of the Southern negroes need to be educated in the laws of hygiene, because they have not had an opportunity. But the educated and intelligent negro is doing all he can to teach his race in this respect. Proper appreciation and conception of hygiene require intelligence, despite the fact that Dr. Harris deplores the money spent for his mental development. Perhaps, he would have the ignorant negro possess the same intelligence as the educated white man?

Despite all the causes that militate against the negro, there is still a favorable increase in population, according to the census of 1900. Despite "dirt, disease and the devil," with "mob law" thrown in for good measure, the negro population increased from eight million in 1890, to about ten million in 1900. That does not look like extinction.

George E. Cannon, M.D.

Jersey City, April 19.

Progress of Medical Science.

The Boston Medical and Surgical Journal, May 15, 1902.

Traumatic Asphyxia.—H. H. A. Beach and Farrar Cobb report a case of this rare affection, which is characterized by a peculiar and striking discoloration caused by forcible compression of the thorax for some length of time, so that breathing cannot take place. The man was caught and held by an elevator for fully three minutes. His face turned black and his eyes protruded and he bled from the nose before he was released. The skin of the face seemed to be dotted with countless spots from black to reddish black or blue in color, very close together, and between these spots lines or areas of normal skin. The skin was examined microscopically, but appeared to be normal. This is important negative evidence in favor of stasis as the cause of the color; certainly had there been subcutaneous hemorrhage the sections would have shown it.

Amaurosis (Atrophy of the Optic Nerve), and Its Treatment by the Subcutaneous Injection of Strychnine.—Hasket Derby, from his experiences, reaches the following conclusions: (1) Strychnine is a stimulant to the optic nerve. Even in normal eyes it slightly increases the acuteness of vision and widens the visual field. These effects are temporary. (2) In certain cases of optic nerve atrophy its local subcutaneous injection has, to say the least, coincided with an arrest in the progress of the disease, and has been followed by a somewhat increased acuteness of vision. Whether these effects are temporary or permanent, time and fuller statistics will show; (3) In a progressive case of this disease it is clearly our duty to state the above facts to the patient, and allow him to take the treatment if he is so inclined; (4) The strychnine should always be administered in the temple, and by subcutaneous injection.

Angina Cruris (Intermittent Claudication.)—G. L. Walton reports the case of a man who complained of attacks of severe pain in the right calf. He could walk but a very short distance before being seized by a pain which prevented further motion. The attacks last about half a minute, and the blood pressure taken at the onset of one of the attacks showed a rise of 50 mm. of mercury. Atheroma has been regarded as the underlying cause of this affection, also gout, the misuse of tobacco, exposure to cold, etc. Many cases have now been reported be-

[illegible] blood pressure is essential to the [illegible].

Diseases of the Ear of Interest to Insurance Examiners [illegible] Modern surgery has proved that many [illegible] formerly considered hopeless can be [illegible]. In a general way, it can be said that those diseases of the ear which should cause the unconditional rejection of the applicant consist of local manifestations of grave constitutional disorders. Active suppuration should be rejected with the reservation that they may be accepted only when absolutely cured.

Journal of the American Medical Association, May 17, 1902

Grave Abdominal Injuries without External Evidences of Traumatism.—R Harvey Reed reports several such cases, and states that from the literature of the subject and from his own experience it is his conviction that it is the surgeon's duty to make an exploratory incision in all cases where there is grave doubt as to the real nature of the injury, and particularly so when the constitutional symptoms point to a condition more serious than is indicated by either the subjective or objective symptoms, provided the physical condition of the patient is such as to warrant an operative procedure.

A Preliminary Report on the Transmission of Pathogenic Germs by the Common House-Fly.—J Manning has carried on a series of experiments with culture tubes inoculated with various pathogenic organisms taken from patients, flies being confined with the materies morbi and then being allowed to infect the tubes. He finds that molds grow so rapidly on many of the fly-infected tubes that only a few are presentable for inspection, suggesting the possibility that flies are often fungus-ridden, whether transmitting pathogenic germs or not. During the experimentation forty-four culture tubes were subjected to fly infection, of this number forty-one tubes showed colonization at the end of forty-eight hours, three tubes remaining apparently sterile. The following germs were transmitted by flies, and isolated, pure cultures being obtained. Pathogenic germs—bacillus pyocyaneus, staphylococcus pyogenes aureus, bacillus typhi abdominalis, bacillus coli communis. Non-pathogenic—bacillus prodigiosus, sarcinæ aurantia, sarcinæ alba, molds and fungi.

New York Medical Journal, May 17, 1902

Hypnotism, A Useful Aid in the Treatment of the Morphine Habit.—S A Agatston reports the case of a woman of thirty-eight years who was accustomed to take 25 grains of the drug each twenty-four hours. This was gradually reduced within two weeks to half a grain and then within another week to zero. The patient suffered intensely with the usual symptoms, which all the remedies in common use failed to relieve. The author then tried suggestion, instructing the patient to sleep for eight hours, awaking at a certain hour. This plan persisted in each night ultimately led to a perfect cure.

Subcutaneous Injection of Paraffin in the Correction of Nasal Deformities.—Harmon Smith relates his experience with this mode of treatment, which consists in the insertion into the depressed area of the sunken nose of injections of paraffin. The latter should have a melting point of 115° F. An ordinary syringe is filled with the material and kept ready in sterile water at 12[illegible]° F. The area to be filled is anesthetized after preliminary sterilization and the paraffin slowly injected under considerable pressure. It remains plastic for about half a minute during which time the nose is moulded into a proper shape. The result is such as to present a normally shaped organ. It has been found that the material is well borne and remains inert in the tissues. It becomes surrounded with connective tissues and the initial swelling about the seat of injection speedily subsides. [illegible]

Medical News, May 17, 1902

Sclerotomy, Anterior and Posterior, in Glaucoma.—Although Darcy Webster has [illegible] the operation of anterior sclerotomy, he thinks that it ought to be [illegible]. He reports a case of posterior sclerotomy. The patient was [illegible] years old and was suffering from chronic glaucoma [illegible] the patient [illegible] The eyeball was punctured just back of the ciliary region and the incision extended, so that it was about three times as long as a Graefe cataract knife is wide. A few drops of fluid escaped. A bandage was applied and the pain ceased. The eye was washed and rebandaged daily, but no mydriatic or myotic was used. The bandage was used for seventeen days. The result was most gratifying.

Orthopedic Operations for Intractable Cerebrospinal Cord Lesions, with Report of Two Cases.—Homer Gibney advocates operation for cases of unyielding, stubborn, and intractable deformities of cerebrospinal origin, and after correction or overcorrection, the application of suitable apparatus. The first case he reports was a girl of fourteen years. Her gait was ataxic, the spine presenting slight lateral deviation. The patellar reflex was absent. Both feet were held in moderate cavus, the right most marked. The plantar reflex was accentuated. The great toes were flexed at distal phalanx. A long incision was made over the tendo Achillis of the left foot, and the tendon was exposed and lengthened. The edges of sheath, fascia, and skin were sutured. The right tendon was divided subcutaneously, the plantar fascia was severed, and both feet were put up in plaster of Paris at 85°. Locomotion was much improved. The second patient was a man of twenty-six years. His spine was slightly deviated to the right. The patellar reflexes were absent. The left foot was held in marked cavus, with the great toe slighly flexed, trigger shape. The right heel came down well. The left tendo Achillis was divided subcutaneously; the contracted plantar fascia was severed; the great toe was stretched, and the whole foot was put up in overcorrected position. Double uprights, with stop-joint at the ankle, were applied in both of these cases. The second patient was enabled to walk with the foot square on the ground, and far more easily than before the operation.

American Medicine, May 17, 1902

A New Sign in Thoracic Aneurysm (?).—Henry Lee Smith describes this sign, which he has found in each one of the four cases of well-marked thoracic aneurysm which he has recently examined. He thinks there is probability of its constant presence in these cases. The sign is brought out by combined palpation and percussion. The cricoid cartilage is grasped as in tracheal tugging, an assistant percussing the chest. When normal parts are percussed, the palpating hand feels a distant and feeble jar (proximal ends of the clavicles excepted), but so soon as the aneurysmal area is reached, a shock, which is both direct and resilient, is felt, and somewhat suggestive of the sensation experienced when a rubber bag filled with water is simultaneously palpated and percussed. It is well to note if the sign is present when the patient is changed from the erect to the recumbent and lateral positions, and, if possible, the location of the aneurysm itself.

Raynaud's Disease.—Emil King defines this disease as a vasomotor neurosis, dependent on an exaggeration of the excitomotor powers of the central nervous system, causing angiospasm in localized areas in various parts of the body and characterized by three grades of intensity, local syncope, local asphyxia or cyanosis, and local gangrene. Both sexes and all ages may be affected, but it is most often seen in females and young adults. Practically, nothing is known of its etiology. A neurotic temperament and family history seem to act as predisposing factors, and, in addition, the usual causes of arterial degeneration and sclercsis of the central nervous system, syphilis, alcoholism, rheumatism, and unfavorable hygienic conditions. Hysteria, and chronic constipation with autointoxication, may be factors in its causation. In a large proportion of cases the disease appears without premonitory symptoms. It usually affects in order: Fingers, toes, cutaneous areas of the legs and body, the tip of the nose, and the ears. The internal organs probably do not escape. The prognosis is favorable so far as life is concerned. In the young and otherwise healthy patient it is apt to run a mild course and recovery may be permanent. Nothing definite is known of the pathology of the disease. The treatment is very unsatisfactory, and still remains empirical. It depends largely on the physical condition of the patient. The local treatment consists of maintaining an equable temperature in the affected part. The gangrene should be treated in the usual manner. For pain, the usual sedatives are employed.

Vaccination from the Standpoint of the Surgeon.—The following method to obtain a noninfected vaccine sore is described by Ernest J. Mellish: Scrub the part to be inoculated, and an area around it, with alcohol, and allow it to dry throughly before applying the lymph, or scarifying. After the point where the inoculation has been made has become dry, or nearly so, apply a rather thick pledget of sterile cotton; cover it with gauze or muslin, and fasten it in place with narrow strips of adhesive plaster, carried nearly around the arm above and below the scarification. Generally, at the return visit, it can be determined, by merely limiting one side of the dressing, whether the vaccination is taking or not. If it is, and the dressing is dry, no change is necessary. Even if a bit of the cotton has become incorporated with the scab, if the wound is aseptic, it may be left till thoroughly dry, and then the surrounding cotton cut away. Never vaccinate the lower extremities. Serious results sometimes follow. Instead, the wound may be made on or near the shoulder. No physician should vaccinate a person, except in an emergency, unless he is willing to follow the case carefully. Definite instructions should be given about its management if the individual cannot return. Glycerinated lymph is almost unanimously considered efficient in its effects as a protection against smallpox. Only that which is produced by a reliable firm should be used. Everything must be sacrificed to quality. Probably nearly all cases of tetanus following vaccination in recent years became infected after the operation and not at the time of it. No argument is required by one who has studied the facts as to the question of vaccination protecting against smallpox.

The Lancet, May 3, 1902.

The Diagnosis and Treatment of Various Forms of Goiter.—James Berry divides goiters into the following classes: parenchymatous (bilateral), encapsulated (solid and cystic), exophthalmic, and those due to malignant disease. His personal experience is based on 155 operative cases. Among the earlier operations, or, to be strictly correct, among the first forty-six, there were four cases of death. The only death in the last 109 cases was that of a woman who was admitted to the hospital with much cyanosis, a large and partly substernal goiter, and signs of an intrathoracic tumor of uncertain nature. Berry performed an exploratory operation and removed the substernal portion of the goiter. The wound ran a normal aseptic course, but the dyspnœa and cyanosis were not relieved. When the patient died, rather more than three weeks after the operation, it was found that the dyspnœa was due to a sarcomatous tumor of the root of the lung and mediastinum secondary to a small primary growth of the abdomen. This death is also the only one that has occurred in his cases after any enucleation operation, the total number of which is 100.

Note on the Relief of a Distended Joint by the Establishment of Subcutaneous Leakage.—T. Pridgin Teale reports two cases. In the first the preliminary steps of the operation for drainage showed that the fluid knee-joint was synovial in character. Teale, therefore, maneuvered his knife so as to make an opening in the capsule about half an inch in length, in order that the fluid might leak into the surrounding extraarticular tissues, where it was likely to be absorbed. In order to render this process as thorough and rapid as possible, he made three or four other punctures into separate regions of the synovial cavity, taking care that the openings in the skin were not larger than the width of the narrow blade, whilst the capsular openings were about half an inch in length. The result proved to be even better than he dared to hope. The pain ceased, the effusion disappeared, and the joint rapidly recovered. In the second case he made a subcutaneous incision through the capsule of the right hip-joint, so as to establish a leakage, and at the same time divided the tensor vaginæ femoris and the abductor longus tendon, which were tense. The immediate result seemed to be satisfactory. Later the case relapsed and an abscess formed in front of the hip-joint. The head and neck of the bone were, therefore, excised, the head being eroded. In this case there was a temporary arrest of the synovial distress, but the treatment eventually failed, probably because the focus of the disease was beneath the articular surface of the femur.

Scurvy Developing in a Rickety Boy Aged Five and a Half Years.—The case is reported by G. Carpenter, who believes that while certain dietetic errors may predispose to scurvy, there is a personal factor which must not be overlooked even in infants. Infants at the breast have developed scurvy, though this is not a common occurrence. The disease has been observed in new-born infants. Yet fresh breast milk is deemed to be eminently anti-scorbutic and it is certainly free from the ptomaines of decomposition, though in other respects it may be quite unsuitable as a food for the purpose of rearing a healthy child. Undoubtedly many articles of diet which have been administered over long periods of time are capable of producing scurvy in some infants and, equally, undoubtedly, they will not do so in the majority of others. Infantile dietetic errors are the rule, but it is only exceptionally that a case of scurvy comes under observation. It would appear that in infantile scurvy we can go no further at present than to say that the fault lies mainly in the diet, but not from a ptomaine point of view, and the more the food departs from what is natural and the more prolonged is the use of such a faulty food, the more likely is it to produce scurvy. But, for reasons already given, there must be a personal factor in these cases. The diet prescribed may not be appropriate for the particular child for whom it has been designed; certain foods are specially obnoxious to certain children, and of these harmful foods the proprietary foods hold the pride of place.

Some Statistics Regarding the Effect of Inoculation against Typhoid Fever in South Africa.—A. Crombie gives three tables made up from data obtained from soldiers invalided home from South Africa. From these tables the following facts are obtained: Among the forty-six inoculated once there were seven cases in the third month after disembarkation, giving a percentage of 15.2. By the fifth month there had been eleven cases (including seven in the third month, one in the fourth and three in the fifth), giving a progressive percentage of 23.9. In the last column is shown the difference between the incidence of the disease among the not-inoculated and the inoculated. This column shows that the not-inoculated suffered more during the second, third, fourth, and fifth months than the inoculated did; and if those inoculated twice were excluded from the table the advantage would remain with the once inoculated up to and including the sixth month. Subsequently to that time the advantage lies with the not-inoculated, an advantage which at the end of the first year and subsequently amounts to 10 per cent. The following curious facts were also noted: A medical officer found six months after inoculation that his blood gave a well-marked agglutinative reaction. A fortnight afterward he was in bed suffering from enteric fever, showing, as is well known, that the presence of agglutinins is no guarantee of that of alexins. A patient was inoculated twice in February and twice in June, 1897; he was again inoculated twice in February, 1900. In October, 1900, he had an attack of enteric fever in South Africa, followed by a relapse and thrombosis. In May, 1901, he had a second attack of enteric fever, again followed by thrombosis. When his blood was examined in London at the end of 1901 it gave no agglutinative reaction, nor had it any effect on the motility of the bacillus typhosus in six hours. In three or four cases returned in South Africa as simple continued fever a positive Widal reaction was found.

The Lancet, May 10, 1902.

An Interesting Phenomenon Occurring in Tachycardia.—H. D. Everington reports the case of a married woman of thirty-six years with an acute articular rheumatism. During the attack there was an extremely rapid heart action, the beats running at times between 220 and 240 per minute. No evidence of organic disease or of dilatation could be found. If the patient took several deep breaths the rate would drop nearly 100 per minute. Several similar instances are recorded of the effect of deep inspirations in tachycardia, but the author says that as yet no satisfactory explanation of the fact has ever been offered.

[illegible]

The Quiescent or Latent Period in the Course of Grave Abdominal Inflammations.—[illegible] It is this interval of apparent remission in the course of the disease which he terms the quiescent or latent period—quiescent in so far as the disappearance of some of the symptoms is concerned, and latent in that it precedes an aggravation of [illegible] acute peritonitis and a fatal issue. From his personal experience he is inclined to believe that the quiescent or latent period is from time to time a prominent feature in the following group of cases: (1) Injury to the intestines with or without rupture; (2) Perforation of the intestines by ulceration; (3) Injury to, and bruising of, the peritoneal connexions of the viscera with interference with their blood supply; (4) Acute diseases of the genital organs, especially of the Fallopian tubes; (5) Acute appendicitis, either ulcerative, perforating or gangrenous, and this disease, undoubtedly, furnishes the greatest number of cases in this special category.

The British Medical Journal, May 3, 1902.

Ping-Pong Teno-Synovitis.—F. Graham Crookshank reports this case. The patient was a man of heavy build, thirty years of age. There was considerable oedema of the lower third of the left leg obscuring the anterior border of the tibia and acute pain. The swelling was tender and red. The patient was put to bed and examination showed acute teno-synovitis in connection mainly with the tibialis anticus. The patient had been spending much time at ping-pong, which necessitates many sudden alterations in position while the body-weight is supported chiefly on the anterior pier of the [illegible] arch. The strain on the tibialis anticus must be severe. Until costumes and footwear appropriate to the game are worn, these cases will probably not be uncommon.

An Examination of the Fish Hypothesis of Leprosy as Applied to Kashmir.—Ernest F. Neve states that it has been shown that thousands of people have eaten fish in various forms without developing leprosy, which is rarest in the districts of greatest fish consumption. The question of the spread of leprosy is one of great importance in those countries in which the disease is endemic. If acceptance of the fish hypothesis leads us to deal with the matter by aiming alone at the inhibition of unwholesome fish food, then it appears a mischievous theory. If the disease is to be stamped out, the most important measures to be taken are: first, to separate healthy children from their leprous parents as soon as possible; to withdraw lepers from the general community as completely as possible; to use such proper sanitary precautions as shall prevent possible infection or contagion, such for instance as disinfecting dirty clothing by heat before washing, forbidding expectoration on floors or ground, exercising careful supervision over the free ventilation, exposure to sunlight and general cleanliness of the buildings inside and out, and of their surroundings, and of the disposal of dangerous refuse. It is important to regulate the contact of healthy attendants with lepers, bearing in mind the dangers from their clothing and discharges. The disease should be treated as no less infectious than tuberculosis, to which it presents not a few points of resemblance.

A Case of Chloroma.—G. H. Melville Dunlop reports this case, which he believes to be the first in which a diagnosis was made during life. Chloroma is an exceedingly rare condition. The patient was a boy of five years, and was admitted to the hospital complaining of great weakness and swelling of the face. The complexion was very pale, of a waxy yellow tint. A large number of petechial hemorrhages were scattered over various parts of the body. Both eyeballs protruded. The child was deaf. Later, a pale greenish yellow tumor of a jelly-like consistence, developed at the inner canthus of [illegible]

The Signs on the Skin of Certain Common Diseases.—James Galloway first speaks of the [illegible]. These are of various types of [illegible] character and often [illegible] as disorders of the skin appendages. Most of them are of no serious importance. There is another, recurrent type of lesion which resembles in character the various types of erythema multiforme with pruritus. In diabetes there is the general condition which predisposes, and the proximate cause which operates in nearly all cases of skin disorder. The skin of the glycosuric patient is very easily infected by the pyogenic microorganisms. The writer speaks especially of two conditions: Seborrhoeic dermatitis and dermatitis of the genitalia with pruritus. The first lesion is peculiarly common to those patients suffering from the dietetic or so-called "gouty" form of glycosuria. They are usually middle-aged, and often too stout. Warm medicated baths are of great service. In all cases of pruritus of the genitalia and of unexplained irritation or inflammation near the orifice of the urinary meatus, careful examination of the urine should be made. The treatment is often satisfactory. It is most important to control the general the general disease by favorably altering the metabolism and by appropriate diet. The phenazone group of drugs and chloral hydrate are of occasional service. The writer then speaks of lesions of the skin in persons with "low tension" circulation. These persons suffer severely from chilblains, which may ulcerate. [illegible] or reticulated hyperaemia of dependent parts is another condition which occurs. The nutrition should be carefully regulated. This one line of treatment often brings about surprising changes. Warm baths should be frequently taken and warm clothing be worn. Tonics are often indicated.

The British Medical Journal, May 10, 1902.

Case of Prolonged Lactation.—H. R. Clarke and R. S. Nichol report the case of a woman forty-seven years old who was nursing a child five years and two months old. Up to the time that she was seen, the child had been fed at the mother's breast three or four times every day. The mother "always had plenty of milk." It contained nearly as much fat as a specimen of fresh cow's milk with which it was compared. The child was weaned, and after seven days the secretion of milk ceased. During the period of lactation the mother had menstruated only twice.

The Coagulating Power of the Blood in Plague.—Alice M. Corthorn collected, in capsules, blood from thirty-two patients in different stages of plague. In each case the blood was drawn from the finger, sealed in the capsule, and kept in the erect position. Twelve of these patients died within forty-eight hours of the examination, and of these, ten showed absolutely no coagulation at all. The capsules were kept for varying periods up to three weeks, and at no time was a clot observed in them. In some cases, including two of the fatal ones, and several which finally recovered, the clot formation was imperfect. The writer adds that it would be interesting to note how far blood taken from patients in other acute fevers shows this absence of coagulation and the bearing of the sign, when present, on the prognosis and pathology of the disease.

Case of Fatal Anæmia Presenting Some Unusual Blood Changes.—O. K. Williamson and E. W. Martin report this case, which presents some very interesting features. The blood picture, as regards the red blood-corpuscles, is practically that of pernicious anaemia, the diminution in the number of red cells being unusually great even for this disease, being less than one-tenth of the normal number, there being marked poikilocytosis and numerous nucleated cells; the coloring matter, however, being diminished only in proportion to the diminution in number of the red blood-corpuscles. On the other hand, the white corpuscles exhibited, typically, the condition found in lymphatic leukæmia, their number being about four or five times the normal, and consisting of over 99 per cent. of lymphocytes, instead of the normal number of about thirty, the neutrophiles being diminished to about ½ per cent., the normal number being about 70 per cent., and this although the patient was suffering from lobar pneumonia.

On Treatment of Hæmophilia with Calcium Chloride.—C. Edward Wallis describes the history of this case. The patient was a woman of twenty-five years, giving the typical history of hæmophilia. Two months before coming to the writer for advice concerning her teeth, she had had a tooth extracted, with a resulting hemorrhage lasting thirty-six hours. The family history was negative. The girl herself looked very unhealthy. She was more or less a chronic dyspeptic. Her teeth were in a hopeless condition. She was ordered, as a preparatory measure to clearing the mouth, a course of calcium chloride internally. She was to take a mixture containing 10 grains of this salt thrice daily for a week. At the end of this time one tooth was extracted. As long as this treatment was kept up, the results of extraction, which was gradually accomplished, were satisfactory. Leaving the town for a week, she neglected to take the salt, and on the extraction of the next tooth, the hemorrhage, although not alarming, was greater than after any of the other extractions since the treatment had been followed. The dose was then increased to 15 grains, and the results were again most satisfactory. The writer treated another case of hæmophilia in the same manner, with equally gratifying results.

Deutsche medicinische Wochenschrift, April 24, 1902.

The Genesis of Pulmonary Tuberculosis.—H. Ribbert, while not denying that pulmonary tuberculosis often arises directly from the inhalation of tubercle bacilli, maintains that its hæmatogenous origin is more general than is usually supposed. That pulmonary tuberculosis is frequently secondary is amply demonstrated by the large number of phthisical patients, showing the presence of other tuberculous deposits the age of which exceeds that of the pulmonary process. In such instances the primary seat of the tuberculosis is usually the bronchial glands. The age of a tuberculous process must be judged entirely by a histological examination. The mode of infection of the bronchial glands in these cases is of interest. While in certain cases this may take place by extension through the lymphatic system, observation has shown that such is rare. Many facts go to show that the bronchial glands are frequently infected directly from the lungs, no tuberculous lesions being developed at the site of entry of the bacilli. Here the microorganisms are absorbed by the lymphatics directly from the lungs and find lodgement in the bronchial glands, from whence a secondary pulmonary tuberculosis subsequently develops, which is consequently hæmatogenous in origin. Such a hæmatogenous tuberculosis develops by preference at the pulmonary apices and cannot be anatomically differentiated from a tuberculosis directly due to the inhalation of tubercle bacilli.

Berliner klinische Wochenschrift, April 28, 1902.

Treatment of Pharyngitis Granulosa and Lateralis.—Max Halle says that cases of granular pharyngitis which show no destruction of tissue require simply general treatment. Such cases, however, are rare, and in the majority of instances local treatment is necessary. In mild cases the local application of Mandl's solution or any of the astringents is often followed by good results. When these measures are without avail, the use of escharotics, such as chronic acid, trichloracetic acid, or various silver preparations, is indicated; light cauterization with the galvanocautery may also be advantageously employed. When marked pathological changes are present more radical measures are necessary and often times a considerable amount of tissue must be removed. For this purpose the author has devised an instrument known as "throat scissors;" these are made of several shapes, each of which finds use according to the location of the tissue which is to be removed. The employment of these scissors is much to be preferred to *severe* galvanocauterization. Very little pain or reaction follows their use, and the throat wounds heal much more quickly than after galvanocauterization.

Polyneuritis Following Malaria.—A. M. Luzzatto reports the case of a laborer, thirty-one years of age, who gave a history of malarial attacks continuing from October to December, 1900. In January, 1901, the patient developed symptoms of a polyneuritis, and first came under the observations of the author. The spleen was somewhat enlarged, but a search for the malarial organism was negative. The polyneuritis increased in severity and ran a characteristic clinical course, marked muscular atrophy being present. Death occurred on March 3, 1901, from a complicating lobar pneumonia. At autopsy lesions characteristic of a chronic malaria were found in the spleen, liver, and nervous system, but no malarial organisms could be demonstrated. The diagnosis of malaria is certain on the basis of the history and pathological lesions. In the absence of any other cause it seems certain that the malaria stands in direct etiological relation to the polyneuritis. The lesions of the latter were parenchymatous in nature, but not so far advanced as those present in some other cases of malarial polyneuritis which have been reported by Sacquepee and Dopter. This is to be accounted for by the early fatal ending of the present case. Lesions were also present in the anterior horns of the cord, but they were in all probability secondary to those of the peripheral nerves, since they were much less extensive than the changes found in the latter structures.

Münchener medicinische Wochenschrift, April 29, 1902.

A Peculiar Varicella Eruption.—Rudolf v. Hoesslin reports a case of chickenpox in which a peculiar necrosis was present in many of the cutaneous lesions. This necrosis chiefly involved the center of the vesicles, which were surrounded by an extensive zone of inflammation. About twenty such lesions were present, the remaining vesicles being typical of this disease. The general symptoms were not influenced by this peculiar eruption. The necrotic lesions healed much more slowly than the typical varicella eruption. The cause of the necrosis is doubtful, but it was, probably, due to a mixed cutaneous bacterial infection.

Recurrent Herpes of the Male Urethra.—Bettmann reports a case of recurrent herpes of the male urethra, which occurred in a patient who had contracted syphilis a year and a half previously. The first manifestation of the herpes was a urethral discharge. Slight burning was present on urination. A search for the gonococcus was negative. In three days the symptoms entirely vanished without treatment. Similar attacks recurred at from three to six weeks interval. Some of the attacks were accompanied by a typical herpes præputialis. Endoscopic examination during the attacks showed characteristic herpes lesions in the urethra as described by Fournier. The local use of mercury aggravated the attacks and plainly irritated the herpetic lesions. In consideration of these facts, it is certain that the diagnosis of recurrent herpes was sound.

Treatment of Lead Colic with Atropine.—Adolf Weber reports the treatment of several cases of lead colic by atropine. The symptoms rapidly subsided under doses of gr. ¼ (.015) every four or six hours. In all the cases opium had been previously administered, but without beneficial result. Smaller doses of atropine were at first given, but these were unsuccessful. This, as well as the toleration of the large doses of atropine, is to be accounted for by the opium which had at first been given. The origin of the poisoning in these cases is interesting. In the first group the symptoms were caused by drinking water, which had been conveyed through lead pipes. In the second group the source of the lead was traced to flour which had been used by several families for baking purposes. In all of the families which used this particular lot of flour, cases of lead poisoning developed.

The Significance of Small Variations of Atmospheric Pressure for the Human Organism.—O. Rosenbach thinks that the human organism is remarkably susceptible to small variations in the atmospheric pressure. This may be demonstrated by the use of the variometer of v. Hefner-Alteneck. This instrument registers variations in the atmospheric pressure which are exceedingly small and to which the barometer is not sensible. Such variations are constantly occurring in the interior of dwellings, although they are more marked under some meteorological conditions than under others. It is certain that the skin is sensible to these variations in atmospheric pressure, and that the relations of the peripheral and internal circulation may be perceptibly influenced thereby. Certain individuals are especially susceptible in this respect. It is thought that the great tendency of some persons to contract "colds" may be thus accounted for.

French and Italian Journals.

A Case of Peritonitis Propagated Without Perforation During the Course of Typhoid Fever.—M. Vernon and M. Busquet report the case of a young soldier who died of peritonitis, complicating typhoid fever. At the autopsy not the smallest perforation of the intestines could be found. Eberth's bacillus was found in the peritoneal [illegible] April, 1902.

The Supposed Descent of the Heart in the Erect Position.—[illegible]

The Existence in Horses of a Disease of the Bones Analogous to Paget's Disease.—J. Dor, having had occasion to examine some diseased bones of a horse which had suffered from "bran disease" (so called because it is supposed to be caused by the bran which is substituted for oats in the horse's dietary), was struck with the resemblance of the lesions to those of Paget's disease. In both affections there are hypertrophic osseous lesions scattered over the whole skeleton, but especially on the long bones, these lesions being macroscopically and microscopically similar. In Paget's disease the [illegible] process is localized on the maxillary bones, in bran disease on the cranium, and in Paget's it appears at a slightly earlier age and is of more rapid development. That the two diseases are identical the author does not venture to affirm, but he considers the question of sufficient interest to merit further study.—*Revue de Chirurgie*, April 10, 1902.

Human Odors.—Charles Féré calls attention to the fact that the skin possesses a certain odor which varies according to the individual, the age, and the race. The nervous system seems to exert much influence over the odor of the cutaneous secretions. Hammond cites the case of a woman who always gave out an odor of pineapple when she was in a temper, and another who smelt of violets when suffering from an hysterical attack. The special point to which the writer desires to call attention, is that certain odors are inherited, or may even extend to side branches of the same family. Dogs are always able to recognize this odor even when it is so subtle as to escape the observation of man. The author cites interesting cases of emotions produced by odors reminiscent of [illegible] events, and a case of total disappearance of all [illegible] odor with every beginning of pregnancy. In relation to the latter occurrence, he states that [illegible] perfume a half [illegible] after the artificial application of [illegible] their perfume for a much longer time.—[illegible] *Médecine*, April [illegible], 1902.

A Case of Trigger-Finger.—A. [illegible] Clar[illegible] reports a case of this very rare affection. It consists in a peculiar condition of some finger, which is to all appearance normal, but which cannot be freely flexed nor extended. The motion stops at a certain point and can go no farther without special effort or external aid—the last part of the movement is then accomplished with a sudden jerk like the snap of a trigger. Many theories have been held in regard to the causation of this affection, but the generally accepted view at the present time is that there is some lesion of the tendon or of its sheath, or both. Rheumatism, traumatism, and work causing especial strain or long continued fatigue of a certain finger, are the irritating causes. Sometimes the morbid process is cured spontaneously; in other cases it resists all treatment by massage, electricity, the tincture of iodine, etc., and surgical intervention becomes necessary. This consists of incision or excision of the affected part of the tendinous sheath; after the operation the finger is not long immobilized and massage is early applied. Recovery is usually complete.—*La Riforma Medica*, April 17, 1902.

The Edinburg Medical Journal, April, 1902.

Chylous Ascites due to Peritoneal Carcinoma.—A patient of R. Murray Leslie, a woman of fifty-two years, suffered from chylous ascites. At autopsy a large carcinomatous mass was found involving the whole of the omentum, and extending between the coils of the intestine, which were inextricably matted together. The malignant mass was closely adherent to the right lobe of the liver, where it was continuous with a rounded cancerous growth just to the right of the portal fissure and involving the gall-bladder. [illegible]

Some Observations on the Pathogeny and Treatment of Pes Cavus, etc.—J. Jackson Clarke describes a case in which [illegible] The patient can now walk about in comfort. An illustration shows the great improvement in the condition of the foot.

Contracted Bladder Treated by Gradual Fluid Dilatation.—A. W. Mayo Robson describes the case of a woman whose bladder was contracted to about the size of a walnut, and was lined with phosphatic concretions. These were scraped away, after which the bladder was found to have a capacity of only half an ounce. After the operation the bladder was washed out daily with boracic lotion, on each occasion the urethra being compressed around the nozzle of the syringe, moderate force being used in order to increase the vesical capacity. After a few days the incontinence ceased, and the patient was told to hold her urine as long as possible. She could at first hold it for only half an hour, but in three months she could hold 8 oz. of urine without discomfort; her general health was good and the urine normal. In order to keep the urine aseptic while undertaking any operation on the urinary passages, the author usually orders the patient to take boracic acid or salol internally. This practice does much to abolish post-operative urinary fever.

Latent Pneumonia.—Harvey Littlejohn concludes that pneumonia may be completely latent during its whole course, the form most liable to latency being basal lobar pneumonia. Alcoholic apical pneumonia is rarely latent during its whole course. The disease may be latent even though the whole of one lung or a considerable portion of both lungs is affected. This condition is practically confined to persons addicted to excessive alcoholic intemperance. The explanation of latency is to be found in the quantity of alcohol consumed after the onset of the disease, which makes the ordinary signs and symptoms [illegible], and also exerts a stimulating effect, thus enabling the person to go about until he suddenly collapses and dies. In medicolegal cases the discovery of latent pneumonia may satisfactorily explain the death of an individual, and thus allay all suspicion connected with the case. On the other hand the existence of pneumonia, even in an advanced stage, will not preclude the possibility of an individual having died from other causes, natural or violent, and of his having been at the time of receiving an injury in a state of apparent good health.

Diagnosis of Locomotor Ataxia.—E. J. Brown states that locomotor ataxia is one of the most common of the chronic nerve diseases. It is often unrecognized for years, although the most easily recognized of all cerebrospinal nerve lesions. To avoid overlooking this disease, examine every patient with symptoms of whatever nature for the knee-jerk and the pupil reaction; if both exists the patient has no tabes. Examine further for evidence of tabes in any patient showing the following symptoms: difficulty in walking, especially in the dark. Gradual failure of vision or a transient squint. Lancinating pains, or neuralgic pains in legs (sciatica, chronic rheumatism). Sudden attacks of gastric pain, or causeless vomiting, or "bilious attacks" frequently repeated. Difficult or urgent urination ("bladder disease"), incontinence of urine or fæces, numbness of anal region. Diminution or failure of sexual power. A sluggish ulcer on foot or leg. A large painless swelling of a joint. Spontaneous fracture of a long bone or a fracture from some trivial cause. Numbness of one or both little fingers or of ulnar sides of forearm.—*Medical Fortnightly.*

Society Reports.

THE AMERICAN THERAPEUTIC SOCIETY.

Third Annual Meeting, Held in New York City, May 13, 14 and 15, 1902.

REYNOLD W. WILCOX, M.D., OF NEW YORK, PRESIDENT.

FIRST DAY—TUESDAY, MAY 13.

THE meeting was called to order by the president, Dr. R. W. WILCOX of New York, in the New York Academy of Medicine.

An address of welcome was given by Dr. THOMAS E. SATTERTHWAITE.

President's Address.—Dr. REYNOLD W. WILCOX of New York delivered this address, and in it reviewed the progress of therapeutics for the past twelve months.

Valvular Diseases of the Heart.—The following symposium on this subject was presented:

Etiology and Symptomatology.—Dr. THOMAS E. SATTERTHWAITE of New York read this paper. He said that mitral disease was the most common form of valvular affection. Many young men training for athletic contests develop mitral insufficiency. It was often a temporary condition, which would mend with rest. The diagnosis of mitral insufficiency was comparatively easy, there being three cardinal signs, viz.: (1) The murmur at the apex, conveyed to the left; (2) The accentuation of the pulmonic sound, and (3) Increased dulness transversely.

Mitral stenosis and insufficiency very frequently coexist. The diagnosis of the former was beset with difficulties; indeed, in 70 per cent. of his own cases the murmur was not heard at all. Certainly, in 15 per cent. a presystolic murmur would be heard, and in 25 per cent. additional some other murmur would be heard in the diastolic interval. The maximum intensity was usually found at the fourth space on the left side. The bruit of mitral stenosis was of short duration, was not transmitted to a distance, and in, perhaps, half of the cases ran up into the first sound. According to his own experience, a thrill was observed in from 10 to 25 per cent.

Aortic disease was less common than mitral, and insufficiency of the aortic valve was the more common. When the condition was well established the apex would be found depressed and to the left. A diastolic murmur was heard clearly in the second left interspace and was propagated downward toward the apex, so that sometimes its area of greatest intensity was near the base of the ensiform cartilage. In his cases aortic insufficiency had been recognized during life in 62 per cent. There was, however, great difficulty in distinguishing between aortic insufficiency and aortic aneurysm.

Acute aortic obstruction was comparatively common in connection with valvular disease, but as a single lesion it was very rare. He had been unable to find more than one dozen well-authenticated cases of this kind in the literature.

Well pronounced tricuspid affections were comparatively rare. Tricuspid insufficiency was not often met with during life, owing to the difficulty of detecting the murmur, and also to the fact that the tricuspid valve was thought to be of secondary importance. The most distinctive sign was the systolic murmur heard over the lower half of the sternum, and with great intensity usually at the fourth left interspace close to the sternum. The murmur also extended to the right of the sternum, sometimes even toward the right axilla. Epigastric pulsation, when present, was important. The second sound of the heart was often very weak in these cases. Tricuspid stenosis was very uncommon. A point of considerable diagnostic importance was that it was a woman's disease *par excellence.* Out of 164 cases on record the diagnosis had apparently only been made in six instances.

Of all the cardiac valves the pulmonary was the least often affected, and exceptionally it was a single affection. The apex of the heart was displaced to the left in about 20 per cent. of the cases, and in about 25 per cent. a double murmur was audible, which was intensified on inspiration. Pulmonary obstruction was rarely acquired, though congenital obstruction was comparatively common. In the congenital form there was usually stenosis and a lack of physical and mental development.

Treatment.—Dr. T. L. COLEY of Philadelphia took up this topic. He said that important questions to settle at the outset were with regard to the age of the patient, whether the condition was congenital or acquired, the nature of the affection causing the cardiac disease, the condition of the pericardium and endocardium as well as of the myocardium. The same general principles must govern the treatment of all forms of valvular disease of the heart. The examination of the blood often afforded useful hints. The indications for the use of digitalis were much more restricted now than formerly. He considered the present routine use of strychnine most unfortunate, because this drug should be reserved for emergencies. Moreover, while strychnine is a muscle tonic when given in small doses for a short time, tolerance was soon established. The prime indication in the treatment of heart disease was for prolonged rest. Next in importance to this came attention to the diet and assimilation. The modern treatment of heart disease by exercise was based on the idea of producing compensatory hypertrophy, and it was an excellent method, provided there was no marked fatty degeneration; if, however, the myocardium was extensively degenerated this treatment was fraught with danger.

Dr. WILLIAM HENRY PORTER of New York thought the treatment of valvular disease of the heart resolved itself into the recognition of the fact that one had to deal with an organ which is mechanically defective, and that the main thing to be accomplished was to cause an augmented nutritive activity of the muscle tissue. In this way the mechanical defect could be very largely overcome. To accomplish this, one should bear in mind that the work of the heart should be diminished by prolonged rest. He rarely, if ever, used the digitalis series in the treatment of cardiac disease, for the reason that he believed this drug cut off the nutrition of the heart and called upon the muscle fibers of the heart to do more work. When high blood tension was produced the blood was driven through the capillaries so rapidly that there was not sufficient time for the proper molecular interchange between the blood and the muscle fibers of the heart; in other words, these muscle fibers were progressively starved under the administration of digitalis. The only condition in which he used digitalis was when there was a decided overcharging of the veins and a decided underfilling of the arterioles. When this condition was present the use of digitalis would shift the blood from the venous to the arterial side. The remedies which he depended upon most were strychnine, caffein and camphor. Strychnine stimulated the motor impulses emanating from the spinal centers and brought the whole circulatory apparatus into a more nearly physiological condition. He had used strychnine in pretty large doses, and had continued it for years with only good effects; he had yet to see any ill effects from the use of this drug. He reserved caffein and camphor for emergencies. They could, indeed, be used very freely. These remedies were the best he had ever employed in heart disease for producing a physiological hypertrophy of the heart and maintaining a proper state of nutrition.

Dr. ALBERT C. BARNES of Philadelphia said that about seven years ago he had reported a series of observations made by him on the diagnosis of diseases of the heart. In the published description of this research the point was made that the diagnosis of heart disease was not dependent upon any one physical sign, but rather upon a recognition of the condition of the heart muscle, the pulse and the general health. Many presystolic murmurs at the aortic orifice had been proved to be the result of vibratory con-history of the trouble was [illegible] indicative of disease of this organ. Some patients could be made to develop a [illegible] murmur by exercise. He wished to [illegible] with Dr. [illegible] on the [illegible]. It would be well to understand with Dr. [illegible] [illegible] to be preferred to digitalis. It had been demonstrated that so far as their action on the heart was concerned, caffeine and digitalis [illegible]. One of the chief actions of caffeine was upon the [illegible], with its secondary effect also upon the vasomotor centers and [illegible] in an increase in the blood pressure. Regarding the [illegible] of [illegible], the speaker said that he had employed it a good [illegible] to determine the nature of diuresis. It had long been known that theobromine was probably the purest diuretic of all the [illegible], but it was insoluble and irritating. Combined with sodium salicylate, it had been used quite extensively. About two years ago he had made a series of double salts of theobromine with various acids, and had found that the citrate, acetate, and tartrate were soluble salts possessing powerful diuretic action.

Prognosis.—Dr. Leonard Weber of New York read this paper. According to his experience the prognosis in valvular lesions depended principally upon the local and general conditions. It was well not to ignore some of the subjective symptoms, such as pain, shortness of breath, dry cough, and palpitation. One could learn from inspection how much hypertrophy and dilatation were present, and which side of the heart was affected. A reliable and practical method of differentiating between functional and serious organic lesions was the effect upon the pulse of walking rapidly around the physician's office. Such exercise would of course greatly accelerate the pulse, but if the pulse-rate returned to the normal in the course of a very few minutes one could be sure that there was no serious disease of the heart. A very important prognostic sign, dependent upon back pressure, was a passive enlargement of the liver, particularly the left lobe. He had never known a patient with advanced mitral stenosis to live very long after beginning to spit up blood. With the increase of the bulk of the heart muscle there was invariably a lengthening of the first sound of the heart. When the first sound became short and the second sound accentuated, one knew that the heart muscle was failing. If after exercise the heart became arhythmic and did not return to the normal within a few minutes, one might be sure that there was something wrong with the heart muscle; the mere rapidity of the pulse was a secondary matter. His experience had taught him that well established chronic mitral regurgitation gave the worst prognosis as to life, and next to this came mitral stenosis, when it was progressive. The typical presystolic murmur could be closely simulated by pronouncing the word "[illegible]" and in doing so rolling the "r." When back pressure symptoms were present in mitral stenosis, the prognosis was just as bad as in mitral regurgitation. A moderate degree of aortic stenosis, provided it was not associated with pulmonary disease, was indicative of a fairly good prognosis. He had not been able to satisfy himself that aortic incompetency gave a bad prognosis. If there were no complications in the pulmonary or peripheral arteries the prognosis was [illegible] as bad as in mitral regurgitation and stenosis. In practice, the difficulty did not so much lie in estimating the prognosis in these valvular lesions separately as in striking a balance in the combined lesions. Time and observation would often clear up an obscure case.

Dr. Oliver T. Osborne of New Haven said that he had been in a position to see a good many murmurs developing in college students who had undertaken athletic sports for which they were not fitted. As a rule these murmurs would disappear under appropriate rest and building up of the health. Persons with complete cardiac compensation should be told the nature of their disease and advised to regulate their habits of life and diet accordingly. In his opinion digitalis was the greatest of all cardiac tonics where there was lack of compensation. If the [illegible] should certainly not be pushed, if, on the other hand, there was arteriosclerosis or aortic lesions, [illegible], digitalis was certainly contraindicated. In other cases if the heart were made to contract a little more forcibly the nutrition of the heart muscle would be improved just as it was by appropriate exercise. Digitalis had been so much abused that some physicians were discarding it altogether. This remedy was [illegible] so slowly that probably its best action would be evoked by giving it only twice in the twenty-four hours, and in many cases it was well to combine it with nitroglycerin. During acute cardiac dyspnea nothing would do any good which was introduced into the stomach. A most excellent cardiac stimulant was a saturated solution of camphor in olive oil. It acted quickly and very effectively, and he had never known its subcutaneous use to cause abscess.

The Capillary Area.—Dr. Eli H. Long of Buffalo was the author of this paper. He said that the regulating function of the arterioles was most important at all ages, but its conservation as age advanced was not surpassed by any other matter claiming our skill. A person showing the least danger of failure in cell nutrition should have his diet and mental work restricted, he should have an abundance of rest and recreation, and the excretory functions should be kept active. The daily cold bath acted as a valuable tonic to the body metabolism. In the advanced stages the vasodilators were useful, though they could not be looked upon as tonics. Here the carbonated baths proved beneficial.

Dr. Satterthwaite thought the treatment of cardiac disease might be epitomized in the statement that our efforts must be directed toward the treatment of the capillary circulation. In his opinion digitalis was a dangerous drug to use in cases of fatty heart and in rheumatic conditions of the heart. He believed that strychnia should not be given continuously for more than two weeks at a time, but it could then be followed by arsenic with almost equally good results. It was most important to remember that digitalis required hours to produce its effect, and that therefore it was a waste of precious time to use it in emergency cases. The Schott treatment was not suited for cases of arteriosclerosis because of the exercises. The baths themselves were not dangerous, but they should not be given when there was much sugar or albumin in the urine.

The Proper Introduction of Therapeutic Agents to Science and Commerce.—Dr. F. E. Stewart of East Orange, N. J., read a very suggestive paper on this topic, purporting to be a conversation between a drug manufacturer, an ethical physician, a pharmacist and a lawyer. The point made by the lawyer was that all products were the property of the public unless the government saw fit to protect them for a limited period by a patent. The paper was a very strong argument in favor of the pharmacopœia and a plea for its hearty and more general support by physicians and pharmacists. The medical profession had been so negligent in this matter that it had become a stepping-stone for the introduction of many new nostrums.

Proposition for a National Bureau of Materia Medica.—Dr. A. C. Barnes said that Dr. Stewart had done an excellent service in advocating a national bureau of materia medica, which would supply the profession with reliable information, and would rid physicians of much annoyance now inflicted by the nostrum vendors.

SECOND DAY—WEDNESDAY, MAY 14.

Therapeutics of Chromium Sulphate (Green Chromic Sulphate).—Dr. Louis Kolipinski of Washington, D. C., was the author of the paper. He said that from its chemical constitution, chromium should possess therapeutic properties similar to those of zinc and manganese. His experiments in this line had been with the green chromium sulphate. The dose was one to four grains, three times a day, and it was best administered as a tablet triturate. It was useful in that form of cirrhosis of the breast found in aged single women, and also in the sexual impotence of males. It exerted a distinct controlling influence over the flushing and other nervous phenomena associated with both the natural and the artificially induced menopause. The author also thought he had found this remedy useful in a great variety of nervous diseases.

Treatment of Pulmonary Tuberculosis.—A symposium on this subject was presented as follows:

Climatic.—Dr. George Edward Tyler of Denver, Colo., discussed this topic. He said that the essential features of the climatic or fresh-air treatment of this disease were pure air, little humidity, abundant sunshine low wind velocity and low atmospheric pressure. Other things being equal, that climate was the best which had the largest amount of sunshine. The reason for the beneficial effect of high altitude was not yet clear, yet the clinical fact was indisputable. That temperature should be chosen in which the patient found out-door life the most comfortable, though after the patient had become to a certain extent hardened by exposure a cool climate was desirable. The author had prepared a table embodying a study of the statistics obtained from sixteen stations of the U. S. Weather Bureau, situated in widely distant parts of this country. Attention was especially directed to the fact that there was no direct relation between relative humidity and precipitation. From the statistics presented it was shown that the Rocky Mountain range possessed the least density of population, slight humidity, low precipitation, little wind, and almost an entire absence of fog and a large amount of sunshine. The neurasthenic and the excitable do not do well in such a stimulating atmosphere. Persons with active cavities were nearly always positively harmed by residence in high altitudes, and the same was true of those having valvular heart disease. Cases showing the very slightest physical signs and tubercle bacilli, but no elastic tissue, were usually benefited and often cured by a proper selection of climate. Hemorrhage was not a contraindication to high altitudes, unless it meant the presence of a large active cavity, yet it was his conviction that pulmonary hemorrhage was more often fatal in those living in high altitudes. The question of homesickness should receive careful consideration before sending a person away from home, and the same was true of the financial condition of the patient. While consumption was a disease of the poor, it should be remembered that none but the rich could afford it.

Medical.—Dr. Jesse Shoup of Washington, D. C., discussed this subject. He said that the different general blood tonics of service in this disease were iron, arsenic, strychnine, phosphorus and the vegetable tonics. Of the bactericidal class, creosote was, perhaps, the most important, and there could be no doubt that under its judicious administration the fever, cough and expectoration diminish. It was too disagreeable and painful when given by inunction. He had found guaiacol carbonate and the valerianate of guaiacol useful. Dr. S. Solis Cohen was an ardent advocate of the internal administraton of ichthyol, and others had reported favorably upon it, but, personally, he had found its administration exceedingly disagreeable to the patient, and its efficacy founded apparently on the contained sulphur. A third group of medicines was those which stimulate phagocytosis. Intravenous injections of cinnamic acid in glycerine emulsion had been given, and it had also been used subcutaneously, but it had been found a painful and very troublesome method of treatment. Recently, Dr. Shoup said, he had observed beneficial results from the use of 1-10 of a grain of arsenious acid twice daily, and 3-10 of a grain of cinnamic acid in early cases, and in chronic ones free from mixed infection, but in the acute cases this medication seemed to aggravate the disease. Klebs considered tuberculin T. R. almost a specific, and the speaker was of the opinion that it was a valuable adjunct to other treatment in suitable cases. For indigestion and gastric distress he had found nothing better than dilute hydrochloric acid with strychnine and thymol or menthol. Fever was best treated by rest and cold sponging. Night sweats were best treated by cold baths or sponging with cold water or alcohol and menthol, though in some instances the internal use of atropine was demanded. For the relief of the cough codein was very useful, or a tablet composed of cocaine, menthol and codein. His treatment of hemorrhages consisted in absolute rest and quiet, the local use of ice and the internal or hypodermic administration of morphine and hydrastin. It was of the greatest importance that the physician should see his patients at short intervals, preferably every day.

Dietetic.—Dr. William Henry Porter read this paper. He said that it had been demonstrated that the animal class of foodstuffs were easily digested and furnished the highest percentage of nutritive pabulum with the least exertion of the digestive organs. If the requisite amount of albumin were obtained by a proper arrangement of vegetable diet, a large excess of starch and sugar and a deficiency of fat would result. These ingredients were very much more evenly balanced in the animal foodstuffs, but there was a deficiency of the iron-bearing compounds or nucleoalbumin. The two classes of foodstuffs should, therefore, be mixed, the animal predominating. In addition to easy digestibility one must secure the requisite production of heat and energy. The over-production of heat was less detrimental than the overtaxing of the oxygenating capacity of the system. The true cause of imperfect oxidation appeared to be the ingestion of a larger amount of the albumins, sugars and fats than the system could utilize. The author's dietary, based on the foregoing facts, is as follows: 198 grm. wheat bread, 102 grm. eggs, 680 grm. of milk and 512 grm. of meat; a total of 1,492 grm. or 52 ounces, which is divided up into three meals. In tuberculosis it was almost impossible for the system to digest, absorb and utilize the necessary amount of food, yet the overcharging of the system with fats and alcoholic preparations only aggravated the condition. The author was of the opinion that a predisposition to tuberculosis was inherited; that the disease, after being acquired, could be fed out of the system in the manner indicated, and that the more general adoption of a meat diet by the American people in the past decade was responsible for the decrease in pulmonary tuberculosis.

Dr. Olin Leech of Washington, D. C., also made some remarks on this subject. He said that in the matter of feeding each case was a law unto itself, although the same general diet must be the starting point for all. Change of air with enforced rest, such as was secured by an ocean voyage, often increased the appetite most satisfactorily. The early nausea and vomiting was often relieved by the aerated waters or by the use of creosote and lime water, and in the more severe cases, a useful tablet was one composed of two grains each of bismuth subnitrate and oxalate of cerium and $\frac{1}{12}$ of a grain of the muriate of cocaine. A tuberculous patient should have plenty of good, juicy red meat, lightly broiled or scraped, fresh fish, eggs, milk, buttermilk, kumyss, coffee in moderation and an abundance of fresh water. Spinach, asparagus, cresses, lettuce, celery with mayonnaise dressing or pure Lucca olive oil on the salads were allowable, the salads being particularly useful as appetizers. Farina, sago, tapioca, custard and thoroughly ripe fruits might be allowed. Salt fish, pork, hashes and gravies must be avoided.

Physical.—Dr. Egbert Le Fevre of New York discussed this phase of the subject, more particularly the theories that had been promulgated to explain the vulnerability of the apex of the lung to tuberculosis. He advised that the development of the upper portion of the chest in children be watched by the physician, and, if necessary, that respiratory exercises be prescribed. In the second stage, by well-directed respiratory exercises, the arrest of the disease could be aided. He thought the pneumatic cabinet had a sphere of usefulness, but a limited one, and that its use required great judgment.

Dr. T. L. Coley of Philadelphia spoke of the comparatively new formalin treatment of pulmonary tuberculosis, which was based on the view that the whole danger from this disease was from secondary infection. Good reports had come from Italy, but the method, which consisted in the constant wearing of a mask wetted with formalin, was hardly applicable to hospital practice in this country.

Dr. A. C. Barnes of Philadelphia objected to Dr. Porter's paper on the ground that it was largely theoretical. It was founded on the basis of nitrogen as a food element, whereas it was known that such was no criterion of dietetic value.

Dr. Eli H. Long of Buffalo spoke in favor of the inhalation treatment of early cases of pulmonary tuberculosis. He had used with much satisfaction such antiseptics as carbolic acid, tincture of iodine and the compound tincture of benzoin inhaled frequently in conjunction with steam.

Dr. Noble P. Barnes of Washington, D. C., said that it had been demonstrated, experimentally, that infection with tuberculosis could take place through the sperm and also through the ovum and placenta, although ordinarily a predisposition alone was transmitted by inheritance.

Dr. Robert Reyburn of Washington, D. C., said that an important means of preventing tuberculosis in children was by proper attention to the nose, pharynx and tonsils. His observations had led him to believe that tuberculin was a very dangerous agent. The fact that in three-fourths of the autopsies on old persons old and healed tuberculous processes are found showed the probable danger of lighting up anew such a process by the use of tuberculin.

A Contribution to the Therapeutics of Iron and Silver.—Dr. Albert C. Barnes of Philadelphia read this paper, which was the result of a research in this field. (See page 814.)

The Causes, Prevention and Treatment of Puerperal Eclampsia.—Dr. Robert Reyburn of Washington, D. C., read this paper. He considered the cause to be a retention of waste materials, arising from deficient metabolism, particularly of nitrogenous food, lack of exercise, and inactivity of the skin. The principles of prophylaxis were obvious. The curative treatment at full term was rapid emptying of the uterus, and if necessary, venesection. In the earlier months he would advise trying every method of favoring elimination before resorting to the induction of premature labor.

Dr. Matthew D. Mann of Buffalo urged the use of veratrum viride hypodermically in doses sufficient to keep the pulse down to 60. Venesection, followed by the intravenous injection of saline solution, was often most valuable. In the cases coming on after labor he gave large doses of chloral and bromide per rectum.

Advances in Special Therapeutics.—A series of papers was presented under this heading.

Opthalmology.—Dr. D. B. St. John Roosa discussed this subject. He said that the more modern substitutes for cocaine had not shown any superiority over that drug. Protargol, in 20-per-cent solution, had proved valuable in purulent conjunctivitis. The mechanical and surgical treatment of trachoma still maintained its supremacy. An operation still under trial was resection of the cervical sympathetic ganglia for glaucoma.

Gynecology.—Dr. Matthew D. Mann of Buffalo read this paper. He spoke of the decline of intraspinal cocainization and the growing popularity of anæsthesia by the combined use of nitrous oxide gas and ether; Thyroid extract had been found useful in certain fibroid tumors of the uterus; mammary extract was still on trial, adrenalin was useful in a few cases, while ovarian extract appeared to be wholly unreliable. Transplantation of the ovary had been shown to be possible, and that pregnancy occurred in a few instances. Present opinion was strongly against the vaginal removal of the uterus in cases of carcinoma except in very early and circumscribed growths. There had been no material improvement in the technique of operations upon uterine fibroids. Increasing experience showed that these tumors were not so innocuous as was formerly supposed.

Surgery.—Dr. William H. Carmalt of New Haven presented this topic. While fully appreciating the many disadvantages of local anæsthesia the speaker pointed out the usefulness of this method in a certain class of cases. He recommended the infiltration method with the prior injection of morphine and atropine. The occurrence of eight deaths in two thousand cases of intraspinal cocainization had made all conservative surgeons disinclined to practice this method farther. The use of Coley's toxins in inoperable cases of sarcoma was justified by the statistics, and it should be remembered that even where they failed to cure they often markedly inhibited the growth. Tetanus antitoxin was thought to be worthy of trial, considering the formidable nature of this affection. Reference was also made to operation in cases of hepatic cirrhosis and to the operation of decortication of the kidney for chronic Bright's disease.

Obstetrics.—Dr. Charles Jewett of Brooklyn considered in this paper only the subject of eclampsia. He thought that American obstetricians would do well to make more extensive trial of moderate doses of morphine in puerperal eclampsia. Post-mammary injection of saline solution, with or without the addition of sodium acetate for its diuretic action, was a useful adjunct. With regard to Cæsarian section for placenta prævia, the author showed by statistics that there was little to recommend this operation, and that, while it might be justified in exceptional cases, it was not to be looked upon as an ideal method of treatment.

Laryngology.—Dr. Charles H. Knight of New York read this paper. He referred first to the recent practice of obliterating nasal deformity by injections of paraffin. The use of adrenalin and cocaine in nasal surgery, he thought, possessed advantages which far outweighed the disadvantages. The proof that chloroform was especially dangerous in children having adenoids was overwhelming; nevertheless, he was in favor of using some other anæsthetic in adenoid operations. The operation of curetting in laryngeal tuberculosis should be reserved for superficial or circumscribed laryngeal disease occurring without an active tuberculous process in the lungs. The most satisfactory sedative for these cases was orthoform, conveniently administered in the form of a lozenge.

Orthopedics.—Dr. Newton M. Shaffer gave a brief sketch of the establishment of this specialty, and outlined what he hoped and believed would be its future.

Genitourinary Surgery.—Dr. Eugene Fuller presented, under this heading, a report of a case of hæmophilia with severe hæmaturia. The child was a Hebrew, and three or four of its brothers had died of hemorrhage following ritual circumcision. The usual treatment for the hæmaturia in this boy having had no effect, and the child being so weak from loss of blood that he could not raise himself in bed, he was put upon thyroid extract, five grains, three times a day. Improvement was noted almost from the very first, and he returned to the clinic two weeks later practically well. The speaker also dwelt upon the modern treatment of gonorrhœa, the value of antiseptics, and the great disadvantage, not to say danger, of using anodynes either before or after genitourinary operations.

Electrotherapeutics.—Dr. William James Morton read this paper. He said that the greatest recent advance in this department of therapeutics was in the use of high frequency, high potential currents. If the dermatologists would only give a fair trial to the brush discharge, he felt sure they would be pleased with the therapeutic result. Recent observations had shown that the actinic rays from an arc light may pass through the human body and may then be capable of acting upon a photographic plate beyond.

Pediatrics.—Dr. Charles G. Kerley said that one of the great advances of recent years in pediatrics was the securing of a pure milk supply and the scientific modification of that milk so as to best adapt it to the individual child. Another important step in advance was in the treatment of infantile summer diarrhœa. Much progress had also been made in the knowledge of the limitations of drug treatment, and in a better appreciation of the essential features of child life.

Dermatology.—Dr. Charles W. Allen read this paper. He said that he made use of Lugol's solution as a test stain in obscure cases of tinea versicolor, pityriasis rosea and similar cutaneous affections. In the dermatomycoses formalin solutions had proved very useful. For intertrigo a solution of methylene blue was both efficacious and agreeable; the only drawback was its color. Radiotherapy was, probably, the most important recent introduction into dermatology.

Neurology.—Dr. Edward D. Fisher presented this report. He said that his experience with trional, sulphonal, and dormio was that they did not produce sleep in painful conditions unless aided by opium, and that the system soon became accustomed to the dose, necessitating its increase. The slower action of sulphonal was often useful in prolonging the effect of a small dose of trional. He had found antipyrin with the bromides very useful in the treatment of mild forms of epilepsy and also of insomnia. In his hands, aspirin had proved beneficial in doses of ten or fifteen grains for the relief of neuralgia. A combination of pyramidon with the salicylates was valuable in the treatment of neuralgia. Cannabis indica, combined with digitalis, was a combination of much value, when used continuously for a long time, in the treatment of neurasthenics suffering much from depression and cardiac palpitation.

THIRD DAY—THURSDAY, MAY 15.

The Therapeutic Use of the Organic Extracts.—Dr. Oliver T. Osborne of New Haven presented this paper. Speaking of the thyroid gland, he said that the function of this gland seemed to be to regulate the peripheral circulation and the secretion of the mucin. He believed that the dose of all these glandular extracts should be small, as the physiological output from the glands was small. In simple goiter he could see no advantages in thyroid extract treatment *per se*. As he believed Graves' disease was due to a hypersecretion of the thyroid, the extract of this gland seemed to be contraindicated as a remedy in the active stage of this disease. If there were cerebral excitement, palpitation and progressive loss of weight, thyroid treatment was contraindicated, but if the patient were apathetic, had no palpitation, and was increasing in weight, thyroid extract was probably beneficial. He believed many cases of so-called hysteria were caused by temporary disturbances of the thyroid gland. He believed it was dangerous to use large, or even moderate, doses of thyroid extract for the purpose of reducing the body weight, particularly in persons showing a family tendency to obesity. The increase of weight occurring after the age of forty years was due, in his opinion, to the atrophy of the thyroid gland, which takes place at this time. The feeding of thyroid produces a tendency to hemorrhages; hence this remedy was of value in amenorrhea. When the physiological reduction of the thyroid secretion was not gradual about the time of the climacteric, the flushings and other nervous disturbances characteristic of this period were apt to be troublesome. In the insanities developing at this time of life it might be well to try thyroid extract. He had not found in the literature the report of a single well-authenticated case of acromegaly in which an autopsy disease of the pituitary body had not been found. It had been recently asserted that in acromegaly there was a retention of the tissue-building substances, and the similarity of the changes occurring in the osseous system in this disease to those observed in phosphorous poisoning would seem to point to the presence in the body in the early stages of an excess of phosphorous. He had found no remedy which would relieve the excruciating headache of acromegaly so well as tablets of pituitary extract. He was convinced that thymus treatment was often of service in cases of hypersecretion of the thyroid. For several years past he had given thymus to all of his tuberculous patients, and had found that the patients uniformly did better when given this extract in addition to the usual methods of treatment. From six to nine grains should be given three times a day. No case of sudden cardiac failure or shock should be allowed to terminate fatally without at least a trial of adrenalin. Of the 1 to 1,000 solution from five to ten drops should be given every fifteen minutes for a few doses, and then once in three hours. Adrenalin solution should be used in Addison's disease, anæmia and other conditions characterized by low blood pressure. In shock from anæsthesia and narcotic poisons, especially morphine, there was an indication for the use of adrenalin. The therapeutic value of ovarian extract was still in doubt. The benefit derived from the administration of testicular extract appeared to be wholly due to the nucleoalbumin contained in this extract. He had tried parotid gland in dysmenorrhea with apparent benefit.

Dr. George E. Tyler of Denver, Colo., said that in a number of cases in which marked nervous phenomena had followed the artificial menopause, he had apparently secured good results from the administration of the ovarian extract.

Dr. Carl Beck of New York said that his skepticism regarding organotherapy had received a rude shock by witnessing a case in which uterine myoma had been greatly reduced in size by the administration of mammary extract.

The Treatment of Opium Addiction.—Dr. Smith Ely Jelliffe of New York read this paper. There were three great classes of opium takers, he said, viz.: (1) Those making use of the ordinary pharmacopœal preparations of the drug; (2) Those taking it by smoking or smelling, and (3) Those taking morphine or its preparations by the mouth or subcutaneously. Great stress was laid upon the temperamental variations observed in this drug habit. The treatment recommended by the author had for its basis: (1) The substitution of different sensations by the use of other drugs, and (2) The substitution of different ideas by suggestion. Hyoscine hydrobromate, in doses sufficient to produce a stuporous condition had proved useful in his hands. Under the use of heroin and dionin there was a cessation of the craving and a sense of contentment was established.

Rontgen Therapy in Carcinoma.—Dr. Carl Beck of New York presented this paper. He said that soft tubes should be used for carcinoma of the skin and hard tubes for the deeper growths. The exposures for the first week should be only five minutes each, but, if there were no undue reaction, the exposure could then be increased to ten minutes and the interval gradually diminished. At first the tube should be placed two inches from the part. A noteworthy feature of the treatment was the speedy disappearance of the pain. Three patients were presented.

Dr. Robert Reyburn of Washington, D. C., expressed the belief that the principle of treating cancer by the knife was radically wrong, because of the exposure of the lymphatic channels to fresh infection with cancer. Caustics were improvement on the knife; the Röntgen ray was still better.

Dr. George E. Tyler hoped the enthusiasm over this Röntgen therapy would not lead to procrastination in the use of the knife.

Dr. Beck indorsed the views of the last speaker both on theoretical and clinical grounds.

The Treatment of Gonorrhœal Arthritis.—Dr. De

ROBERT WILLARD of Philadelphia was the author of that paper. He said that as soon as [illegible] had [illegible] the joint should be tapped and the [illegible] withdrawn and examined for gonococci. The diagnosis having been made, free incisions should be made on both sides of the joint and posteriorly, and the joint cavity cleansed out most thoroughly with some bactericidal fluid. After this washing, if suppuration had not already occurred, drainage was not necessary, and the dressings and splint should be left undisturbed for ten days. Then massage, dry superheated air and passive motion should be employed to restore the function of the joint. If the joint refilled, the process should be repeated with or without drainage. The operation should be performed before any serious symptoms had arisen, and of course the source of the infection should be carefully treated to prevent a new infection. In the neglected cases a skiagraph should be taken, and then, on several successive occasions, under ether, an effort should be made to break up the adhesions.

Officers Elected.—*President*, Dr Thomas E. Satterthwaite of New York; *Vice-Presidents*, Drs. Howard H. Baker of Washington, D. C., J. N. Hall of Denver, and Oliver T. Osborne of New Haven; *Secretary*, Dr Noble P. Barnes of Washington, D. C.; *Recorder*, Dr William M. Sprigg of Washington, D. C.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, Held May 1, 1902.

ROBERT F. WEIR, M.D., PRESIDENT.

Abscess of the Prostate.—Dr SAMUEL ALEXANDER presented a paper on this subject. He said that periprostatic abscess was an extension of a prostatic infection, a later development of prostatic abscess. Prostatic abscess, though of frequent occurrence, often passed unrecognized until it had destroyed certain adjacent structures. In nearly all cases such abscesses were the result of an infection derived from the urethra through the excretory ducts of the gland, the determining cause usually being traumatism. The amount of trauma necessary to produce suppuration of the prostate varied with the resistance of the organism. Sometimes such a slight trauma as an ordinary urethral injection was sufficient. Theoretically, infection through a single duct should infect only the one lobule, but in the urethral mucous membrane the infection of more than one lobule was the rule rather than the exception. Immediately preceding the formation of prostatic abscess the gland becomes swollen. One cause of the swelling was obstruction of the excretory ducts, another cause was the œdema resulting from the flow of blood through the prostatic plexus of veins becoming impeded. This swelling may be increased by sexual excitement or by increased frequency of urination, especially if the latter is associated with straining. The proof of this was to be found in the fact that when a catheter was used to drain the bladder, thus eliminating the straining efforts, the œdema of the prostate rapidly subsides. Abscess of the prostate terminates in several ways, viz. the pus may be discharged outside of the capsule into the perineum, or ischiorectal fossa, or open into the urethra. Such openings always occur on the floor or the side of the urethral canal below the upper margin of the veru montanum. In prostatic abscess the pus escapes just below and to the outer side of the apex of the prostate, in the case of the perineum, and just to the side of the apex of the prostate, in the case of ischiorectal abscess.

Diagnosis.—In cases of prostatic abscess there was almost always a very large quantity of albumin found in the urine, entirely out of proportion to the pus or blood present, or the existing renal disease, and which disappears promptly on opening the abscess. The probable explanation was that as a result of the pressure upon the veins and the arterial current was [illegible] out into the posterior urethra and into the urine. Careful bimanual palpation would also detect an abscess of the prostate.

Operation.—When the abscess had extended outside of the capsule, operation was always indicated. The opening of the abscess through an incision made in the anterior wall of the rectum could not be too strongly condemned; these abscesses should be operated upon through the perineum and before periprostatic suppuration had occurred. The operation advocated was the opening of the prostatic abscess into the urethra by the ordinary perineal section. It should be remembered that the nearest approach of these abscesses was on the floor and the sides of the urethra above the veru montanum. The membranous urethra should be divided on a broad staff, and the prostatic urethra dilated with the finger. With another finger in the rectum, the point of greatest fluctuation is discovered, broken through and the bladder then drained for three or four days. In a great many cases epididymitis occurs, and nearly always the patient is up in five or six days, and at the end of the second week he is able to pass all of the urine through the urethra.

Dr BRANSFORD LEWIS of St. Louis presented a number of plates, specimens and models illustrating prostatic hypertrophy.

Dr JAMES BELL of Montreal reported an illustrative case beginning as a prostatic abscess, subsequently becoming periprostatic, and opening first anteriorly, then laterally and finally into the rectum, thus emphasizing the points brought out in the paper.

Dr PAUL THORNDIKE of Boston said that the text books spoke of abscess of the prostate as a very common and dangerous disease. All would admit that it was common, but whether or not it was dangerous was a matter of opinion. He had only once seen a dangerous case, but he had been deeply impressed with the amount of pain and misery associated with this condition. When frequency of micturition was followed by pain and swelling, and the condition could not be quickly relieved, the time had come for operation. The dissection down upon the prostate between the urethra and the rectum was attractive to all, nevertheless, it left a large, deep wound which was slow to heal. Dr Alexander had suggested as a method of operating one which was similar to his operation for the enucleation of the prostate, and it was technically easy and rapid, while convalescence after it was smooth and prompt. Occasionally the cases of œdema or congestion could be easily palliated, and for this purpose the tying in of a catheter would be found exceedingly useful.

Dr F. TILDEN BROWN said he could substantiate what the author had said about the urine being markedly albuminous in these cases, and was inclined to accept the explanation given. Occasionally one met with a periurethral folliculitis, independently of an original prostatitis. In these cases the introduction of the finger into the bowel was extremely painful, as compared with what it was in cases of prostatic abscess. He suggested that after opening the prostatic abscess by the method described by Dr Alexander, it might be better to make a counteropening through the apex of the capsule of the gland, and using a light gauze dressing instead of a rubber drainage tube.

Dr GEORGE E. BREWER said that he had frequently seen cases in which there was practically no fever, and cases in which even the retention disappeared or the irritability of the bladder became less, despite the presence of pus in the prostate gland. It was well to remember in obscure cases that the existence of suppuration was usually indicated by a leucocytosis. The older method of operating upon prostatic abscess had served him so well that he was not prepared to unreservedly indorse Dr Alexander's method of opening abscesses into the anterior urethra. It seemed to him much better to evacuate the abscess into the perineum without rupture into the bladder or urethra. In operating it should not be forgotten that sometimes these abscesses are multiple.

Dr. B. Farquhar Curtis said he had been surprised to hear the statement that prostatic abscess is a common disease, certainly it was not in the experience of the general surgeon. In tuberculosis of the prostate the capsule becomes distended, and owing to the painlessness of the condition the surgeon could readily study the distribution of the capsule. For the old periprostatic cases the horseshoe incision anterior to the sphincter seemed to him the best means of draining the ischiorectal spaces on either side of the prostate. In earlier cases, in which there was no infection from without, Dr. Alexander's method of operating seemed a valuable one. The dissection between the rectum and bladder seemed to him to be a comparatively simple one, the only disadvantage being the possibility of the formation of a sinus, yet he had healed these cases, even when tuberculous, without a permanent sinus. He was one of those who favored the method of draining the bladder by tying in a catheter.

Dr. John Vander Poel spoke of the obscurity of the etiology of prostatic abscess. He thought a distinction should be made between so-called follicular abscesses and true abscess of the prostate. The former might be present for a long time without giving rise to pronounced symptoms. Catarrhal prostatitis or prostatic congestion was exceedingly common, resulting from (1) Venereal excitement; (2) Such excitement without gratification; (3) Masturbation, and (4) By withdrawal. Such congestion favored bacterial infection.

NEW YORK ACADEMY OF MEDICINE.

SECTION ON OBSTETRICS AND GYNECOLOGY.

Stated Meeting, Held April 24, 1902.

James N. West, M.D., Chairman.

A Large Vaginal Cyst Removed in Toto.—Dr. H. J. Boldt presented this specimen. Beginning on the anterior wall of the vagina, he had traced it up into the broad ligament, and had slowly dissected it out. There was a good deal of hemorrhage, as was usual in cases of vaginal cyst. It was his opinion that the large cysts originate from the parovarium or the Wolffian ducts, while the small ones arise from a gland in the vaginal wall. He thought it a better procedure to extirpate the summit of the cyst, and unite the sac and vaginal mucous membrane.

Ruptured Tubal Gestation; Formation of Hæmatocele with Rupture of the Hæmatocele Wall.—Dr. Boldt reported this case, and presented the specimen. The patient was a woman of thirty, the mother of one child, born seven years previously. There was the usual history of ectopic gestation, except that she had not missed a menstrual period. However, with the onset of this period, an atypical bleeding and characteristic cramp-like pains had become the prominent symptoms. When the bleeding was not free the pain became excruciating. These symptoms had existed for five weeks before he saw her. Examination revealed a retrouterine mass with an indistinct outline toward the median line. On the right side was what appeared to be a hæmatocele. On the following day, on performing abdominal section, a rent was found on the inner side of the hæmatocele, through which clots and fluid blood were escaping into the peritoneal cavity. Convalescence progressed favorably.

Extirpation of the Uterus and Vagina for Complete Procidentia.—Dr. Boldt said that this patient was an aged widow, who had been prevented from attending to her household duties by the prolapse. The operation, described by Edebohls, seemed to him appropriate for this case, as the technique was simple and a permanent cure seemed to be assured. Seven sutures were used to columnize the vagina. The patient was doing well. The speaker said that when the vagina was not to be obliterated the most satisfactory results had been obtained by an anterior and posterior colporrhaphy with a perineorrhaphy. The abdomen was then to be opened and a high ventral fixation done.

Dr. Bache Emmet thought there would seldom be any need for this operation, as the same result could be practically secured by closing the vagina.

Benign Tumors Complicating Pregnancy.—Dr. Bache Emmet presented this paper. (See page 805.)

Malignancy Complicating the Pregnant State.—Dr. Simon Marx read this paper. (On page 808.)

Uterine Displacements Complicating Pregnancy.—Dr. Edward A. Ayres was the author of this paper. He said that such displacements, by their interference with the circulation in the uterus, were prone to cause abortion. Marked hypertrophy of the cervix was sometimes mistaken for procidentia. In order to prevent abortion, the patient should remain in a recumbent posture as much as possible, the uterus should be supported by inflated soft rubber rings, and as much room as possible above should be obtained by regular and thorough evacuation of the bowel and the use of a light diet. Pernicious vomiting might result from incarceration of the uterus in the pelvis. Efforts to replace the organ by taxis should be made after emptying the bladder by catheter. Unusual difficulty in micturition should awaken suspicion and lead to investigation. The bladder was certainly drawn upward to an enormous extent by the presence of adhesions, but such cases were best let alone, as the gradual enlargement upward of the uterus was the best taxis. The operation of ventral fixation was now generally considered to be a probable source of trouble in pregnancy, while the operation of suspensio uteri, or the union of the uterus to the abdominal wall by a band of peritoneum of indefinite length, rarely give rise to obstetric complications. Operations which shorten or double up the ligaments of the uterus were vicious from the standpoint of the obstetrician. Ovarian cysts often demand operation, and it was well to remember that, when operative interference was required, it could be done during the fourth month of pregnancy with the least risk of interfering with the progress of pregnancy. When the removal of the complicating tumor would probably prove a difficult or serious procedure, it was better to empty the uterus and postpone operation until after the mother had recovered from this. The hernias of the pregnant uterus were umbilical, ventral and inguinal. Pregnancy and labor might be seriously interfered with by certain forms of intestinal hernia. Inguinal and fermoral herniæ discovered during pregnancy should be reduced, if possible, and suitable trusses applied. Vaginal hernia should be reduced, or, if this were not possible, should be kept empty by ballooning the vagina with a colpeurynter until the latter was pushed out.

Inflammatory Diseases Complicating Pregnancy.—Dr. Henry C. Coe discussed this topic. He said that acute gonorrheal infection of the pregnant uterus was fortunately infrequent, although the chronic form was common and, in his opinion, was the cause of premature delivery more often than was generally recognized. The treatment of acute endometritis in pregnancy followed the ordinary rules. The best treatment of chronic endometritis was thorough curettage and cauterization of the uterus. As the preparation for a subsequent pregnancy, this treatment often proved most successful in women who had repeatedly miscarried. That acute oophoritis might complicate pregnancy he had shown in a paper published in 1892. Where the abscess could be clearly located, the line of treatment was clear. A median section after the sixth month of pregnancy would be attended with serious risk of infection. With pus clearly pointing in the posterior or vaginal fornix, the patient's chances would be improved by incising at this point rather than trusting to spontaneous rupture. He had known a cystic ovary to become a true ovarian cyst in the course of pregnancy. He would not hesitate to open the abdomen to break up periuterine adhesions if the pathogenic [illegible]. In cases of old gonorrheal pyosalpinx the culture was often sterile. The probability of fresh infection from the side of the bowel where the diseased organ was adherent to the intestine, should be borne in mind, and due attention given to the state of the bowels. In cases of pregnancy requiring laparotomy for any reason, be careful about making the incision to the right of the outer border of the rectus. Possible abscess and fissures of the rectum and hemorrhoids often caused serious inconvenience to the pregnant woman.

What Aid Can the Pathologist Give in Diagnosis and Prognosis in Complications of Pregnancy.—Dr. WILLIAM S. STONE read the paper. He said that a complete history would greatly help the pathologist in his effort to aid the clinician. He had known chancroid of the cervix to be confused with malignant disease and only differentiated by microscopical examination. The possibility of the presence of deciduoma malignum in every case of irregular bleeding, particularly after the discharge of a uterine mole, should be borne in mind. The examination of the vaginal discharges during pregnancy might be the means of preventing infection in the puerperium. Examinations of the blood in cases of severe infection often afforded an index of their severity.

Discussion on the foregoing papers was postponed to the next meeting, owing to the lateness of the hour.

Surgical Suggestions.

Inguinal Adenitis.—If healing progresses slowly, the granulations may often be stimulated by ichthyol combined with blue ointment. If the case progresses as it ought, evidences of outstanding inflammation should disappear, as well as lymphatic hypertrophies, and the cavity should gradually fill up with solid granulations.—EUGENE FULLER.

Ecthyma.—To cause the crusts to fall and regulate the local circulation:

℞	Safran	0.40	gm.
	Sulphate of zinc	7	"
	Sulphate of copper	2	"
	Boiled water, camphorated, to saturation and filtered	1	liter.

—SABOURAUD.

Manson's Method is by far the safest method in the case of abscesses buried deeply in the substance of the liver. The tapping is done by a trocar and canula, and a large tube inserted stretched on a metal rod through the canula to the bottom of the cavity. Thereafter siphon drainage is employed, and the cavity is left to drain without either washing out or flushing. The chief danger lies in the possibility of displacement of the tube.—*Cantlie*.

Anthrax.—Sclavo's serum has a specific action. Carbolic acid may be used until the serum becomes accessible. Incisions may be made at a distance from the local process.—FERRIER.

Various Hints.—In fracture of the patella, whether treated by wiring or any other method, the limb should be immobilized for about six weeks.

In operating for appendicitis, if you find coils of intestine adhering to each other, always wall off the rest of the peritoneal cavity with sterile pads as if you knew that you were dealing with an abscess, for you can never know how soon a sudden gush of pus may take place.

After intra-abdominal operations distress from gas low down in the bowel is best relieved by enemata of hot water. If there is some shock and the presence of intense thirst, or if the latter alone exists, a pint of saline solution by the rectum will relieve the shock and to a considerable degree assuage the thirst.

In bullet wounds of the stomach if there is a posterior opening which cannot be reached by incising the anterior layer of the great omentum midway between the colon and the greater curvature of the stomach, it will be necessary to open the anterior wall, repair the posterior wall through the opening, and then close the anterior one.

In intestinal paralysis following operative procedures within the abdominal cavity give a high enema consisting of sulphate of soda, sulphate of magnesia, inspissated oxgall, 2 drachms each, and turpentine 1 drachm, in a pint of warm water. The prompt use of this injection has saved many lives.

In operating beware of too many assistants. They will surely get in each other's way unless trained to a high degree of efficiency. It is also well not to have too many instruments. Provide those that are needed and those which an emergency may call for, but have nothing that is unnecessary and not too many instruments in the pan.

In operations for chronic conditions of all kinds in adults it is well to estimate beforehand the amount of urea that is being excreted by the patient. If, as is very often the case, the excretion of urea is diminished, it is wise to institute some preliminary treatment for the condition. Attention to this point will bring about more satisfactory results.

In old prostatic cases rapidly increasing difficulty in urination is often caused by constipation. If the bowels are thoroughly moved the difficulty will often disappear in great part.—*International Journal of Surgery*, December, 1901.

More Hints.—In cold weather, when making use of chloride of ethyl for local anæsthesia, it is well to warm the part beforehand. This will secure better evaporation and more complete anæsthesia. It also prevents waste, as a much smaller amount of the chloride of ethyl will produce the required degree of anæsthesia.

Never use sutures larger than are necessary to properly maintain approximation, or ligatures larger than will suffice to hold safely the vessels or pedicles they are to constrict. Even when absorbable they are foreign bodies.

If there is no evidence that a bullet has perforated important organs, such as the hollow viscera, or that it is causing hemorrhage, or that it is producing dangerous pressure, no attempt at extraction should be made. The wound is to be treated antiseptically. If sepsis should occur, the general rules governing the treatment of septic foci must be applied.

In a wound occurring in some place where no aseptic dressings can be procured, it is better to leave it exposed to the external air than to cover it with probably infected substances. A protective crust or scab will thus rapidly be formed.

Whenever tendons are sutured it is necessary to maintain the limb in such a position that the muscles whose tendons have been rejoined shall be as perfectly relaxed as possible. In suturing nerves the parts should be kept absolutely at rest for a period of at least three weeks.

A surgeon who keeps on breaking small ligatures when tying minor bloodvessels gives evidence of the fact that he is using an altogether unnecessary amount of force, at least ninety-nine times out of one hundred.

Any dressing or apparatus applied to a person either insane or suffering from delirium tremens must be proof against the almost certain efforts on the part of the patients to tear these away.

In the case of a wound of the skull in which there is evidence of depression, even to the slightest extent, and if the means of doing aseptic surgery are at hand, conservative surgery is out of place. It is now a cardinal rule that depressed bone in the skull must be elevated or removed.

In erysipelas of the face of uncertain origin always examine the nasal cavity. The starting-point of the infection is sometimes to be found in small purulent collections confined beneath crusts, or in pustules situated around the hairs at the meatus.—*International Journal of Surgery*, 1902.

Medical Items.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, New York City, for the week ending May 17, 1902:

	Cases.	Deaths.
Measles	450	20
Diphtheria and croup	281	44
Scarlet fever	402	41
Smallpox	58	9
Varicella	68	..
Tuberculosis	294	168
Typhoid fever	23	14
Cerebro-spinal meningitis	..	3

Precautions Against Cholera in Manila.—The following sanitary order was issued by the military authorities in the Philippines, on the appearance of cholera in Manila:

1. Asiatic cholera is a disease the infection of which is taken in by the mouth. As a preventive it is therefore necessary to eat or drink only articles in which the infective principle has been destroyed by distilling, cooking, etc. Unboiled water, including aerated waters not imported, and sorbete, the native ice cream, fresh vegetables of any sort, as lettuce, cabbage, fresh fruits, etc., which are not cooked in their preparation are, therefore, dangerous and to be avoided. In addition, the greatest care must be given to the preparation of foods and the dishes on which they are prepared or served. The infection may be carried by washing such dishes with infected water or by wiping them with cloths which have been washed in such water.

2. All officers stationed in the division of the Philippines will give personal instructions and care to see that no member of their family, or servant of their household, drinks water that has not been distilled, or if not distilled, that has not been thoroughly boiled for at least twenty minutes, or any aerated waters that have not been imported, or sorbete, or eat fresh vegetables or fruit of any sort which have not been thoroughly cooked. Further personal care and superintendence is enjoined in the use of boiled water in the washing of dishes and the boiling of clothes, which have been used to wipe such dishes. The irresponsibility and ignorance of native cooks render careful supervision of the kitchen imperative, in order to avoid this disease.

3. The same care is enjoined, as specified in the preceding paragraph, in the use of water and preparation of foods in barracks or other buildings or camps where enlisted men or government civilian employees are stationed. All soldiers and all United States civilian employees are forbidden to use water for drinking obtained from the rivers or wells in the vicinity of Manila, unless the same has been distilled or thoroughly boiled. No excuse for ignorance in regard to this will be accepted, and proper disciplinary measures will be applied for any violation of this paragraph.

4. In order to prevent possible infection of food by flies, company commanders and other persons in the military service or attached thereto, in charge of messes, are enjoined to take the necessary measures to protect all food from flies and other insects. That this may be carried out, food should not be placed upon the table until immediately before it is to be served, and it should be covered at all times. The attention of company commanders and other persons in the military service, or attached thereto, is called to the necessity of care in covering the contents of dry earth or other closets with earth or chloride of lime, in order that flies may not have access to such contents, with possible transference of infectious material by such flies to foodstuffs.

5. As the division commander cannot be certain that saloon-keepers will not serve unsterilized water for customers to drink, all persons in the military service or civilian employees therewith are directed to confine their drinks at saloons, if they drink at all, to beer.

6. A sentinel or responsible watchman will be posted at every faucet where water is obtained from city water mains for army use, and such sentinel or watchman will be instructed to let no person drink thereat.

7. All officers and employees of the transport service, ships chartered or otherwise employed in the military service, will be at once warned to comply strictly with the foregoing regarding consumption of vegetables, etc., and drinking water.

8. All persons affected with diarrhœa or vomiting will report themselves immediately to their medical officers for treatment.

9. All cases of cholera, or cases suspicious of that disease, coming to the notice of medical officers will be immediately reported by telegraph to the chief surgeon of the division.

10. Cholera having made its appearance in Manila, careful attention to diet and the use of water rendered safe by boiling, with the avoidance of unsanitary localities, are all necessary in order to secure immunity from that disease.

11. This order will be read to all troops as soon as received and a copy kept posted in all barracks, quarters, and camps.

College of Physicians of Philadelphia.—Section on General Medicine.—At a stated meeting, held May 12, Dr. A. Hand, Jr., read a paper entitled "The Acarus Farinæ, an Occasional Parasite Found in Urine; Exhibition of Specimen." He pointed out that animal parasites may gain entrance into the urine (1) through the blood, (2) from the surface of the body or the clothing, (3) by contamination subsequent to voidance. He reported three cases in which the acarus farinæ was found—in two cases in children and in one in the father of one of these. The channel through which the parasite gained entrance was not clear, although it may have been through the intermediation of a dusting powder. Drs. J. D. Steele and A. P. Francine reported a case of cancer of the stomach in which the tumor was demonstrable by palpation and percussion and its detachment from the colon was shown by inflation of the colon. Drs. Charles W. Burr and A. C. Buckley reported a case of spinal rigidity due to rheumatoid arthritis, with autopsy. The patient was a young man who presented, in addition to rigidity of the spinal column and some interference with mobility at the hip and shoulder joints, cutaneous hyperesthesia, with small areas of anæsthesia on the thighs, exaggerated knee-jerks and increased plantar reflexes. Death resulted from pulmonary tuberculosis, with invasion of other organs, and post-mortem examination disclosed, in addition to ankylosis at the articulations of the lateral processes of a number of the thoracic vertebræ, slight degenerative changes in the posterior nerve-roots of the spinal cord and slight interstitial inflammation of the sciatic nerves. Drs. D. J. McCarthy and T. D. Henderson read a paper on "Spondylose Rhizomelique and the Relative Frequency of Spinal Involvement in Rheumatoid Arthritis." He related one case in which only the vertebral articulations appeared to be involved in the morbid process, with symptoms referable to the nerve-roots, and a second case in which other joints were examined. In a series of cases of [illegible] it was found that almost all of any standing exhibited some rigidity of the spinal column. Dr. J. A. [illegible] exhibited the heart from a case of aortic regurgitation with murmur audible at a distance from the chest. The phenomenon was attributed to a fenestrated aortic valve that was found.

Harvard University has awarded the Boylston Prize for 1902 to Doctor Robert L. Randolph, Associate Professor of Ophthalmology and Otology in the Johns Hopkins University. Dr. Randolph's work is an experimental one and is entitled "The Rôle of the Toxins in Inflammations of the Eye."

Health Reports. The following cases of smallpox, yellow fever, cholera, and plague have been reported to the Surgeon-General, U. S. Marine Hospital Service, during the week ended May 17, 1902:

SMALLPOX—UNITED STATES.

THE TREATMENT OF CHOLELITHIASIS.*

WITH REPORTS OF ILLUSTRATIVE CASES, INCLUDING ONE OF CHOLELITHIASIS IN A CHILD ELEVEN YEARS OLD.

By HOWARD LILIENTHAL, M.D.,
ATTENDING SURGEON TO MT. SINAI HOSPITAL,
NEW YORK.

IN the treatment of disease it is the aim of the good physician to weigh carefully the peril or distress in which the patient is put by the malady and the possible dangers of the means which may be selected for his relief. A dangerous disease often demands a remedy which in itself may put life in jeopardy; but the risk is justified by the restoration of the health of the individual, who, without this risk, would have had to face early dissolution or an invalidism with the ever-present danger of fatal complications. Certain disorders will at once be brought to mind as belonging to this class, in which danger must be fought with danger, and eminent among these are the various infections of important or vital organs associated with conditions which may be relieved by mechanical means alone. Calculous disease at once occurs to us as the most perfect example of this class of ailments; yet, while urinary stone has, since ancient times, been regarded as a condition demanding surgical treatment, it has remained for the surgeons of our own time to point out the therapy of concretions within the vermiform appendix and those of the biliary passages. To be sure, an American surgeon, Dr. John Stough Bobbs of Indiana, did perform the first recorded operation for cholelithiasis, which he called "lithotomy of the gall-bladder," June 15, 1867,[1] with perfect success, but his example was not followed for many years.

Biliary calculi, according to Naunyn and Frerichs, quoted by Shattuck,[2] are due to the precipitation of cholesterin around a nucleus of precipitated bilirubin calcium, the process being caused by changes in the bile from stasis and catarrh. The presence of clumps of certain bacteria may also have an influence on the formation of the nucleus of a gallstone, and, indeed, M. W. Richardson of Boston has caused calculi to form in the gall-bladders of rabbits by injecting typhoid bacilli directly into the viscus.

The formation of gallstones may, to a certain extent, be prevented by exercise and the promotion of regularity of intestinal action. Stones having formed in the gall-bladder, however, it is impossible, so far as our present knowledge goes, to dissolve them or remove them by medical means alone.† (Kocher,[3].)

The next point to be considered, then, is, What may be the consequences of the presence of gallstones?

1. They may lie quiescent or latent within the gall-bladder, and in this case may do little, if any, harm.
2. Quiescent stones may, by constant slight irritation, cause carcinomatous degeneration of the gall-bladder or its passages. (Cumston,[4]; Kehr,[5].)
3. Gallstones may give rise to attacks of pain of the greatest severity. So terrible may this pain be that it has of itself caused death (Thomson,[6]), and the attacks may become so frequent as to make life practically unendurable.
4. Jaundice, with all its discomforts and dangers, is a common accompaniment of the stoppage of the common duct by stones or by the swelling of the mucous membrane caused by their presence.
5. Ulceration and infection of the gall-bladder.
6. Great tension of the gall-bladder, often with empyema of that organ, due to impaction of a calculus in the cystic duct.
7. Gangrene and perforation of the gall-bladder, with all the dangers which these accidents imply.
8. Cholangitis, extending into the finer ramifications of the biliary passages; a condition almost uniformly fatal.
9. Intestinal obstruction from adhesions around the gall-bladder, or from the presence within the gut of a gallstone of such size as to cause obturation.
10. Cirrhosis of the liver with all its disastrous consequences (Kehr,[7]), from prolonged obstruction of the common duct.

There are other evil results from the presence of tone besides those mentioned, but the list as it stands will suffice to show that cholelithiasis is not a condition to be taken lightly, either by the unfortunate patient or by his physician.

Knowledge of the existence of latent cholelithiasis should put us on our guard against the various complications and sequelæ which may occur. Medicine can do much toward preserving the latency of the disease and averting attacks of colic. Just as soon, however, as there appears a tendency to frequent or severe attacks, or whenever a complication arises, such as the impaction of a calculus or an acute infection of the gall-bladder, or when there is a steady boring pain in the epigastrium and in the dorsal region with intermittent icterus, indicating the presence of a stone in the common duct without true impaction, the case becomes one for the surgeon, and a delay on the part of the physician may be considered fully as culpable as delay in appendicitis.

Indeed, M. H. Richardson[8] goes so far as to maintain that gallstones should be removed as soon as their presence has been diagnosticated, unless a single stone without facets has been passed by the rectum, when it may be assumed that there are probably no others in the gall-bladder. This is by no means an invariable rule, however, for I have several times found more than one unfaceted stone.

Disease of the gall-bladder is, in many respects, similar to disease of the vermiform appendix. Concretions are as little likely to be removed by nature or by internal medicine in the one case as in the other. Spontaneous permanent cures are in both instances equally improbable. Acute infections are as dangerous in the one organ as in the other, or, perhaps, rather more dangerous in the case of the gall-bladder, for here we have jaundice and cholangitis as possibilities in addition to the peritonitis common to both complaints. Malignant degeneration, too, is much more common as a result of gallstones than of appendicitis. Both diseases call for surgical intervention, although, as a rule, the operations for cholecystitis are of somewhat greater magnitude than those for the relief of appendicitis.

---

*Read before the Metropolitan Medical Society, March 25, 1902.

†The few exceptions to this rule are in the case of very small stones. When large stones appear in the stools it is more than likely that they have ulcerated into the intestine, and not passed by the natural channels.

Surgery can go very far toward effecting a radical cure in these most serious cases, and, if the patients are operated upon in time, the mortality rate is surprisingly low. In fact, it is now pretty generally understood that as in appendicitis so also here the results of the surgeon depend entirely on the skill and wisdom of the physician in recognizing the approach of danger before it has become imminent.

I have operated many times for gall-bladder disease, twelve times extirpating the entire organ. But one patient has died who might reasonably have been expected to recover, and several of the worst cases have been cured. The fatal case referred to was my first of cholecystectomy, the operation having been performed June 18, 1896, for complete organic stricture of the cystic duct. The gall-bladder was very tense and contained transparent serous fluid unstained by bile. The patient stood the operation well, and there was but little shock. The incision—a "cross cut" of the rectus, which I have now practically abandoned—was carefully closed by silk suture in five layers, but the following day, during a severe fit of coughing, the wound opened and the intestines prolapsed. Neither the ward nurse nor the house staff recognized the trouble until several hours had elapsed, when the prolapse was reduced, but the patient died of peritonitis. With this single exception, the fatal cases were all those of patients suffering from sepsis or chronic icterus.

My list of operations comprises cholecystotomy with drainage, which is the simplest of all; ideal cholecystotomy, in which the stones are removed and the gall-bladder closed by suture, cysticotomy, or incision of the cystic duct, choledochotomy, the most difficult and dangerous of these operations, the incision of the common duct, and, last and most radical, though not the most difficult, cholecystectomy, or the complete removal of the offending viscus.

The choice of the kind of operation for each individual case is of the greatest importance, and it must depend largely on the general condition of the patient, as well as upon the character of the disease. In the early days of gall-bladder surgery it was considered sufficient to relieve the tension or drain the suppurating viscus regardless of such unfortunate results as bile fistula, or continued common-duct obstruction, or frequent relapses with the necessity for repeated operative drainage of the gall-bladder. In this respect we note another parallel with appendicitis, which was formerly treated by mere drainage of the perityphlitic abscess, often repeated a number of times. Just as now we try to effect a permanent cure by the removal of the diseased appendix, so there is a strong tendency to such procedures as shall accomplish a similar result in gall-bladder disease, through the complete removal of the viscus. Perhaps there is no better way in which I can illustrate the present resources of this branch of surgery than by recounting a few of my cases with special reference to the proper selection of the type of operation or the contraindications to any form of surgical therapy.

CASE I.—A lady, sixty-six years old, very stout and with a tendency to cardiac weakness from excess of fat, was seen in a first attack of cholecystitis of a mild type, due apparently to cholelithiasis. The disease was of several days' standing, and there was a distinct tumor in the right hypochondriac region. Slight icterus. Temperature 100°. Pulse regular but compressible. This case was not considered urgent, but the patient was carefully observed and treated medically, with the speedy subsidence of the attack.

Operative procedures in a patient of this type are particularly dangerous, and if undertaken at all they should be limited to the mere incision and drainage of the gall-bladder which would have been undertaken at the first sign of general systemic indications of sepsis. It is not a case suitable for the interval operation, but rather for the prophylactic internal treatment, with the hope of bringing about continued latency, which, as Kehr has pointed out, is the next best thing to a cure. In feeble or aged individuals, then, or in those suffering from other serious organic disease, such as of the heart or kidneys, palliation and not cure is the better plan, reserving operative treatment for such emergencies as may themselves directly threaten life. Here, however, very frequent and severe biliary colic with distension of the gall-bladder, in spite of thorough medical treatment, may be considered as threatening life, and the palliative operation should be performed at some time during the attack while the viscus is tense and easily reached.

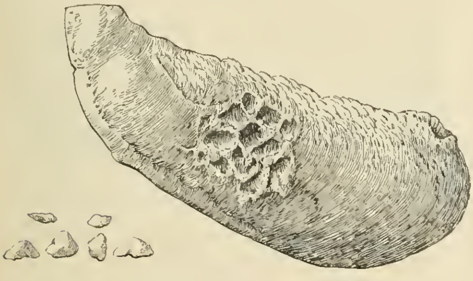
CASE II.—H. H., a gentleman, fifty years old, had frequent and severe gall colics without jaundice; otherwise he seemed healthy, and Dr. Manges, who had examined him at my request, concurring in the diagnosis of cholelithiasis, it was determined to operate. On May 25, 1901, he was admitted as a private patient to Mt. Sinai Hospital. Just before his admission he had a sudden rise of temperature to 104°, with signs of acute obstruction and infection, so there was no further delay in operating. The patient bore the anæsthetic very badly, however, there being great irregularity and shallowness of the respiration, with a wretched and flickering pulse. Immediate relief by the quickest method became imperative, so the tense gall-bladder was speedily packed into the wound and cholecystotomy performed. No stone was found in the gall-bladder and none in the cystic duct. A full and careful exploration of the other ducts was out of the question, so the wound was hastily dressed and the patient sent back to bed. Convalescence with gall fistula followed, and the man is now in excellent health, but he is obliged to wear a tube in the fistulous opening, which discharges two or three ounces of bile per day, the remaining quart or more being evidently discharged by the normal passages into the bowel.

This case would have been suitable for cholecystectomy with the removal of any calculi impacted in the ducts. This being out of the question, however, on account of the bad anæsthesia, we had to content ourselves with the next best thing.

CASE III.—Mr. L., a man thirty-one years old, was sent to me by Dr. L. Stieglitz with a diagnosis of cholelithiasis with frequent attacks of colic. The patient had had peritonitis some years before, probably from a gall-bladder infection. When I first saw him he was just recovering from an attack of colic, with slight fever and jaundice. A few days later he entered the private patient department of the hospital, and on July 23 I performed cholecystectomy. The operation was far from simple, because of numerous troublesome adhesions, apparently the result of the previous peritonitis. The thick-walled gall-bladder was of rather small size, and contained a number of irregularly-shaped pigment stones, which were so soft that they could be easily crushed between the fingers. Some of them were shaped like jack-stones, and the largest ones were the size of a large pea. After an annoying delay, due to the formation of a secondary abscess about the stump, this patient made a good recovery and remains in normal health.

This man was young and in good general health so that I was anxious to make as radical a cure as possible. Had I not removed the viscus, this could hardly have been accomplished, for the chronic infection and its resulting action upon the mucous membrane would have rendered the recurrence of cholelithiasis very probable.

Case IV.—Annie K., thirty-three years old, was admitted to my service at Mt. Sinai Hospital on January 24, 1902, with characteristic cholecystitis. There was a history of repeated attacks of epigastric pain, with vomiting, followed by jaundice. When admitted she had been sick three days, had had chills and vomiting and a temperature of 105°. The urine and stool were negative on examination. The liver was somewhat enlarged and the entire abdomen distended, with rigidity and tenderness in the right hypochondrium. January 25, the day following admission, the operation was performed, the anæsthetic selected being nitrous oxide gas, followed by ether. The abdomen was extremely fat. Adhesions present, but not very troublesome. The gall-bladder tense and apparently in danger of bursting on manipulation. Tension was relieved by aspiration, and then, after manipulating some cystic duct calculi back into the bladder, the entire organ was removed, the wound drained and closed by suture of the peritoneum and fascia, and the edges of the skin incision approximated by sterile zinc-rubber plaster. The illustration shows specimen. It has been turned inside out so as to show the changes in the mucous membrane. There are ulcerations and patches of gangrene, and one may see with great distinctness the bed which these stones have made for themselves in the mucosa, and can easily understand how such constant irritation as must have been here present, may be the direct cause of malignant change. The stones are faceted, and at least, in their outer portion, are of cholesterin. The entire viscus was filled with fully four ounces of grumous pus. I can recommend this method of preserving the gall-bladder for observation and study.



The patient was a very sick woman for many days on account of a severe bronchopneumonia with myocarditis. She was finally discharged well on March 5, thirty nine days after the operation.

Case V.—Esther W., thirty-five years of age, and an old sufferer from pure cholelithiasis with no signs of acute infection, was admitted to my hospital service last autumn for operation. She had never had fever, but for years had suffered from almost daily gall-colic. Stones had occasionally been passed by the bowel. On October 18, I made a small incision through the right rectus, and on digital exploration found a thin-walled rather contracted gall-bladder containing stones, the ducts being apparently empty. Because there had never been fever, in spite of the numerous attacks of colic, and because the walls of the viscus felt thin and absolutely normal, I merely incised it at its fundus, and after removing six stones as large as small hazelnuts I sutured the opening in the gall-bladder and then closed the abdominal wall in the usual manner, leaving a very small drainage opening. In eleven days the patient left the hospital perfectly well.

This is the so-called ideal cholecystotomy. Its application is extremely limited, since it is suitable only in cases like the one just recounted. If there is a suspicion of infection within the gall-bladder the operation is unsurgical, and should be set aside in favor of cholecystotomy with drainage or better yet, cholecystectomy.

Case VI.—The patient, Mrs. R. K., fifty-six years old, was referred to me by Dr. Alfred Meyer, who had examined her for the first time less than twenty-four hours before. The previous history throws no light upon the case. For three and a half days the patient had had complete intestinal obstruction, not yielding to usual cathartic measures. Then there came severe right hypochondriac pain without chill, but with constant vomiting, becoming intestinal in character. Her pulse rate was 86, the respirations 40, and the temperature 100.5°. The tongue was dry and the face drawn. No icterus. The abdomen was somewhat distended, and individual coils of intestine could be made out. The entire picture was one of intestinal obstruction, with the probability that it was due to a constricting neoplasm of the large intestine with acute symptoms, caused by inflammatory œdema, with complete closure of the lumen of the gut. An incision was at once made (February 23, 1902) in the right upper iliac region, with the idea that a colostomy at this point would relieve the obstruction and tide us over the present emergency. On opening the abdomen collapsed transverse colon and distended cæcum were encountered, an adhesion in the neighborhood of the tense and distended gall-bladder being the obvious cause. The adhesion was divided and the obstruction relieved. The gall-bladder being evidently the seat of serious acute disease, I fastened it in the wound by a few stitches, and drained it of its foul-smelling pus. Two or three days afterward I removed two large calculi through the cystotomy wound, and the patient is now convalescent.

Removal of the gall-bladder would have been the more radical procedure here, but the patient's condition was such that the risk would have been unwarranted. Let me call attention to the fact that we have here an example of true intestinal obstruction, directly caused by adhesions from cholecystitis.

Case VII.—Mrs. B., fifty-six years old, had for years been afflicted with what had been pronounced as gastric trouble. In September, 1901, she came from her home in the West to consult Dr. Manges, having for a number of weeks suffered almost continuously to such a degree that she had to be kept for the greater part of the time under the influence of opiates. She had lost much weight, no doubt partly due to the fact that she was unable to retain food taken by mouth. There was considerable jaundice, and a tender tumor could be made out in the right hypochondrium. The diagnosis of obstructive jaundice probably due to gallstones was made, and the patient was referred to me. Exploration was performed on October 18 through an incision through the right rectus, when it was found that the tumor consisted of a large right hepatic lobe. The gall-bladder was much contracted and contained stones which were not removed at the time, because there were a number of large nodules in the liver which looked cancerous. The wound was accordingly left open for a secondary cystotomy, if advisable, and a piece of one of the masses removed for examination. It proved to be carcinoma, so nothing further was done. The patient lingered for a number of weeks and died asthenic. A post-mortem examination revealed stone in the gall-bladder, with carcinoma primary in that organ and with many metastases. One large mass simulated during life an enlarged and tense gall-bladder.

This case illustrates the course of malignant degeneration following cholelithiasis, probably quiescent for years.

My list will close with the following brief reports of three cases which I may term ideal cholecystectomy, *i. e.*, cases in which the operation was performed before the supervention of cholecystitis, adhesions, and jaundice.

CASE VIII.—Mr. R., a gentleman fifty years old, in the practice of Dr. Walter Brickner, had repeated typical attacks of biliary colic. Cholecystectomy January 16, 1902. One large stone in the cystic duct was milked back into the gall-bladder, which contained five others, about as big as cherries, and several minute ones. Viscus about as large as half a small sausage. Discharged from the hospital February 9 after an uneventful recovery.

CASE IX.—A most unusual case. Cholecystectomy for cholelithiasis in a child eleven years old. Erma, J. W., a patient of Dr. W. W. Talley, had been troubled with attacks of jaundice at frequent intervals from her sixth year. The first attack came on after whooping cough. Jaundice usually lasted about two weeks. From her eighth year the child began to have colic preceding the icterus, and for a number of months before I saw her, the colicky attacks had become extremely frequent so that the girl's skin was never of a normal color. I made the diagnosis of cholelithiasis, which was concurred in by Drs. Talley and I. Adler. On February 22 of this year I operated, removing a thickened and rather large gall-bladder containing a number of irregularly shaped pigment stones. There was no infection of the surrounding tissues and the operation was easily performed, the gall-bladder peeling with facility from the liver. The convalescence was absolutely normal and the patient was discharged from the hospital on March 9.

CASE X.—Mrs. S., thirty years old, patient of Dr. Adler, was operated upon for cholelithiasis with frequent colicky attacks. The operation was performed on March 4 of this year, in interval between attacks. No adhesions complicated the case and the gall-bladder, containing a number of calculi, was quickly and easily removed. At the present writing, March 22, two and one-half weeks afterward, the wound is entirely healed and the patient is kept in bed merely to insure the firmness of the cicatrix.*

Cholecystectomy, then, may be considered, other things being equal, the most radical treatment at our disposal for the cure of cholelithiasis. The operation devised by W. J. Mayo[9] is the next best thing. It consists in the evisceration of the mucous membrane of the gall-bladder and is practiced when irremovable adhesions forbid the safe extirpation of the entire organ.

The postoperative course of a case of cholecystectomy is, as a rule, far less annoying to the patient and much simpler for the physician than the postoperative course of cholecystostomy with drainage. Then, too, the trouble from adhesions is much less after the clean removal of the gall-bladder than after cholecystostomy with fixation of the gall-bladder to the abdominal parietes. This latter condition has, in my experience, not infrequently been a source of considerable pain and distress from the dragging upon the liver.

It might be suggested that in the event of the formation of calculi in one or another of the ducts after cholecystectomy further operative measures might be rendered somewhat more troublesome on account of the absence of an important landmark. I can but say, however, that if this ever occurs it must be extremely rare, and should surely not be regarded as a serious surgical objection.

The gall-bladder has, perhaps, a function. I do not think that it has ever been discovered, but whatever it may be, the preservation of the infected organ can scarcely overbalance the advantages of the radical cure of a distressing and serious disease.

[illegible] MADISON AVENUE.

---

* Ten days later this patient was discharged, the wound soundly healed.

The Etiology and Treatment of Obesity.—Professor Debove says that in order that a person may lose weight he must be put on an insufficient diet without, however, allowing him to suffer from hunger or from the slightest constitutional disturbance. To assuage hunger all we have to do is to resort to aliments possessed of low thermic value, even when given in large quantities. He usually orders milk, preferably skimmed, mixed with water or tea, green vegetables and fresh fruit. Persons fed on fresh vegetables, raw meat, etc.—in fact, on what might be called living substances, are much better able to support an insufficient diet than others. The patients are allowed to drink as much water as they wish. Great care is taken to keep the bowels freely open. The author reports cases which demonstrate the value of his method of treatment.—*Medical Press and Circular.*

A Case of Tetany in an Adult.—Edwin A. Locke reports a well-marked case in a man of thirty-six years. The disease is relatively so infrequent in America as to be worthy of record. There was a striking absence of all the commonly recognized causes, but there were prolonged muscular work, fatigue, alcoholism, and exposure to cold and wet, which are usually mentioned as occasional causes of the disturbance. The condition was easily distinguishable from epilepsy, the muscular spasm of cerebral congestion, and hysterical conditions. Of especial interest in this case were the presence of polyuria and albuminuria during the attack, but few cases of either condition having been recorded. They are much more frequently found in children than in adults.—*Boston Medical and Surgical Journal.*

ACROPARÆSTHESIA (THE PARÆSTHETIC NEUROSIS); THE ANALYSIS OF ONE HUNDRED CASES.

By JOSEPH COLLINS, M.D.,
PROFESSOR OF NERVOUS AND MENTAL DISEASE, POST-GRADUATE MEDICAL SCHOOL; VISITING PHYSICIAN, NEW YORK CITY HOSPITAL.

It often facilitates the clinical recognition and pathological interpretation of a symptom to describe it in as much detail as if it were a disease. In this way its frequency, its association, its relationship to age, sex, occupation and environment, its duration, modes of onset and termination, may be determined. Our knowledge of headache, for instance, has been obtained largely in this way. The same is true of neuralgia, of delirium, of insomnia, all of which are symptoms, but which are commonly considered as entities in our textbooks.

Acroparæsthesia is comparatively a new term, having been introduced by Schultze of Bonn in 1893. Its significance is clear from its etymology. *Acros* is Greek for extremity, and paræsthesia a compound Greek word, signifying abnormity of sensation. Acroparæsthesia is, therefore, the term used to indicate abnormal sensation of the extremities, the sensations characterizing it being principally those of pricking, tingling, stinging and subjective numbness.

Attention was first called to the symptom-complex, now designated acroparæsthesia by Putnam of Boston in 1880. He stated that patients with this disorder presented a disturbance of the subjective sensibility of the skin, giving rise to what is popularly known as numbness, recurring periodically, coming on especially at night, or early in the morning, and affecting one or both hands, either alone or in company with the arms, the legs, or, rarely, the entire body. Putnam cited a number of typical instances of the affection, and gave an analysis of thirty-one cases which had up to that time come under his observation. His description of the condition was so accurate that little has been added to it. In 1885 Dana of New York, in an article on the acroneuroses, called attention to the same symptom-complex, and gave an analysis of twenty-eight cases. In this article particular attention was given to the morbid dependency of the condition. In the same year Saundby of London described it, and cited a number of illustrative cases. Despite these contributions the subject attracted little attention until Schultze, and afterwards Laquer of Frankfort-on-Main, in 1893, wrote their papers; the former giving to it the name by which it is now commonly known.

This neglect of the writings of two American neurologists has apparently given rise to a mistaken belief on the part of some writers, especially some German writers, as to who was the first to describe it. In the latest monograph in which the subject is treated, "Herzneurosen," by A. Hoffman of Düsseldorf, is found the astonishing statement (which, however, is not original with him) that until the article of Schultze the clinical picture was not generally recognized. This can only be true of *some* of his countrymen, for Schultze was familiar with the contributions of the writers above mentioned, as well as those of Ormerod, Bernhardt, Berger and others, who wrote upon this and allied paræsthesias, and he discussed them, fundamentally, in the article in which the term acroparæsthesia was first used.

In September, 1893, I published an article on the subject in the *Boston Medical and Surgical Journal*, under the title of "The Paræsthetic Neurosis," which was based upon a study of forty-three cases previously observed. In the same year Friedman of Mannheim analyzed and commented upon eight cases, while in the following year Sinkler of Philadelphia recorded his experience. Since that time the subject has not been much studied, save by Gallois, and by Charbo, the latter having devoted his inaugural thesis to it. Within the past two years, Edgeworth and Savill, in England, have published some cases, the latter attempting a classification of it, with other acroneuroses, but withal comparatively little attention has been given to the matter.

When I published my first article on this subject it seemed to me that there was a fatigue, or an intoxication state, of the nervous system, manifesting itself through the peripheral sensory nerves, whose chief symptom was paræsthesia of the extremities, which might be thought of as a clinical entity, and called the paræsthetic neurosis. Further acquaintance with the condition has convinced me of the unadvisability of considering it as a disease in the majority of instances, while at the same time it has corroborated the opinion then expressed as to its occurrence, morbid dependency, course and termination. I now look upon acroparæsthesia as a symptom, or symptom-complex, in the same way that I look upon headache or neuralgia, and it may be associated with or dependent upon as great a variety of causes. It is a symptom-complex which I seem to encounter every year with greater frequency, especially in my clinic, and for this reason I am prompted to again call attention to it. During the past five years the diagnosis of acroparæsthesia has been made one hundred times in my clinic, and it is from the records of these cases that the statements herein as to the causation, symptomatology and treatment are made. Attention is called to the fact that this diagnosis is never recorded when the symptom-complex of acroparæsthesia is associated with and, therefore, inferentially dependent upon such diseases as neuritis, rheumatism, gout, or other arthritic conditions, diabetes, pulmonary tuberculosis, or conditions commonly looked upon as surgical, such as flat foot and trigger finger. In a similar way clinical histories are not labeled "headache," even though this is the prominent symptom, when the disease is pachymeningitis, intercranial syphilis, or glaucoma. Paræsthesia of the extremities is a symptom of a number of diseases—for instance, any of those mentioned above, but it is not of these that I write. In some of these cases recorded as "acroparæsthesia" there may have been one of the conditions mentioned above with which paræsthesia of the extremities is associated. If so it could not be detected. In other words, the diagnosis was made only when the acroparæsthetic symptom-complex was the only manifestation of disease. There are many reasons for looking upon acroparæsthesia of this sort as a disease and not a symptom—that is, for considering it a fatigue or exhaustion state like neurasthenia, and I see no possible objection to so interpreting it—a symptom in some instances, a neurosis in others. Possibly it is oftener a symptom, pure and simple, than we believe, and that if we could recognize the earlier stages of arterial fibrosis and the lighter grades of perineuritis and sensory neuritis this form would still be commoner.

To call attention to the clinical picture of acroparæsthesia, I shall cite a case in detail, an unselected history, the last one recorded of the one hundred cases:

A widowed dressmaker, thirty-six years old, relates that last summer, while at Atlantic City spending her holiday, she first observed that soon after retiring, especially after she had got partly or wholly asleep, she was aroused by most disagreeable and painful sensations in both arms and hands as if both upper extremities had gone "asleep." She would open and shut the hand vigorously a few times, beat and squeeze the forearms "to make the blood circulate again," and finally the paræsthesia would gradually disappear. Then she would fall asleep, but only to be awakened in a similar fashion, this occurring, perhaps, half a dozen times during the night, and almost invariably in the early morning. On arising in the morning, she felt as if she had been strained "from the shoulders," and was, of course, unrefreshed. So far as she knew, the only thing that would provoke an attack of paræsthesia at once was to lie down with the hands extended above the head. She had fallen into the habit of clutching the sides of her nightdress when she retired, so as to keep her hands from straying upward. The attack would occur, however, with the hands in the latter position, but not so frequently. No cause could be attributed for the occurrence of the attacks, save that she was overworked and felt run down. Treatment, consisting of tonic baths, overfeeding, enforced rests, adoption of a regime to overcome constipation, from which she had long suffered, a quiet life in the open air, dispelled the symptoms after a few weeks, and she remained free from them until toward the end of the following winter, when she began to complain of a similar sensation in the big toe of the left foot and in both groins. Occasionally, her hands and forearm "feel as if they are going asleep." The occurrence of these symptoms was contemporaneous with much more obstinate constipation than she had previously experienced, and with a feeling of loss of ambition and easily-induced fatigue. Examination revealed no objective phenomena of any description. Constipation is really the patient's burden. She goes on taking food until, as she expresses it, "her stomach will not hold another bit. Then she takes a cathartic.

This case may be taken as an example, which is, however, subject to great variation with different individuals. It is superfluous to say that no two patients with nervous disease describe their infirmities in exactly the same way, and to this rule acroparæsthesia offers no exceptions. Sufferers from this affection are usually in fair health, except for the paræsthesia. As has been said above, this paræsthesia consists of a tingling, stinging, pricking feeling of the extremities, especially of the hand, a sensation of "pins and needles" and formication (so-called "going to sleep" of the extremity), associated with more or less profound feeling of numbness, slight unwieldiness, and diminished dexterity. These sensations are not limited to the distribution of a single nerve, as when one strikes the ulnar nerve at the elbow, but they are apt to be most severe at the finger ends. The sensations vary in severity from slight disagreeableness up to severe pain.

Objectively, nothing is to be made out in the vast majority of cases. In a few instances, sensibility is slightly diminished, constituting hypæsthesia. There is no tenderness on pressure over any of the nerves, save in those instances in which it is dependent upon mild neuritis or perineuritis, and no perceptible atrophic or degenerative changes. In no instance have I been able to make out anything, even approximating, irregularity over the course of a nerve which would lead one to believe in the existence of minute growths in the sheath of the nerve, such as have been described by Friedmann. In the vast majority of my cases no changes in the color or temperature of the skin have been observed, either by patient or physician. The skin is often relaxed and clammy to the touch, and the pulse lacking in vigor, but there is no redness or crimson coloration suggestive of erythromelalgia, or paleness and blanching of Raynaud's disease. The affection comes on in attacks or paroxysms, most often at night, just after the patient has gone to sleep, or toward early morning. In some cases, perhaps in nearly one-half, the paræsthesia is troublesome during the day. It is much more likely to be complained of when the patient is at rest, however, than when actively at work. While the paræsthesia is present there is accompanying lessening of manual dexterity and ability, which is both subjective and objective, and in some instances after the paroxysm disappears there is complaint of weakness, or, as the patients often express it, of "stiffness" in the hands. This, however, is not evident to the observer.

Information concerning the etiology and detailed symptomatology from examination of these one hundred cases is as follows. For the statistical work of the report I am indebted to one of the assistants in my clinic, Dr. Wm. J. Dougherty of Yonkers.

Etiology.—*Age.*—Average age, thirty-nine, ranging from seventeen to seventy-nine years. Of the one hundred cases, twelve occurred between the ages of twenty and thirty, twenty-seven between thirty and forty, thirty-one between forty and fifty, eighteen between fifty and sixty, five after sixty, and only one under twenty years.

Sex.—Of the one hundred cases sixty-nine were females, and thirty-one were males. Of the females 65 per cent. were engaged in house or laundry work, 15 per cent. were needle workers, 10 per cent. were machine workers. The males were equally divided into tailors, laborers and "clerks." The latter designation may be construed to mean anything from a chevalier d'industrie to a hobo.

Nationality.—Thirty-four of the patients were Americans, forty-one Russians—all Jews—fifteen English, Irish and Scotch, ten Germans and French.

Previous Diseases.—In every instance the patient's previous health was inquired into. Ten of them had suffered from what they called rheumatism, but not rheumatic fever. Four had had the grip within the year from the onset of the paræsthesia. Several had had typhoid, pneumonia, pleurisy, and otitis media at a period remote from the paræsthesia. In none of the cases was there a history of syphilis.

Season.—The time of onset was recorded only in twenty-four cases. Of these eight occurred in the spring, eight in summer, and four each in autumn and winter.

Mode of Onset.—In regard to this point, also, many of the histories are not explicit, but in twenty cases in which it was noted the onset of the condition originally was sudden in fourteen instances.

Frequency of Occurrence.—Of 1,021 new patients treated at the clinic during the year 1901 seventeen cases were suffering from acroparæsthesia not associated with other disease. Thus its frequency compared with neurasthenia may be seen when it is said that during the same time 115 cases of the latter disease were diagnosticated.

Attributal Cause.—In the majority of instances, no cause could be attributed. The question was always asked, however, and the following were mentioned by the patient: Rheumatism, once; the grip, twice; pregnancy, twice; change of life, four times; menorrhagia, once; constipation, once; fright, three times; staying too long in bathing, once; miscarriage, once; and blood poisoning, once. Eight patients admitted the use of alcohol rather freely, and seven intemperate use of tea.

Symptoms.—*Location of the Paræsthesia.*—In 52 per cent. of the cases, the paræsthesia was confined to the hands or arms. In 10 per cent. to the feet or legs, and in 30 per cent. it occurred in both the upper and lower extremities. In 1 per cent. to the face. In 15 per cent. the paræsthesia, in addition to the extremities, occurred in other parts. In one instance it became general when the patient assumed a recumbent posture; usually, however, it confined itself to the upper extremities.

The Patient's Complaint.—Some pains were taken to transcribe the patient's exact designation of his symptoms, and they are here stated in the order of their recorded frequency. Numbness, sticking pain, tingling sensations, stiffness, creeping, crawling sensations, itching feeling, burning sensation, cold sensation, wooden feeling, swollen sensation.

Accompanying Conditions.—In this series, the most constant accompaniment was some disturbance of the gastro-intestinal tract. Constipation was noted in 32 per cent. of the cases, stomachic and intestinal fermentation in 10 per cent., and anorexia and coated tongue in 15 per cent. Eleven of the cases had marked neurasthenic symptoms and fourteen complained of headache. In one case, in which paræsthesia occurred in an individual afflicted with rheumatic arthritis, the symptoms of erythromelalgia occurred. In twenty cases the pulse was small, feeble, the extremities clammy, the circulatory tone low. Varicose veins were noted in three instances. There were no cases of sclerodactylia or of Raynaud's disease in the series. The symptoms were brought out or made worse by cold water in eight instances, hot water in four, damp weather in six, lying down in eleven, exertion in three, fatigue in five, menstruation in one. In 17 per cent. of the cases the patients complained of impaired dexterity.

Duration of the Condition.—The average duration was about fourteen months, ranging from one week to six years. In one case it is said to have existed for twenty-eight years, but this is not included in the average.

Study of these statistics shows that persons between thirty and fifty years of age are most likely to be affected. This is the period of greatest strenuousness, of financial and family anxieties, and the time when realization of one's limitations and infirmities comes as a burden and the vitality of youth is no longer there to counteract.

Men are oftener affected than has previously been supposed. In explanation of this it should be said that many of the males were tailors. All experience goes to prove that acroparæsthesia stands in close etiological relationship to occupations that produce fatigue and exhaustion of the upper extremities, such as that of tailors, dressmakers, embroiderers, etc., and those that necessitate keeping the hands in water, such as dishwashers and laundresses. It should further be said that nearly all the males were Jews of the lower class, who are notoriously predisposed to nervous disease, especially the functional varieties, and more especially to exhaustion and toxic neuroses. There can be no doubt, I believe, that in some instances this form of acroparæsthesia is a symptom of general or neuromuscular exhaustion, the same as headache, depression, sleeplessness and other familiar symptoms of exhaustion. In the cases that occur in laundresses and dishwashers it is probable that the paræsthesia is an expression of the vasomotor dilatation or paresis that such immersion invariably provokes.

Nothing of importance is to be learned from observation of the patient's nationality. The symtom-complex seems to occur in dispensary patients of all nations. Another noteworthy fact is, that so far as could be made out, the paræsthesia was not a sequel of any previous ailment.

Acroparæsthesia is occasionally, and, perhaps, often dependent upon changes in the walls of the bloodvessels. One of the common causes of arterial degeneration is syphilis, but none of our cases gave a history of luetic infection. I am inclined to believe that the cases of arterial degeneration accompanied with paræsthesia are of the very slowly progressive variety, with changes, predominantly, in the tunica media; not the rapidly progressive forms, with changes principally in the intima characteristic of luetic arterial degeneration.

Some writers on the subject are of the opinion that exposure to cold and inclement weather is responsible for the occurrence of the symptom-complex in some instances. My own conviction is that they have little or nothing to do with it, and the annotation in our histories relative to this point substantiates that belief. As a matter of fact, the occurrence of the symptom-complex is rarely attributable to any cause save overwork, although now and then a case is encountered in which tea drinking, the abuse of alcohol and tobacco, dyspepsia and constipation, seem to be the cause, and this is particularly striking because the paræsthesia disappears when they are overcome. The frequency of the symptom-complex is best conveyed by comparison with neurasthenia. About ten cases of the latter to one of the former come to the clinic. The diagnosis of neurasthenia is not made when any organic condition upon which the neurasthenia may depend is discoverable, even though the symptoms of this fatigue neurosis are most characteristic. Therefore the diagnosis of neurasthenia is not made nearly as often as formerly.

Study of the symptomatology does not reveal anything that has not heretofore been noted. Sometimes, but not as a rule, the paræsthesia develops suddenly. In upward of one half of all the cases the disagreeable sensation was confined to the upper extremities. In studying the grouped symptomatology it is quite noticeable that gastro-intestinal disorder was frequently present. Despite the coexistence of this and acroparæsthesia it is difficult to say that the latter is dependent upon the former. Theoretically, it is tempting to construe the acroparæsthesia as an end phenomenon of the dyspepsia, the intermediate stages being auto-intoxication, the poisonous matter acting directly upon the sensory nerves of the hands, highly predisposed by exhausting work, or indirectly upon the bloodvessels through the vasomotor nerves and the sympathetic system, and there is no doubt that this is the manner in which some of the cases do arise.

The pathogenesis of acroparæsthesia is practically unknown. Many theories have been formulated to explain its occurrence, but none of them has been proven. It is not likely that all cases are of the same pathogenesis. In fact, it is extremely unlikely that they are. In one instance the paræsthesia may be called into existence by an insufficient amount of lymph in the nerve sheaths, which is caused, in turn, by vascular disturbance: venous sluggishness, or insufficient arterial blood. This explanation would seem to be adapted to those cases in which the paræsthesia occurs in a person who sleeps with the hands extended above the head, and in those in whom the paræsthesia is induced by holding the hands in cold water for a length of time. In another instance the paræsthesia may be looked upon as an autotoxic manifestation, the poisoning arising in the alimentary canal, with constipation. Of course, we do not know why the sensory nerves of the extremities should be singled any in assigning this occurrence, nor do we know why such manifestation should be paroxysmal, but neither do we know why intestinal indigestion often causes paroxysmal headaches. Broadly, the paresthesia may be a manifestation of disorder from fatigue, exhaustion, or intoxication of the sympathetic nervous system. The symmetry of its distribution, its localization in the extremities, its paroxysmal occurrence, its tendency to recurrence, and its occurrence in neuropathic individuals all speak in favor of this view.

As a matter of fact, it seems to me that we may infer something in regard to the occurrence of the particular form of paresthesia that we are describing from those varieties that are symptomatic of more readily detectable conditions, such as arterial fibrosis, mild forms of multiple neuritis, which do not extend as far as true inflammation of the nerves, tabes, cervical pachymeningitis, etc. The paresthesia that is an accompaniment of some cases of arterial sclerosis, and which occasionally is a herald of an apoplectic attack, is not unlike that of acroparesthesia, save that it is not so liable to paroxysmal occurrence and is usually not so annoying. But so far as the patient is concerned, it is the same kind of a feeling, and, therefore, it may be that some of the cases of acroparesthesia that we are describing may be induced in a similar way.

Treatment.—By all means, the most important element in the treatment of these cases is the removal of the cause and the treatment of any accessory condition which it may have produced. In other words, if constipation exists, it is necessary not only to overcome that, but to counteract the effects which it has had upon the general nutrition. An investigation of the patient's mode of life and occupation will often reveal the factors that are apparently the excitants of the paresthesia, although removal or avoidance of them does not always succeed in overcoming it, even though it be combined with a tonic and restorative plan of treatment. Prolonged rest, nourishing diet, and new environment are the requirements for a speedy and complete cure. This is scarcely possible but for a few. For the majority, a compromise must be made, for often no one of these is possible. Tonic hydrotherapy, the cold splash bath, or half-bath, at a temperature of from 75° to 65° F., followed by vigorous frictioning of the skin, especially of the spine and abdomen, regulation of the diet, and especially increase in frequency of taking nourishment, enforced rest, such as lying down for a half hour or an hour at noon time or before supper, and the administration of such restoratives as iron, arsenic and strychnine, will, if persisted in, suffice to relieve this condition in the majority of cases. Such treatment is within the means of even the most humble. The paresthesia can be temporarily relieved by the use of bromides and other sedatives, such as phenacetin, but it is extremely unadvisable that these should be given, save except occasionally for a few doses, as their repeated administration contributes to depreciation of vitality. The use of electricity has been attended with gratifying results in a number of instances, both the galvanic and the Franklinic currents. The former in the shape of galvanization of the cervical and brachial plexuses, the positive pole over the latter, applied in labile fashion, the negative pole against the sternum, a current of five milliamperes being allowed to flow for about ten minutes. In sensitive patients the current over the neck must be somewhat weaker. The static current, both in the shape of the direct spark and of the hyperstatic current, has seemed to give relief to some of the patients, and, judging from the regularity and frequency with which they come to me for its administration after they have received it a few times, it is a grateful therapeutic measure, even though these same data do not speak convincingly of its curative qualities. When the attacks occur in the early hours of the morning, I have seen gratifying results attend the taking of a small quantity of trional or sulfonal, administered with hot milk on retiring. Occasionally treatment directed immediately to the overcoming of the uric acid diathesis, indigestion, constipation, and anemia, seems to be sufficient, but in the majority of instances there is needed in addition some such plan of treatment as that which is successful in the ordinary cases of neurasthenia. Some cases resist all treatment and finally get well spontaneously, as it were, while others recur whenever the general health or vitality is let down and disappear again when the individual regains normal health.

32 West Thirty-eighth Street, New York City.

THE SYMPTOMS OF CHRONIC NON-ALCOHOLIC GASTRITIS

By GEORGE ROE LOCKWOOD, M.D.
NEW YORK
ATTENDING PHYSICIAN TO BELLEVUE HOSPITAL

The cases upon which the following report is based are of chronic non-alcoholic gastritis occurring consecutively in private practice only. The diagnosis in each case has been verified by gastric analysis, which has been frequently repeated in the majority of instances. As the patients came under observation they were entered in long case-books with cross-rulings for checking off the presence or absence of symptoms, and it is from these case-books that the following data have been obtained. When the symptoms so presented are compared with those we would be led to expect by reading the existing textbooks of general medicine on the subject, we notice a most radical difference, and it is the object of this paper to show how great is this difference between the clinical course of chronic gastritis in actual practice and that which exists on a literary basis. Upon analyzing the symptoms it becomes evident that the cases can be divided into three groups according to the degree of gastric secretion: (*a*) cases of hyperacidity; (*b*) cases of normal acidity; (*c*) cases of diminished acidity. In each group there also seems to be a natural division into the cases with atony and those without. A practical clinical grouping, therefore, of cases of chronic gastritis would then be as follows: (1) Hyperacid cases without atony; (2) Hyperacid cases with atony; (3) Normal acid cases without atony; (4) Normal acid cases with atony; (5) Anacid cases without atony; (6) Anacid cases with atony. The total number of cases upon which the report is based is forty-six.

Hyperacidity without Atony—Ten Cases.—Of the actual symptoms presented in this group only four gave symptoms referring to the stomach, and in these the symptoms were those of acidity only.

Case I.—Male, thirty-eight years old. Following a sunstroke eighteen years ago, patient has noticed acidity of the stomach, requiring constant use of soda. This symptom, at first intermittent with long periods of freedom, has, for the last five years, become constant. The appetite is good, and he suffers neither from pain, nausea, vomiting, or gas, but is well nourished, and not anæmic. The fasting stomach was of normal size and of good muscular power, and contained in the fasting condition 30 c.cs. of bile-stained mucus, without acidity, and without food remains. Test—

breakfast gave 170 c.c. of foodstuff, containing large masses of mucus; total acidity, 96—free HCl. 80; combined HCl. 8.

Case II.—Male, twenty-eight years old, who, since an accidental ammonia poisoning five years ago, has suffered from acidity two hours after meals and feels "gone" on an empty stomach. These symptoms are relieved immediately by eating or by taking soda. There are no other symptoms referred to the stomach, and the patient is well-nourished and not anæmic. The stomach is of normal size; its muscular function varies between hypermotility and temporary atony, according to the reaction which fatigue, loss of sleep and nervous strain makes upon an impressionable nervous system. The fasting stomach contains 30 to 40 c.c. of bile-stained mucus without acidity. The test-breakfast shows a total acidity of 56 to 84, and lavage brings a large quantity of glairy mucus. Indican is present in the urine in abnormal quantities.

Case III.—Female, forty-five years old, who has complained for one year of gnawing feelings on an empty stomach, relieved by eating and by soda. There are no other symptoms, and the patient is well-nourished and not anæmic. Stomach of good size and of good muscular power, contains in the fasting condition 40 to 60 c.c. of neutral mucus. Test-breakfasts show moderate hyperacidity of 60 to 70, with large quantities of lumpy mucus.

Case IV.—Male, forty years old, who for eight years has had hyperacidity; better in summer when he gets exercise, and worse in winter. The patient is never without his soda mints, taking them regularly two or three times between meals and several times during the night. The appetite is good and, except for the acidity, there are no other symptoms. The patient is well-nourished and not anæmic. The stomach is of normal size and of normal muscular power. Lavage brings large quanities of glairy mucus. Test-breakfasts show a total acidity of about 86. By treatment of the gastritis, the acidity has disappeared.

In these four cases there is a well-marked similarity. In all, acidity was the only symptom, and was largely under the control of the nervous system in all, being more prominent whenever the patients were tired or nervous. They might well have been considered cases of nervous hyperacidity; in fact, three were so treated at the start.

It is important to remember in this connection that an inflamed stomach is, if anything, more apt to be neurotic than a healthy stomach, so that a gastric neurosis may well be ingrafted on an organic affection.

The feeling of the writer is that long-continued gastric neuroses are exceedingly rare unless engrafted on an organic basis, and that in all cases of prolonged so-called neuroses, gastric analysis should be made. In the treatment, moreover, both elements—the organic and the neurotic—should be considered.

Three of the cases gave well-marked intestinal symptoms, forming a distinct clinical group.

Case V.—Male, forty-three years old, for three months has suffered from diarrhœa, having from five to twelve loose stools daily, without blood or mucus. During this time has lost twenty-seven pounds, and looks as if he had cancerous cachexia, being sent, in fact, to the writer with the diagnosis of malignant disease of the colon. The diarrhœa, while checked temporarily by drugs, rapidly returns as severely as before. The appetite is good. There is neither pain, nausea, nor vomiting nor gas on the stomach, but as eating regularly increased the diarrhœa, he has most rigidly over-dieted, a fact that has contributed materially to his loss of flesh and strength. Examination showed normally located colon, of normal muscular power and without evidence of catarrh. Microscopical examination of the stools being, moreover negative, it seemed improbable that any intestinal lesion existed. Repeated examination of gastric contents showed a constant hyperacidity (total acidity 70 to 85), with a large amount of mucus, both in the test-breakfast and in the fasting state. Under full diet with food between meals, and small doses of bromide to check the excessive peristalsis, the diarrhœa stopped in two days, the flesh and strength returned, and for a year the patient has remained perfectly well.

Case VI.—Male, forty-three years old, for two years has had every morning a loose, painless diarrhœal stool. Aside from a sense of fulness in the central abdominal region after meals, there are no other symptoms referable to the digestive tract. Examination shows the colon normal in position in muscular power, and free from catarrh. Gastric analysis revealed a well-marked catarrhal inflammation of the stomach, with total acidity of 70. The symptoms ceased in two weeks by taking soda between meals, and for four months have not returned.

Case VII.—Male, fifty-six years old, for four months has had a more or less steady pain in the right iliac fossa, with one or two loose movements with considerable gas. There is no abdominal tenderness and the leucocytes number 5,800. During this time the patient has lost twenty-five pounds, and looks almost cachectic. Palpation of the abdomen failed to detect any abnormalities. The functions of the colon were normal, and evidences of catarrhal colitis were not found either by irrigation or by microscopical examination of the stools. Gastric analysis showed a marked gastritis, with a total acidity, ranging from 80 to 94, with hypersecretion. The urine contained an excess of indican. The patient was put upon soda in full doses between meals and within a week the symptoms disappeared, and in three months there was perfect return of flesh and strength.

In these cases the symptoms seemed due to an increased intestinal peristalsis, caused by the irritation of the small intestine by too acid chyme. The stools all had the appearance of small intestine stools, and contained neither mucus nor blood. Neither was there any other sign of abdominal lesion. The symptoms were rapidly and permanently relieved by antacid treatment. All three patients were under-nourished and anæmic, and their appearance suggested cancerous cachexia, and, in fact, two of the three being referred to the writer with this diagnosis. It is moreover interesting that not one of them gave a single symptom pointing to the stomach. Two cases gave symptoms of recurring bilious attacks without a symptom that drew attention to the stomach.

Case VIII.—Male, forty years old, for six months has suffered from discomfort and feeling of fulness in the bowels several hours after eating. During this time he has been somewhat constipated. He feels weak and nervous, has congested feeling in the head. with a coated tongue, and malodorous breath, and from time to time complains of "bilious attacks," of vomiting, and headache. Analysis showed mucous gastritis, and an acidity of 95.

Case IX.—Female, forty-two years old, for years has suffered from sick headache, induced by taking an ordinary amount of wine at dinner, or by being overtired. There are no other digestive complaints.

Analysis shows mucous gastritis, with a total acidity of 64.

The explanation of these cases seems to be that the upper intestine becomes congested by the liver and chlorine, and that the symptoms are due to a resulting toxæmia. The writer has been very skeptical as to the existence of a primary functional disturbance of the liver, but believes that these cases are practically intestinal toxæmias, and that the action of calomel is simply to carry off poisonous intestinal products. Further, that in every case of "biliousness" or recurring "bilious attacks" a careful examination of gastric contents should be made, and that the primary seat of the liver disturbance will almost always be found in some well-marked change in gastric chemistry.

One case of the series gave only a history of extreme lassitude in attacks lasting about two weeks, with vague symptoms of abdominal distress. In this case a course of Wiesbaden water brought about a good and permanent result.

Of the ten cases of hyperacid gastritis without atony only one gave nausea as a symptom, and that occurred only at times when he was tired, and had not had a proper amount of sleep. The cause for nausea in this case was proven to be a temporary atony, as shown by a large amount of residual lavage water at these times, and by other ordinary signs of this condition. Pain occurred only once and that was the pain of acidity, occurring before meals and being relieved by eating and soda. Flatulence was not noted in a single case. In every case the appetite was normal or increased. Vomiting did not occur in a single case.

II.—Hyperacidity Cases with Atony, Eleven Cases.—Case I.—Male, thirty-five years old, sixteen months ago noticed "churning" feelings in the intestines on lying down at night. During the first week there was considerable diarrhœa, followed by constipation, lasting till date. The churning feelings have continued, and he is annoyed by the constant presence of gas in the stomach and bowels. The fasting stomach contains 50 to 80 c.c. of mucus and liquid of total acidity 50 to 70, no food remains. Test-breakfasts show well-marked mucous gastritis, and an acidity ranging from 72 to 98.

Case II.—Female, sixty years old, all her life has had "burning acidity," and is always taking soda. She has required laxatives for years. Aside from an occasional dizzy attack, there are no other symptoms. Gastric analysis shows mucous gastritis with an acidity of 70. Moderate atony by the ordinary tests.

Case III.—Male, forty-eight years old, has suffered from constipation, with gastric and intestinal flatulence for years. There are no other general or local symptoms. Analysis shows mucous gastritis, with an acidity of 60 to 70. The colon is atonic and the seat of a moderate catarrhal inflammation. Under treatment for the gastritis the symptoms improved and for one year the patient has remained perfectly well.

Case IV.—Female, thirty-nine years old, for thirteen years has suffered from constant flatulence in both stomach and bowels. The bowels are regular, the appetite good, there is no distress after eating, except an occasional attack of acidity. The fasting stomach contains 85 c.c. of mucus, with an acidity of 26, composed entirely of free HCl. The test-breakfast is imperfectly digested, and mixed with a large amount of mucus and of an acidity of 80. The colon is atonic, but neither catarrhal nor displaced.

Case V.—Female, twenty-four years old, for one year has complained of pain in the stomach of a cramp-like character, evidently due to flatulence. There has also been a gnawing pain before meals, relieved by eating or by soda. The bowels have been obstinately constipated, and there has been constant intestinal flatulency. The general health has become much impaired, the weight gone from 145 to 115 pounds in this time, and for ten months the patient has not menstruated. The stomach was found to be atonic, the greater curvature reaching a finger's breadth below the navel. The examination of the fasting stomach was negative. Test-breakfast showed semi-digested breadstuff admixed with masses of mucus, and of a total acidity of 64. The colon was atonic, neither displaced nor catarrhal. By appropriate diet and applications of intragastric faradism, and bodily rest, the weight was increased to 131 pounds in six weeks, the neurasthenic symptoms rapidly disappeared, menstruation returned, and for a year has been perfectly regular.

Case VI.—Male, twenty-six years old, for three years has complained of fairly constant acidity, and of gas in the stomach and bowels, and constipation of a pronounced spastic character. He is nervously depressed and has very little appetite. There are no other general or local symptoms. The stomach is normally located, but atonic, and contains a large amount of slightly acid mucus, in the fasting condition. The test breakfast is semi-digested, contains a large amount of mucus, and is of the total acidity of 72 to 80. The colon is in a spastic condition, but shows no colitis.

Case VII.—Female, twenty-six years old, for two years has suffered from gastric flatulence, acidity of the stomach about two hours after meals, and occasional attacks of severe pain, evidently due to pyloric spasm. Neurasthenic symptoms, or, more properly speaking, toxæmic symptoms, such as flushings of face and insomnia, are present in great variety, and to a distressing degree, associated with attacks of great mental depression. The urine is reduced 20 to 25 ounces a day, and contains an excessive amount of indican. The stomach is atonic, the greater curvature lies a finger's breadth below the navel, and contains a large amount of mucus in the fasting state. The test-breakfasts are semi-digested, and contain much mucus, and are of the total acidity of 66 to 75. The colon is normal in all of its functions.

Case VIII.—Female, twenty-six years old, for several years has suffered from the feeling of lump in the stomach, relieved by raising gas, and from time to time is obliged to take soda mints. The bowels are obstinately constipated, and every few weeks there are passed long strings of mucus, with griping abdominal pain, a typical membraneous colitis. Between these attacks the colon washes clear, but a moderate coloptosis is revealed by inflation. The stomach lies one inch below the navel, and is moderately atonic. The fasting stomach contains mucus. Test-breakfasts show semi-digested foodstuff, glairy mucus, and a total acidity of 66.

Case IX.—Female, forty years old, for years has suffered from constant headaches of varying character, gas in the stomach and heartburn. The patient is hysterical, introspective, and is constantly taking a great variety of headache powders. The general condition is poor, the bowels are constipated. The fasting stomach contains a large amount of mucus. Test-breakfast is semi-digested, comingled with tenacious mucus, and is of a total acidity of 76. The colon is normal.

Case X.—Female, thirty-five years old, complains of "gnawing emptiness," relieved by soda and by eating, with gastric and intestinal flatulence.

There are occasional pains referred to the stomach, evidently due to gaseous accumulation. When tired, there is some nausea, which has a relation to eating, but which does not interfere with a normal appetite. The patient is anæmic, neurasthenic, and poorly nourished. The stomach and colon are both displaced, together with the right kidney. The fasting stomach is free of mucus, the test-breakfast is semi-digested, contains a large amount of mucus, and is of a total acidity of 80.

Case XI.—Gave only the symptoms of recurring bilious attacks, and a moderate anæmia, no other symptoms whatever. Analysis shows mucous gastritis of a total acidity of 66.

Although these ten cases gave symptoms referable to the stomach, and all gave positive proof by gastric analysis of the presence of mucous gastritis, the grouping of symptoms, gas acidity and constipation, is not at all characteristic of gastritis. A similar picture is afforded by atony alone and by gastroptosis. Simple atony gives exactly this picture, while gastroptosis with atony is varied only by the greater prominence of neurasthenic and subnutrition symptoms. Subnutrition seems to be rare in uncomplicated gastritis. Of these eleven cases only four were under-nourished. Of these four cases two were complicated by gastroptosis—both of these had over-dieted. The third case had over-dieted and gained twenty-seven pounds in four weeks after more liberal nourishment. The fourth case was an hysterical woman, who ate most irregularly and lived on drugs.

Although gastroptosis is to be suspected if subnutrition or neurasthenia be markedly present, the diagnosis can only be made by a careful examination of the size and position of the stomach, and of the gastric contents.

The question of food retention is interesting in connection with gastric fermentation. Gas was a marked feature in all but two cases.

While in these cases a delayed food-exit was usually present, it was noticed that test-breakfasts, as well as gastric contents, removed four to five hours after a regular meal, did not differ from those obtained in the non-atonic cases.

Sarcinæ were not found in any of the cases, nor were the yeast-fungi increased. Further, these gastric-contents did not ferment even when mixed with starch or sugar solutions and kept at a blood temperature in a bacterial box.

A large number of experiments were made to demonstrate this point.

In each case 10 c.c. of gastric contents were placed in a bottle having a tight cork, through which a glass tube was passed leading into an inverted water-filled test-tube, so that the gases could be collected. This apparatus was kept in a bacterial box at a temperature of 104°. Similar quantities of gastric contents were mixed with an equal amount of thin starch solution and with an equal amount of syrup. It was also proven that the apparatus was air-tight.

In a few instances about 1 c.c. of gas was formed, but in the great majority of instances no gas at all could be demonstrated, although the mixtures stood for days. Specimens of gastric-contents come to the writer through the mail and arrive in perfectly good condition. Time is too limited to go further into the nature of the gas in these cases. It certainly seems as if fermentation in these cases was a myth. The writer's own theory is that nature, unconsciously to the patient, endeavors to neutralize the hyperacidity by the swallowing of alkaline saliva, and that the gas in these cases is simply swallowed air. This is corroborated by the fact that gas occurs more frequently in hyperacidity than in low acidity, in which fermentation should more easily occur.

Of these cases two had spastic colons, seven had atonic colons. In only three was colitis present and two of these had coloptosis.

It is interesting that while hyperacidity *without* atony gave a clinical group of diarrhœa and emaciation, not one of the cases of hyperacidity *with* atony gave diarrhœa as a symptom. This is probably due to a concurrent atony of the colon, preventing the increased peristalsis seen in the first set of cases.

Gastritis with Normal Acidity, without Atony, Five Cases.—Of these five cases not one gave stomach symptoms of any significance whatever.

Case I.—Female, thirty-two years old. For several years has been anæmic and moderately constipated. When tired may complain of a little nausea not related to meals, and may feel "gone" in the empty stomach. There are no other gastric or intestinal symptoms. Examination shows mucous gastritis, with normal acidity. The colon is normal.

Case II.—Female, eighteen years old. For ten years has complained of headaches, biliousness and torpid liver. Aside from a moderate constipation, there are no other gastrointestinal symptoms. Examination shows mucous gastritis, with moderate acidity. The colon is normal.

Case III.—Male, thirty-five years old. The patient is worried by small things and tires easily. There is no pain, nausea, vomiting, gas, nor loss of appetite. The bowels are regular. Despite the absence of digestive symptoms, examination reveals a mucous gastritis of considerable intensity. The total acidity is normal.

Case IV.—Male, thirty-five years old. Complains of constipation, attacks of faintness, and dizziness, and headaches like migrain, apparently toxic in origin. There are no other gastrointestinal symptoms. Examination shows marked mucous gastritis, with normal acidity. The colon is atonic but not catarrhal.

Case V.—Male, thirty-five years old. Complains of "bilious attacks." Has a feeling of lump in stomach all the time, except for a short time after meals, and which passes away after a few doses of bromide. Bowls regular. There are no other gastrointestinal symptoms. Examination shows well marked mucous gastritis.

Gastritis with Normal Acidity with Atony, Two Cases.—Case I.—Male, thirty year old. For three years has complained of a sense of weight in the epigastrium after eating. Not fairly constant. Gastric flatulence. He feels faint and gone on empty stomach. The bowels are constipated, alternating, however, with occasional sharp attacks of diarrhœa. The stomach is normal in size and position, but of poor muscular power. There is a well-marked mucous gastritis, with a total acidity of 52. The colon is in a spastic condition, but not catarrhal.

Case II.—Female, thirty years old. For five years has been anæmic, in spite of having taken more or less continuous treatment by iron. There are waves of faintness, independent of eating, and not interfering with a normal appetite. The stomach is atonic, and the greater curvature lies two fingers' breadth below the navel. There is a mucous gastritis, with an acidity ranging between 30 and 55. Under treatment by lavage and introgastic faradism the anæmia rapidly improved, and for two years the patient has remained perfectly free from symptoms.

These cases of normal acidity with atony gave no gastric symptoms except the loss of appetite with atony.

Gastritis Anacida Without Atony, Ten Cases.—Of these ten cases three gave intestinal symptoms only.

Case I.—Male, seventy-eight years old. Since an attack of cholera in 1849 has had intestinal cramps "seated in the bowels," and diarrhœa in attacks laying him up for several days every week or so. Between these attacks has one loose movement every morning without pain. Appetite good, the patient fairly well nourished, not anemic. There is no pain, nausea, vomiting, nor gastric flatulence. Repeated examinations for five years have never revealed a trace of acid nor of enzymes, zymogens active 1 to 10, inactive 1 to 20. In spite of the severity and long continuance of the case, there has never been a trace of gastric atony. Colon examination reveals atrophy of the mucous membrane which, interfering with water absorption from the colon, allows the loose daily stool. Under anacidity diet, and the pancreatin, the acute attacks have entirely subsided, and have not reappeared for three years, and the old gentleman is pretty hale and hearty for his years.

Case II.—Male, forty-three years old. For three months has complained of diarrhœa, cramps, and emaciation. The appetite is good, there is no gas, nausea, vomiting nor gastric pain. The colon is normal. Test-breakfast shows foodstuff semi-digested, with much mucus. Total acidity varies from 10 to 20. Diarrhœa ceased at once by lavage and Kissingen, and for one year has not returned.

Case III.—Male, fifty-five years old. For one year he has had one loose morning stool with considerable intestinal gas; there are no gastric symptoms. Examination shows mucous gastritis, with anacidity; the enzymes absent, zymogen active in 1–160 dilution. The colon is normal. Although the patient has been under medical treatment for one year without relief, the symptoms disappeared entirely in two weeks, by anacidity diet and Kissingen water, and has not reappeared. Of late there has been a return of the acid.

Two cases gave the history of bilious attacks alone.

Case IV.—Male, sixty-six years old. Since 1864 has had "bilious attacks," like sick headache, every few weeks. He has a moderate amount of intestinal gas, but none on the stomach. There is no pain, nausea nor vomiting. The appetite is good, the bowels are regular, there is no gas. The test-breakfast shows no trace of acid nor of enzymes; zymogen (rennet) is active in a dilution of 1–160. Under diet and Kissingen water has had no attacks for a year, there is, however, no return of the acid.

Case V.—Male, fifty-five years old. For fifteen years has complained of "bilious attacks," with headache, nausea, occasional vomiting, coated tongue and foul breath. Between these attacks he felt perfectly well till about two years ago, when he began to suffer constantly from headache, lassitude and general dopiness. The test-breakfast shows a total acidity of 16, a slight trace of butyric acid, no free or combined HCl., enzyme absent, rennet zymogen active in 1–160 dilution. His appetite is good; there is no pain, gas, nausea, nor vomiting.

Cases VI., VII. and VIII.—These cases gave simply loss of flesh and strength without gastric symptoms. In two of these cases there was a vague feeling of abdominal distress, after hearty meals, but otherwise nothing to draw attention to the stomach. In all three achylia was present, enzymes absent, rennet zymogen present in 1–160 dilution.

Case IX.—This case gave neither gastric nor intestinal symptoms, but from time to time there were attacks of intestinal spasm resembling pseudo-angina, apparently of toxemic origin. The patient was a well-nourished, healthy-minded lady, thirty-two years old, free from every trace of nervousness. For years there had been muscular pains of a shooting character from time to time, but further than this a rheumatic history could not be obtained. For the past five years there occurred with, or without exertion, attacks of paleness, faintness and moderate dyspnœa. Other vaso-motor symptoms, such as sudden flushings, were also noted. The heart and arteries were normal. In the urine neither albumen nor sugar could be found, but there was an excessive amount of indican. The fasting stomach contained a small amount of mucus; the test-breakfast was undigested, mixed with stringy mucus, and contained neither free nor combined HCl.; enzymes were also absent, rennet zymogen was active in 1–120 dilution.

Case X.—The next case of this series was a female, thirty-five years old, who six years ago was attacked by vomiting and purging, lasting pretty continuously for four months. Since then the attacks have occurred about every year with diminishing severity, so that the last attack lasted only four days. Three years ago she was suddenly seized with severe pains, running from the right free border of the ribs, to the back and downward, lasting a few hours and not being followed by jaundice. The following year jaundice occurred for a few days without pain; no other history obtainable. Between the attacks of vomiting patient feels perfectly well and strong, and has no complaints whatever. Repeated examinations, extending over eighteen months, have shown complete absence of enzymes. Rennet zymogen has been active up to 1–64 dilution, delayed up to 1–160, inactive in dilutions weaker than this. Under achylia diet and Kissingen there have been no attacks of vomiting during this period.

Upon comparing the hyperacid cases without atony with the similar group of the anacid class, a great similarity is noted in two clinical forms.

Only three of the ten hyperacid group complained of intestinal symptoms of diarrhœa and emaciation. Three of the eleven anacid cases gave exactly these symptoms. Take for example Case 1 of the hyperacid cases, giving intestinal symptoms: male, forty-five years old, who for three months had suffered from diarrhœa and emaciation, and compare Case 2 of the anacid group, giving intestinal symptoms: a male, forty-three years old, who for three months had complained of diarrhœa and emaciation. Here were two cases giving exactly similar symptoms. One had hyperacidity, the other had anacidity. Neither gave gastric symptoms, both had normal colons. One was cured by reducing the hyperacidity by soda, and the other was cured by increasing the acidity by Kissingen water.

Secondly—In both sets of cases, the hyperacid and the anacid, there is a group of cases complaining of biliousness—two of the ten hyperacid cases and two of the eleven anacid cases. Neihter group gave gastric symptoms. It is interesting that two gastric conditions, apparently so diametrically different from each other, should give the same clinical course.

Anacidity with Atony, 8 Cases.—Two cases gave entirely intestinal symptoms.

Case I.—Female, fifty-one years old, two years ago was suddenly seized with sharp attack of diarrhœa lasting several weeks. Since then the trouble has returned from time to time, and during this time the patient has lost thirty pounds in weight. There are no gastric symptoms. Examination shows an atonic and displaced stomach, the greater curvature lying 10 cm. below the navel. The fasting stomach contains a small amount of mucus. Test-breakfasts repeatedly taken during the past year have shown a total absence of free and combined acid, enzyme absent, rennet zymogen active in 1-160 dilution. The colon was moderately displaced, there was neither atony nor catarrh, the stools were free of mucus and their microscopic examination was normal. Under treatment by Kissingen water and a suitable anacid diet the diarrhœa has not returned during the past year.

Case II.—This case presents, in a striking way, a number of most important, and to the mind of the writer entirely new, points in the treatment and course of anacid gastritis. Male, forty-five years old. Well until September, 1899, when, after eating clam chowder, diarrhœa developed, lasting several days, and then subsided. In October a similar attack occurred without apparent cause, lasting a week. During November and December the bowels continued irregularly loose. Acute exacerbations of increasing severity in January and February, 1900, From this time till he entered Trinity Hospital in December 28, 1901, he suffered from chronic diarrhœas, having 10 to 12 stools daily most of the time, varied by intermissions of less severity. When seen December 28, 1900, nutrition was poor, the weight was 105, a loss of forty pounds during the year. There was an appearance of cancerous cachexia; hæmoglobin, 54. Abdomen was distended with gas, no masses, no tenderness. Colon irrigation showed normally located colon, of normal muscular power and absence of catarrh. Dejecta resemble small-intestinal stools, without mucus or blood, 10 to 15 daily. Stomach showed atony of its wall by the ordinary tests. Six hours after breakfast food remains are present in the stomach. Test-breakfasts show complete achylia, with a large amount of mucus. Lavage was ordered and given daily by a trained nurse, for two weeks, without the least change in the patient's condition, although he was given at the same time a diet suitable for his achylia. The lavage water returned perfectly clear, although it was noticed that all the water was not returned, thirty to thirty-six ounces remaining in the stomach. A suction lavage apparatus was improvised, which brought away the residual water and a great amount of mucus. At the same time daily applications of intragastric faradism were given. The result was that the tone of the stomach improved to such an extent that the residual water was decreased so that only three to six ounces remained in the stomach after lavage, the acid, returned in normal quantity, diarrhœa ceased and for a year has not returned, the blood count rose to 85 and in six weeks the patient increased in weight from 105 to 145 pounds. For the past year the patient has been in perfect health, working as foreman in a stone quarry.

Two cases gave intestinal symptoms, in combination with those of gastric atony and general neurasthenia.

Case III.—Female, thirty years old. For thirteen years had been complaining of intestinal indigestion, for the past five years the symptoms have been so severe that the patient was obliged to lead the life of a semi-invalid. The chief complaint was of alternating attacks of diarrhœa and constipation. These diarrhœal attacks lasted only a day or so at a time, but were accompanied by such dizziness, faintness, and prostration that it would require a week or ten days of careful nursing to restore the patient to her former strength. By the time this was accomplished another diarrhœal attack would occur. The atonic symptoms consisted of the constant pressure of gas in the stomach and intestines, and a dull, aching pain in the epigastrium, induced rather by the quantity than the quality of food. The patient was neurasthenic, poorly nourished, and complained of a steady feeling of nausea, which, however, was never followed by vomiting. This feeling of nausea was regularly induced by fatigue or mental excitement. Examination showed an atonic stomach, with the greater curvature lying a finger's breadth below the navel. The fasting stomach contained a large amount of glairy mucus. Test-breakfast gave evidences of a catarrhal gastritis, with total acidity of 18, with no free HCl.; combined HCl., 10. The colon was normal in all of its functions and not catarrhal, the stools were apparently normal. Under a treatment, chiefly of Kissingen water and intragastric faradism, the symptoms rapidly diminished, and the patient has remained in comparatively good health for over a year.

Case IV.—Female, fifty-five years old. A nervous, gouty, complaining lady, "with pains in every part of her body all her life." suffered with morning diarrhœa and cramps for one year. There were constant gaseous accumulations in both stomach and bowels, the symptoms of hyperacidity, such as heartburn, were occasionally present, although test-breakfasts showed an entire absence of organic or inorganic acids, either free or in combination; enzymes were absent; rennet zymogen active in 1-200 dilution. Colon irrigations were normal. Marked insomnia was present.

Two cases gave chief symptoms, waves of nausea, independent of food. Both were neurasthenic:

Case V.—Female, forty-eight years old. For about ten years there had been more or less constant a feeling of fulness, and distention in the central abdominal region, worse about two hours after eating. There were waves of nausea, sometimes transitory, at other times extending over days, not intensified by eating and not interfering with a fair appetite. The patient has been under a severe and continual nervous strain for years, and the symptoms are regularly intensified by an increase in the amount of nervous worry. Examination shows the stomach lying from 4cm. above to 7cm. below the navel, and in an atonic condition. Lavage leaves ½ liter residual water, which the stomach is unable to express. The fasting stomach contains a small amount of neutral mucus. Test-breakfasts show absence of HCl., total acidity of 10-12. Enzymes absent, rennet zymogen weak in 1-200 dilution, active in 1-100 dilution

Case VI.—Male, forty-five years old. During youth the patient had suffered from dyspepsia and severe heartburn. Those symptoms continued for a few few years and then subsided, to reappear in increasing intervals and with diminished severity. Ten years ago acute septicæmia developed, from an operation cut, and ran a long and severe course. During convalescence the appetite was lost, and there was regurgitation of food having a rotten-egg flavor, together with continual nausea. Since then the stomach has been washed almost daily, the morning lavage bringing a large amount of mucus, usually without food remains. If, however, the patient has been overtired, or has partaken the previous evening of a heavy dinner with wine, food remains would be found in the morning fasting state. The rotten-egg odor has not been noticed for some years. There is considerable gas, both in stomach and in bowels, and a sense of heaviness in the stomach after meals, depending both on quantity and quantity of food. The most distressing symptom was nausea, more or less constant, not influenced by food but increased by mental fatigue. Dull headache and other signs of a neurasthenic constitution were present. Examination showed a prolapsed stomach in vertical position but with atonic walls. Fasting examination revealed the presence of a considerable amount of neutral mucus without food remains. Test-breakfast was perfectly undigested with a total acidity of twelve, no free or combined acid; enzymes absent, rennet zymogen positive in 1:80 dilution, weak in 1:160.

One case bore the symptoms of hyperacidity:

Case VII.—Male, forty-five years old. About an hour after eating the patient complained of heartburn and moderate feeling of gaseous distention, these are the only symptoms present. Examination showed achylia even at the time of "heartburn." A course of Kissingen was advised, and in four weeks the acid had returned, the total acidity of test-breakfast being twelve. Coincident with this was the total disappearance of the hyperacidity symptoms. The peculiar feelings in the case, and also noted in Case IV of this series, were probably due to the excessive dryness of the stomach contents so characteristically observed in the test meals of achylia patients.

Case VIII.—This case gave no gastric symptoms whatever, but complained of nervous depression and occasional dizzy attacks. Examination showed an atonic stomach, with anacid mucous gastritis; total acidity of test-breakfast 18, no free HCl, combined HCl 12, stomach not completely emptied six hours after light breakfast. Lavage brings large quantities of mucus, but leaves ½ to ⅔ liter residual water that the stomach cannot expel.

Conclusions.—1. In uncomplicated chronic gastritis not of alcoholic origin, if the muscular power of the stomach be good, the only symptom apt to be referred to the stomach is acidity. This occurs in about half of the hyperacid cases, but may be observed in the cases of complete achylia. Cases with normal acidity, and the vast majority of cases of anacidity, give no gastric symptoms.

2. The hyperacidity cases may give a course resembling that of a neurosis in that the symptoms are intermittent and are easily influenced by nervous conditions. It would seem, however, that a long-continued gastric neurosis was exceedingly rare, and that the great majority of such neuroses were rarely the neurotic outbreak of an organic lesion.

3. In gastritis, contrary to the accepted teachings, the following negative facts are to be noted: (a) The appetite is good. The few exceptions are observed in advanced atony, where the quantity of food is not well borne, and in cases of neurasthenia. In neither case, however, is the gastritis itself the cause of the anorexia. (b) Pain occurs in two ways: (1) From acidity, differing in no way from similar pain in cases of nervous hyperacidity; (2) From gas. This latter pain differs in no way from that observed in cases of simple atony without gastritis, so that pain does not seem to be a symptom of gastritis proper. (c) Nausea does not occur in relation to meals. Patients with atony, and those who are neurasthenic, may complain of nausea, but the nausea is not related to meals, and does not interfere with a normal appetite. It usually occurs when the patient is tired or nervous. (d) Vomiting does not occur in the non-alcoholic cases. (e) Unless there be diarrhœa the nutrition is good, and as a rule, the patients are not anæmic. Exceptions may be made in cases of atony, but in these cases the anæmia may well be the primary condition.

4. If the muscular power be poor, gas is present as a prominent symptom. This is more apt to occur in hyperacid cases, and is probably due to swallowed air. As this same symptom is observed in a similar number of cases of simple atony, the symptom is not directly due to the gastritis.

5. Gastritis may give rise to severe and long-continued diarrhœa and emaciation, which may be mistaken for colitis or malignant disease of the colon. The diagnosis, however, should present no difficulty if a careful examination be made. These cases are more common than is usually supposed, and occur both in the hyperacid and in the anacid cases. Between the two a diagnosis is possible only by gastric analysis.

6. Biliousness and its allied symptom-complexes are rarely, if ever, due to a primary functional disturbance of the liver, but are almost regularly due to an intestinal toxæmia traceable to some derangement of gastric chemistry, whereby improperly prepared chyme enters the intestine.

7. Anæmia and constipation are the chief and only symptoms in a great many cases of even well-marked gastritis, and their continuance without apparent cause should justify an analysis of the gastric contents.

Clinical Department.

POST-OPERATIVE OBSTRUCTION IN A CASE OF SARCOMA OF THE UTERUS AND MESENTERIC CYST DUE TO INCARCERATION OF THE SMALL INTESTINE IN A HOLE IN THE MESENTERY.

By CHARLES S. HAMILTON, M.D.,
COLUMBUS, O.

Mrs. P., aged forty-four years, white, mother of two children, consulted me on account of menorrhagia of moderate degree. It had existed for a few months past and had not as yet caused much impairment of health. She was able to do her own work. Patient had always felt a "weak spot" in the right ovarian region. She was conscious also of a swelling in the lower abdomen.

She was a slender and rather delicate-looking woman, whose mother and father are supposed to have died from tuberculosis. Her examination was negative, except in so far as the pelvic organs were concerned. The uterus was found retroverted and the body symmetrically enlarged. Its size was such as to indicate strongly the presence of a growth rather than a metritis. To the right of the uterus, occupying a location partly in the pelvic and partly in the inguinal region, was a tense, painless, fluctuating tumor, not very intimately associated with the uterus and of the size of a child's head. A diagnosis was made of a retroverted uterus containing a fibroid in the fundus, with an ovarian cyst of the right side, and an operation was advised.

A few weeks later she entered the Protestant Hospital, and preparatory treatment of the usual character was at once directed. Two days before the time set for operation she was taken with persistent vomiting, accompanied with very little, if any, pain in the abdomen. At the end of eighteen hours the vomiting ceased. I had been unable to account for it, there being no evident cause. She had never suffered from a similar attack before.

The operation occurred under ether anæsthesia on January 8, 1900. Ater opening the abdomen the field was thoroughly shut off from the general cavity by packing with wet towels. The cyst was found to be mesentric. It presented on the interior surface of the mesentery of the ileum within about eight inches of the ileo-cæcal valve. Its relation to the intestine was such as to leave the caliber of the gut entirely free. The cyst was readily enucleated without damage to any large branch of the mesentric vessels, and its bed was entirely covered by stitching the peritoneum of the mesentery over it. The uterus was thne brought into view and the diagnosis confirmed (apparently). Hystercetomy, according to the method of Kelly, was done. The patient bore the operation well and was put to bed in good condition. Two days after the operation the patient's bowels moved readily in response to calomel, followed by a saline. From this time up to about the ninth day the convalescence was not marked by any symptoms out of the ordinary. On the ninth day, however, it was observed that there was slight distension, with occasional cramy-like pains in the abdomen and inclination to vomit. The administration of a physic was not followed by a stool as promptly as one would have expected, nor did the distension subside completely after the stool. By the thirteenth day the clinical picture resembled an incomplete obstruction with rather mild symptoms. In the afternoon of this day I was hurriedly called, because of violent abdominal pain with threatened collapse. I found her almost pulseless, with cold extremities and moderate tympany. Vaginal examination showed a coil of small intestine lying in the culdesac, distended out of all proportion to the degree of general distension that existed. On the ground of a possible adhesion betweenthe intestine and the stump of the uterus, I opened the culdesac and encountered only moderate adhesions, none of them, to my mind, accounting for the obstructive symptoms. Nevertheless the patient seemed to derive some benefit from the manipulations, for after recovery from the shock, which, on account of her weakened condition, was extreme, the bowels acted, though not very thoroughly. On the 14th and 15th days she became still more distended, vomiting was frequent, finally no gas or fæces passed, and there became evident in the right inguinal region a much distended coil, which could be felt through the abdominal wall, and was evidently very near to the region of the obstruction. As by this time (16th day) she was too weak to stand any prolonged operative procedure, an incision was made under local anesthesia and enterotomy performed, without search for the nature and location of the obstruction. The small intestine was opened some distance above the ileo-cæcal valve. Immediately following the enterotomy there was a profuse fecal discharge, but, unfortunately, without any special benefit to the patient. Her strength failed rapidly, and death ensued within eighteen hours.

Report of Necropsy and Microscopic Examination of Specimens by Dr. J. M. Phillips.—The body was somewhat emaciated; rigidity moderately marked; abdomen much distended. The laparotomy wound well united, except near its upper part, where there was a granulating sinus, resulting from a stitch abscess. The artificial anus patulous, a quantity of fecal matter, staining the pad, covering it. On opening the abdomen the omentum was found covering the intestine, but tightly adherent to the under surface of the laparotomy wound. The coils of small intestine were greatly distended, the large intestine collapsed and almost empty. There was no evidence of general peritonitis, but the serous surfaces were moist. The thoracic cavity when opened presented an almost normal appearance, except for numerous minute petechiae. The pericardium contained a little more clear fluid than normal. There were no gross pathological changes in the heart. On the outer and lower surface of the left lung the visceral and parietal layers of pleura were tightly bound together by adhesions resulting from a former pleurisy. The spleen was normal in size and appearance. The liver slightly enlarged, a few petechiae on its surface and a well-marked atrophic depression, "corset atrophy," on its right lobe corresponding to the edge of the ribs. The stomach was greatly distended, extending almost to the umbilicus. The seat of obstruction was found about 18 inches above the cæcum, where a loop of intestine, about three inches in length, had slipped through the mesentery some months before, inasmuch as it was bound to the surrounding intestine by some very firm adhesions, those on the apex being especially firm. This loop was collapsed and somewhat inflamed. Just beneath it a new knuckle of gut had pushed through the same opening in the mesentery and become strangulated. This consisted of that part of the small intestine immediately above and continuous with the gut which formed the old hernia. Above this point the small intestine was greatly distended, while the strangulated knuckle was inflamed, friable and almost gangrenous, with some new, easily separated adhesions surrounding it. The opening in the mesentery had thick rounded edges, and had evidently existed for a long time or was congenital. The entire mesentery was abnormally long. A short distance above the obstruction an enterostomy had been performed. There was only the usual amount of inflammation about the seat of operation.

About eight inches from the ileo-cæcal valve the rent in the mesentery, formed by the removal of the cyst, was found. It was nicely closed.

Cyst.—The mesenteric cyst is about 14 c.m. in diameter, and contained a fluid of the color of thin milk. Histologically. the wall consists of fibrous tissue, covered on both internal and external surfaces with endothelial cells. The wall shows marked calcareous infiltration in places.

Uterus.—The entire uterus is hypertrophied, the walls being about 2 c.m. in thickness. When opened a large sub-mucous tumor, about 9 c.m. wide and 11 c.m. long, is found, springing, for the greater part, from the anterior wall of the uterine cavity. When fresh the tumor was nodular, rather softer than the usual uterine fibroid, pale pink in color and quite vascular in some areas. In places a fairly well developed capsule can be demonstrated, in other portions the tumor is intimately connected with the surrounding uterine tissues.

Histologically, it consists of more or less elongated fibers, running in various directions. In the vascular areas of the tumor the vessels were of two kinds—large vessels, surrounded by thick fibrous walls, and small vessels with very thin walls. Around these vessels there are epithelioid cells, some of which are irregular in shape, but the greater number are oval. Portions of the avascular areas are composed of ordinary fibrous tissue, but they are, for the most part, made up of cells which are distinctly longer than those around the bloodvessels. However, the shorter cells are occasionally found here also. After staining with Van Giesen's stain, none of the fibrillated portion takes the picric acid.

Scattered, irregularly, throughout the tumor, occurring in rows or singly, and in some places in great numbers, are mast-cells of Ehrlich. The tumor is fibro-sarcoma.

Dr. Simon Flexner has kindly examined the tumor and confirmed the diagnosis.

It should be noted that the mesentriccyst was situated 8 degrees from the ileo-cæcal junction, while the mesenteric opening through which the intestine had slipped was only 10 degrees higher up. It would seem as though the latter should have been detected. I ascribe the fortune [illegible] to the thorough packing with moist towels by which everything which was not directly in the operative field was excluded from it. In any event the occurrence is most interesting in the light of a recent paper by Howard Kelly, generally advocating systematic exploration of the abdomen at the conclusion of operations dealing primarily with pelvic disease.

The autopsy reveals the fact that a loop of small intestine had been in the mesenteric opening but not strangulated for an indefinite period. This may be inferred from the age and density of the adhesions holding it in place. There is nothing in the history of the case which suggests that the conditions produced symptoms previous to the attack of vomiting from which she suffered two days before the operation, which I had been unable to explain. This may have been associated with the adhesion in question. When the attack of pain occurred on the 9th day after operation the additional coil of bowel doubtless slipped through the hole in the mesentery and then the serious symptoms began. At no time was the consequent obstruction complete, and the symptoms accompanying it were vague and atypical until nearly the end. A rapidly performed abdominal section, at an early period, would have revealed the nature of the disturbance and probably also have permitted its successful treatment.

REPORT OF A CASE OF TUBAL PREGNANCY DIAGNOSED ONE WEEK PREVIOUS TO RUPTURE, VERIFIED BY OPERATION FOLLOWING RUPTURE; RECOVERY—PRESENTATION OF RARE SPECIMEN.*

By EDWARD N. LIELL, M.D.,
JACKSONVILLE, FLA.,
FORMERLY LECTURER ON GYNECOLOGY, NEW YORK POLYCLINIC.

Mrs. X, on February 10 last gave a history of having missed two menstrual periods, the last one due January 23. Upon examination the uterus was found but slightly enlarged, but the left tube was found enlarged to the size of an orange. A diagnosis of probable tubal pregnancy was made and the patient so informed, though it was difficult to make the patient understand and realize the nature of such a condition. I requested her to call upon me again immediately following the time of expected next period.

February 17 I was called in haste, and found her rallying from an attack of syncope, and in great pain. She stated she had been taken suddenly with an acute and excruciating pain in the left ovarian region, and fainted away. An examination verified the diagnosis made one week previously, with the addition of rupture and hemorrhage. An immediate operation was advised, but the patient strongly opposed it.

Knowing that peritonitis would at least have to be contended with until I could, perhaps, induce her to be operated upon I at once placed her under treatment.

On March 11 the tenderness had subsided sufficiently to enable me to map out an adherent mass, the size of a small grape fruit, posterior and to the left of the uterine; the uterus, as before, was but slightly enlarged and not tender. This time, upon laying the exact condition before her, of ruptured tubal pregnancy with complicating hæmatocele, and again strongly advising operation she consented. The operation was being performed on March 17 just one month following time of rupture.

Upon opening the abdomen I found the enlarged tube, a slightly cystic ovary, and a mass of dark, clotted blood and fresh lymph filling the pelvic space completely behind and to the sides, especially the left of the uterus. The artificial fixed position of the uterus as a result of a ventral fixation performed at the German Hospital, New York, three years previously, admitted of a diagnosis more readily than otherwise would have been the case. The adhesions were readily broken up and the mass of clotted blood was removed. When the parts had been drawn into the abdominal opening it was seen that the pregnancy and distention occurred in the distal portion of the tube near the fimbriated extremity, the tube being an unusually long one. Convalescence was rapid. The abdominal sutures of Chinese twisted silk were removed on the tenth day, when it was seen that primary union had taken place throughout. The patient had been delivered of two children at full term, some years previously.

*Read at the recent meeting of the Florida Medical Association.

Heart Strain; Its Result and Treatment.—J. M. G. Carter says that the effect of heart strain is seen in two ways: (1) By overwhelming disturbance causing immediate faintness, possibly paralysis and death. (2) A more gradual dilatation from lighter and daily strain. The heart muscles are in the condition of muscles in any other part of the body where the limbs become unduly stretched and strained, the rhythmic action becomes feeble, tremulous and imperfect. Prophylactic treatment in civil life would require elimination of corsets and [illegible] dress, a quiet well-regulated life, avoiding all over-exertion. In military life it requires such an adjustment of accoutrements and exercises as will prevent overwhelming the heart in its efforts to carry on the circulation. The proper advice to such persons is to leave the service. Hygiene and diet must be carefully regulated, all gas-producing foods being avoided. In asthenia digitalis and strychnia are the most important remedies; the addition of tonics will restore the tone of the heart and reduce its [illegible] activity.—*Illinois Medical Journal.*

The Practical Bearing of the Study of Immunity.—J. W. Washbourn asks the question whether the remarkable discoveries made in the line of bacteriology are likely to lead to therapeutic advances, and answers it in the affirmative. It has been found that the infection of a serum containing a lysin leads to the formation of an anti-lysin, a substance capable of destroying the lysin. Is it not possible that we may be able to obtain a serum capable of annulling the effects of the hypothetical lysin which is the cause of the destruction of the kidney cells in chronic nephritis? And is it not possible that other forms of so-called parenchymatous inflammation may come within the reach of treatment within these lines? Moreover not only the infection of living cells, but also the infection of chemical products, leads to the formation of anti-bodies in the blood. That the study of immunity will continue to advance our knowledge of the treatment and causation of disease is sufficiently certain.—*Treatment.*

The Use of Gelatin as a Hæmostatic.—Y. Miwa asserts that the celebrated San-Han-Ron, a medical treatise written by the Chinese physician Chan Chiyun Kyon about 204 A.D., contains a description of the hæmostatic properties of gelatin in all forms of hemorrhage, and he adds that many references to this fact are to be found in Japanese writings of a somewhat later date. The usual form of application was in solution, though insufflations of the dry powder were recommended in epistaxis. In internal hemorrhage the remedy was usually combined with vegetable astringents, and tonic and blood-forming powers similar to those of iron were also ascribed to it.—*Centralblatt für Chirurgie.*

New York, May 31, 1902.

ERRORS IN THE CHRONOMETRY OF LIFE.

ALL that the late Sir James Paget spoke or wrote is deserving of close attention, not only for the wide range of knowledge therein displayed, but also for the clear and accurate manner that he possessed of presenting any subject, however technical, to his audience, so that it should be easily understood.

Some of his published orations are masterpieces, and no less excellent are a number of selected essays and addresses recently issued.

By no means the least instructive of these is the one mentioned above.

Sir James Paget pointed out—a fact too apt to be forgotten—that there is a chronometry in life, as well as a chemistry or a mechanics, and that, in the study of pathology, we do not sufficiently consider how much of disease or of its variations may be due to disturbance of the time-rate at which the organic processes should be discharged.

The inquiry is also suggested, into the influence of the variability of a time-rate, as one of the conditions upon which may have depended the "selection of species," and the author of the essay goes on to say, "It is not difficult to imagine many terrestrial events in which the 'survival of the fittest,' among species or individuals might depend, chiefly, on the possibility of adjustment of a time-rate in one or more processes. In the ordinary course of nature the time-rates in each creature are adjusted to those of the external conditions most necessary to its life. The development and hatching of the young pigeon keep time with the development of its parent's crop; the development of the mammalian fœtus with that of the mother's mammary glands. Such adapted changes in parents for the sake of their offspring are everywhere to be seen, and so are the instances in which the development of animals of all kinds keep time with those of the plants or other animals on which they live."

It is hardly too much to say that the whole course of nature among living things thus depends on their mutual adjustment in time as well as in all the other conditions of their lives. And if this be so, then any alteration of the time-rate of life in any species might gravely affect its fitness for an unchanging environment, or might lead to the natural selection of a few of the species whose differences from the rest would be transmitted to some of their offspring.

The errors of chronometry or unpunctualities in life are then dealt with at some length, a part of which only can be referred to within the scope of an article.

It is shown that those young persons who develop most rapidly, and present the appearance of being older than their age, are usually healthy and potent in resistance of disease, while a large majority of those who, when young, look less than their age, are weakly, some scrofulous, some syphilitic by inheritance, or rickety; and many more—though not plainly thus diseased—are certainly prone to scrofula, tuberculosis, acute rheumatism, and other diseases of this class.

As to the conditions which have retarded the time-rate of development in the young, the essayist was of the opinion that the health, good or bad, of parents, has small influence on the time-rate of children in early life, and that the children of the old are different in this respect from those of the younger.

The most frequent cause of delayed growth, when any cause for it can be assigned, is an acute illness, such as scarlet fever, diphtheria, or whooping cough.

Children's heads and nails are considerably checked in growth after each of their occasional illnesses, while the seemingly rapid growth which often occurs in the young after an especially acute attack of sickness is seldom, if ever, associated with equivalent growth and development of organs, whose size is more important than is the length of the lower limbs and spine. Nor, again, is that strange increase in fatness, which is often observed in the young after serious sickness, significant of high development.

A slow time-rate is frequently found in those children who were prematurely born, and the delays which happen to some in later years, are due to slowness in the degenerative processes of life; and we may fairly guess that this may also explain the many instances of great longevity in persons who, when they are very old, say that they were never strong, never vigorous in their life, exemplifying the homely old saying that a creaking gate generally hangs the longest.

Premature development of parts is also touched upon, and it is shown that this kind of development is only too commonly seen in the teeth. Their time-rate may be faster than that of the jaws, with which they ought to coincide exactly, and in this case they come out crowded, and the more so the more exactly they keep time with one another. Often, however, they do not keep time either with one another or with the jaws; they come out both crowded and disorderly.

The explanation given of prematurely gray hairs is that these are simply a degeneration of the parts, and that analogous untimely degenerations may occur without disease in much more important parts. All parts do not often grow old at the same rate, and as people of the same age, according to the register, are, in many instances, of widely different ages by every other test, so it is with the several organs of the same body. Some may have grown old at a much more rapid rate than have others, and this, not because they have been the seats of any morbid process; their errors may have been merely chronometric; they have not kept time; they have too quickly become gray.

There is much reason in the argument that many cases of failure in health are due to these errors in the chronometry of life, and Sir James Paget concludes by expressing the opinion that our pathology, and sometimes our practice, would be improved if local defects of working power were more often thought of as errors in the time-rate of life in the degenerative process. If we could thus think of the age of each part as not always wholly or equally expressed by the time that has elapsed since it was first formed, if we would bear in mind that any internal organ may deviate from the general time-rate of the body as much as the teeth, the hair, and the skin, which we so commonly think of as old before their time. We should not be content with asking a patient how old he is, we should ask ourselves how old is his heart, or his brain, or any other part which seems more or less healthy than the rest.

THE NEW LYING-IN HOSPITAL AND ITS APPEAL.

The recent action of the general board of managers of the New York Society of the Lying-in Hospital in issuing an appeal to the public for additional funds with which to defray the contemplated expenses of the coming year causes no little surprise among professional and lay circles, for at the opening of the hospital some three months ago no apprehension was expressed on meagerness of income. The donator, Mr. J. Pierpont Morgan, after bestowing upon the society a gift having an approximate valuation of $1,500,000, considered that he had discharged in full all the voluntary obligations assumed by him in erecting and furnishing the hospital, and that the public or those otherwise interested in the welfare of the society and prosecution of its work should exert the strenuous efforts necessary to secure sufficient capital for a permanent endowment which would suffice in the future to adequately cover the entailed expenditure of maintenance. The public is apprised through the appeal that the society is in receipt of an income which cannot provide for more than sixty-two beds, or one floor out of the eight comprising the building, and including the municipal allowance of $12,000, the combined income from all interest-bearing investments, with general contributions, does not exceed in the aggregate $30,000. This sum represents but one third of the estimated cost of operating only one half of the hospital, and leaves a deficiency of $60,000 to be accounted for at the end of the fiscal year.

The running of the hospital to its full complement has been apparently abandoned as impossible, even under the most favorable conditions. Accepting these statements under advisement, it is evident that the society is in possession of a magnificently equipped plant with a disproportionate working capital, at the same time is somewhat embarrassed by an unavailable permanent endowment fund. Prior to entering upon the construction of the new hospital, the society must have been cognizant of the limitation of its treasury to handle the greatly increased scope of work, and now, on completion and in partial operation, the subject of future provision may prove a problem of difficult solution unless those associated with the society are successful in soliciting the requisite amount of money.

It cannot fail to suggest a wantonness of commercial acumen and lack of judgment to assume so large a burden merely on a hopeful and speculative outlook. It may be a fashion, though a deplorable one, for municipalities to enter into extravagant undertakings with the hope that a funded and funded debt will offset imposed obligations, but for a private association to boldly shoulder prospective liabilities in the maintenance of a hospital, the municipal need of which has never been evidenced by the overcrowding of similar institutions, fails to invite hearty co-operative sympathy.

The completeness of hospital accommodations in New York city for worthy indigent maternal cases is too well known to require other than passing reference in these columns, and it is safe to say that the erection and support of the Morgan Hospital in its immediate neighborhood not only invites but creates a continuance of dispensary and hospital abuse. Many of those applicants seeking admission can comfortably provide for themselves in their own homes, thus the hospital in accepting such cases deprives the physician in the district of a fee to which he is justly entitled. In the absence of the hospital these cases would seek and pay for medical attendance. The fee, even though small, partially compensates the physician for services rendered and serves as a stimulating encouragement to continue his practice with doubled effort. This refers particularly to the younger physicians, who within the past five years have settled on the East Side and, after their long period of patient waiting and outlay of money in preserving a residence in a promising locality containing homes of successful wage earners, are now to compete with this formidable free plant.

Moreover, it has been noted by doctors living within the environs of maternity hospitals that former patients who were well able to pay (and pay promptly) neglect to call them to attend the next accouchement, and on subsequent inquiry learn that the case was confined at a maternity hospital which, in readiness to serve the purpose of its erection, receives applicants after a necessarily brief examination into the true worthiness of the case.

It is unquestionably admitted that a difficult problem confronts hospital authorities in discriminating between the pseudo and genuine need of an applicant, but laxity of inquiry and desire of the institution to have a large service are in a measure responsible for the continuance of hospital abuse. Certainly it is very harsh for the young physician to be forced to realize that a hospital or dispensary in a residence district composed of good wage-earners, unjustly deprives him of professional reward by dispensing medical attendance to unqualified applicants, and, incidentally, creates pauperism by giving much for little or no return. Such a condition as this is not charity, but an educational method of instructing people of moderate, though sufficient, means for substinence to neglect all provision for sickness and to disregard their individual duty to society at large by relying, in emergency, upon the gratuitous dispensation of aid.

Now that the hospital exists, and funds for its support are needed, it is to be hoped that these will shortly be forthcoming, and that the work of relieving those needy cases who present themselves as applicants for admission may in no way be hampered. Yet it would seem eminently fit that the local physician's interest be a constant subject of consideration by the hospital authorities, so that neither the practitioner nor the worthy mother be discriminated against in the gratuitous dispensing of medical attendance.

SUITS AGAINST HOSPITAL PATIENTS.

The outcome of recent suits brought by Dr. George R. Fowler of Brooklyn against so-called hospital charity patients for professional services rendered, will be watched with a great deal of interest by every medical man who has been defrauded under like circumstances. It is so well known that the physician or surgeon, wherever he may be, is always ready to attend the poor gratis, and that every advantage is taken of his charitable impulses. There is hardly a hospital to be found in which the abuse of charity by patients able to pay for services does not exist, and the physician or surgeon on duty is particularly liable to the imposition. While in most cases the patient is the principal party to the fraud, the hospital itself is seldom backward in condoning the offence, especially when board is paid and private rooms hired. It need not be said in this connection that the semi-private hospitals are as a rule run more on the hotel principle than that of a broad and helpful charity. The man who can fill the greater number of private rooms is the one chosen on the staff. This being the case, there is a natural premium on the board and room question. The unvarnished truth is that the physician or surgeon at a modern American hospital is required to proffer his services for little or nothing, or rather he is expected to fall in with the views of the hospital authorities, in a manner of speaking to efface himself, and to permit his conduct to be guided by what the management considers to be the best interests of the institution to which he is attached.

Patients who can well afford to pay, but who are so mean as to grudge the medical man his just dues, for restoring or endeavoring to restore them to health use the hospital as an easy and convenient means to obtain treatment for nothing, and, as remarked before, so long as the hospital profits, its management is not too eager to look after the interests of the doctor. The hospital authorities as a rule make no effort to discover the status of a patient, but if he comes with money in hand, he is welcome to the best advice and treatment, and the unfortunate medical man too often must grin and bear it.

If a member of the medical staff is sufficiently bold to question the right of the hospital management to dictate his conduct and to stand up for his just claims, he is requested to resign, or, in plain English, he is politely ousted, and a more pliable individual is put in his place.

The original intention of the founders of hospitals was that they should be charitable institutions, conducted solely for the benefit of the poor, and it would assuredly make these worthy men rise from their graves if they could see the manner in which their projects have been frustrated and could witness the grasping commercial principles upon which the hospital of to-day is run.

There is no objection to paying wards in hospitals, in fact, under the circumstances these are necessary, but it is distinctly wrong that an institution of this nature should be utilized by unscrupulous, conscienceless persons to cheat the medical man.

The result of this fraudulent imposition upon the medical profession will be—indeed all signs point that way now—the multiplication of private hospitals as a matter of self-defence.

That Dr. Fowler will win his suit will be the heartfelt wish of every medical man in the country. It is a test case, he is fighting the battle of the profession, and if he is successful, a curb will be placed on such patients as should pay for medical services, but who, through the so-called charitable institutions, defraud the medical man at every turn.

Bacteria in Milk.

There was a time, not far distant, when nothing was known with regard to bacteria in milk. If the supply were fresh, not visibly dirty, and sufficiently plentiful to meet the needs of the population of civilized countries, the majority of the people considered that no more could be expected. At the present time, however, this view of the case no longer prevails. It is allowed on all hands that bacteria abound in milk, and the only ground for disagreement is as to the extent these cause injury to health.

The general public is prone to imagine that all bacteria are disease-bearing, and that the greater number of these a certain milk contains, so much the more dangerous to health must this milk be.

Dr. Veranus A. Moore of Cornell University has written under the auspices of the State of New York, Department of Agriculture, a pamphlet explaining clearly the true nature of the situation.

After pointing out that all bacteria are not harmful, the writer says that the problems arising from a knowledge of bacteria in milk that have already been studied, but which need to be more thoroughly investigated, resolve themselves, very naturally, into three groups, namely:

1. Those which pertain to the manner in which bacteria gain access to the milk.
2. The effects bacteria produce (*a*) on the milk itself, and (*b*) the effect of the changed milk upon the consumer.
3. The methods of handling milk in order to keep the number of bacteria and the products of their growth at a possible minimum point.

As to the manner in which bacteria gain access to the milk, Dr. Moore remarks that the inquiries into the ways and means by which these microorganisms could gain entrance to the milk show that, for the greater part, these external sources consist:

1. Of particles of dirt, laden with bacteria, which fall into the milk utensils before and after the milking process.
2. The dirt and filth which fall into the milk pail, from the skin of the udder and groin of the cow at the time of milking.
3. The dirt otherwise introduced from the hands and clothing of the milker.
4. The bacteria that remain in the utensil from improper cleaning.

There is yet another source from which bacteria can gain entrance to milk, and that is from the milk ducts of the udder itself. Various investigators have experimented in the matter with the result that the bacteria emanating from this source have been identified on many occasions.

With regard to the significance of bacteria in milk, as Dr. Moore aptly says, nearly if not all of the changes that occur in milk subsequent to its escape from the udder are primarily caused by bacteria.

Therefore the object of dairy farmers, and, indeed, of all who handle milk, should be to use the most [illegible] as well as to take every precaution known to science to keep the number of [illegible] within the proper limits.

LAW AS TO CAUSE OF DEATH.

Justice Greenbaum, of the Supreme Court, had before him on Saturday, May 24, a somewhat unusual case, and one which well illustrates the seeming contradictions of the law. Margaret [illegible] had brought suit to recover $1,000 on a benefit certificate on the life of a son from the Supreme Commandery of the United Order of the Golden Cross of the World. A jury gave a verdict in her favor, and a motion was brought before Justice Greenbaum to set aside this verdict.

The chief plea of the defense was that Robinson made false statements when admitted to the order and thereby forfeited the insurance. He said that his father had died of pneumonia at the age of thirty-one years, whereas a certificate of death on file with the Board of Health showed that the father had died twenty years ago at the age of thirty-three years from tuberculosis. Section 955 of the Code provides that public records of a class supposed to embrace certificates of death are presumptive evidence of their contents if on file twenty years.

The plaintiff took the ground that the certificate was worthless as evidence to prove the death of the father, because another section of the Code forbids physicians to disclose information obtained in a professional capacity. The plaintiff further wished to call Dr. Walton, who gave the certificate, to testify that the cause of death was not exactly stated in the old certificate, but it was held that Dr. Walton was barred from acting as a witness.

Justice Greenbaum delivered the following opinion: If it be held that Section 955 repealed 834 to the extent that a death certificate made by a physician is competent, then the absurd situation would here be presented of excluding the oral testimony of Dr. Walton, who attended the father of the deceased at the time of his death, and who wrote out the death certificate as to the cause of the father's death, and admitting identical proof from the same source written on a piece of paper called a certificate. The Justice said that the authorities are decided that a physician cannot disclose the cause of death of a patient, and he did not think it was intended to abridge the law sealing the mouth of a physician by letting in evidence his written statement of death because it was filed on record twenty years ago. He was of the opinion that a physician is bound to file such a certificate under the laws, but that the cause of death be established by common law only; he therefore declined to interfere with the verdict. It would appear from this interpretation of the law that a physician's certificate does not count for much, and as he is precluded from giving oral evidence as to the cause of death, the question is, how is the correct cause of death to be discovered?

THE METRIC SYSTEM.

Once again a movement is on the way to introduce the metric system into the United States. A bill is now before Congress to bring about this reform so far as the different departments of the United States Government are concerned. There is a wide divergence of opinion, among the various professions and trades interested, as to the desirability of this course.

Many, perhaps the majority of scientific men, favor the movement, but on the other hand, many influential bodies strenuously protest against the introduction of the metric system into the Government departments. Among those which most vigorously assail the suggested change is the American Society of Mechanical Engineers, which, according to the *Scientific American*, believes that the metric system "will inconvenience and hinder trade and manufacturing, and require an expenditure of time and money that cannot be expressed in figures, sweeping away, as it does, the advantages accruing from the numerous established standards now recognized and universally adopted throughout the country."

Of course, this is one way of looking at the matter, but there is another consideration which is quite as, if not more, important.

The metric system is in use in all countries but the United States and Great Britain, and indeed may be called an international system, and is said to answer its purpose excellently. Although the United States and Great Britain own a large slice of the world, they by no means own sufficient to enable them to control the situation, and it would certainly facilitate international trading if all nations used the same standards.

The metrical system is used by pharmacists, and the Pharmacopœia and Dispensatory are both based on it.

On the whole, it would seem that the adoption of the metric system in this country is indicated upon both scientific and economic grounds.

CRUSADE AGAINST MOSQUITOES IN NEW JERSEY.

In a recent issue of the New York *Tribune* Mr. John B. Smith, State Entomologist for New Jersey, gives an account of the methods which will be employed to fight and, if possible, eradicate the mosquito from that State.

An appropriation of $10,000 was made in the last session of the New Jersey State Legislature for a study of the mosquito problem, but owing to a misconception of the intent of the act—some believing that for the amount appropriated an attempt would be made to rid the State of the mosquito pest—the measure was, in certain quarters, adversely criticised.

The bill really reads "An Act to Provide for an Investigation and Report by the New Jersey Agricultural Experiment Station upon the Mosquito Problem in its Relation to the Sanitary, Agricultural and Other Interests of the State."

It is in the southern part of New Jersey that the mosquito is particularly rampant.

Mr. Smith premises his description of the methods to be employed by stating that the purpose to be kept in view is the permanent eradication of the mosquito. It is easy to kill larvæ by the million with kerosene or other oils; but unless the conditions are changed this killing would have to be done over and over again, and there would be no end to the expenditure of money.

The methods to be employed are as follows: the distribution of the natural enemies of the mosquito larvæ should there be any that are effective. This involves a study of fish, frogs, toads, and other similar creatures, to determine which forms may be made useful in the fight.

Next the matter of drainage, as applied to the immense salt marsh areas, is to be closely studied.

Mr. Smith wishes it to be distinctly understood that the work now in hand is merely a preliminary investigation from which to gather data as to the best means of waging a successful fight against the mosquito.

It is to be questioned whether any scheme other than a thorough drainage of the marshes will have the effect of diminishing the number of mosquitos to an appreciable extent. Naturally, a project so ambitious as this somewhat alarms the Legislature on account of its probable expense, but, even if the sum of money expended were large, the banishment of the mosquito would alone compensate for the expenditure.

In the meantime, it is well to try simpler palliative measures, such as stocking ponds with fish, frogs and toads.

The Housing Question.

In all large cities of the world the problem most difficult to solve is how to house the teeming population in such a manner that health, morality, and decency, may be fitly observed. In New York the difficulty presents itself in its most aggravated form, and figures are daily being gathered testifying to the truth of this statement. In the quarterly issue of *Federation*, the organ of the federation of Churches and Christian organizations in New York city, is an article, by the Rev. Dr. Walter Laidlaw, dealing with the sociological conditions of the Eleventh and Thirteenth Assembly Districts. In these districts 6,369 families, out of 13,657, live in three rooms or less, and only 2,457 have above four rooms. The average is 3.7 rooms to a family. Among the Italians it is 3.2; among the negroes, 3.4 rooms.

There are 50,640 rooms in the apartments, and 17,015 of these have no outside windows.

The total number of private baths is 557; there are twenty-one families with access to a hall-bath and 13,079 tenement families are without bathing facilities. There are but three bath-tubs among 501 Italian families, and the Austrians and Poles have none at all.

Two thousand one hundred and twenty-four families have a private toilet; 4,015 hall toilets, and 7,518 only yard or basement toilets, sanitary conditions which invite both physical and moral pestilence.

One hundred and seventy-one families are without water supply; 1,458 secure water from the ground floor, and only 2,290 have both hot and cold water in their rooms. Various other details are given, but enough has been written to show that the condition of the tenement houses in these districts is extremely bad.

They are, however, typical of the same class of buildings in many parts of the city; indeed, in one or two sections the state of affairs is probably worse.

Sir James Crichton Browne recently delivered an address at Manchester upon "Light and Sanitation," in which the present situation as regards the housing conditions in large cities is eloquently stated.

He said in part: "It is impossible to witness without anxiety the piling-up process that is going on. In the walled towns of yore the houses grew aloft, acrogenously, story on story, because lateral expansion was impossible within the protected area, and in the industrial towns of to-day economic considerations as rigid as stone walls create enclosures within which accommodation can only be found for the crowds that press into them by packing them tier on tier. A general skyward movement is in progress. Artisan dwellings, warehouses, shops, mills, and mansions go on adding cubits to their stature and lengthening and deepening the shades around them. There are streets in London that are like tunnels, courts like damp cellars, rooms innumerable, even in fashionable quarters, that not a glint of sunshine has ever entered. In dealing with that housing problem, which should occupy the most prominent place on the slate of every social reformer, and on the solution of which the best attention should be concentrated, it should be steadily borne in mind that every human habitation or block of habitations should be surrounded by a belt of light as inviolate as the streak of silver sea that surrounds our islands."

The Medical Record has always been an earnest and steady advocate of well-built sanitary dwellings for the poor, for by following this course disease will be prevented, as, probably, it could not be prevented, by any other means.

Tobacco as a Disinfectant.

The subject of tobacco possesses a peculiar and engrossing interest for all sorts and conditions of men. Despite the fact that the general public are continually being warned of the evil effects which will assuredly follow indulgence in the soothing weed, smoking continues in much the same manner as usual. There can be no doubt—as has been pointed out on several occasions in the Medical Record—that smoking to excess, or following the habit when young, is hurtful to the health, and to some people a positive danger. The wisest way is to steer a middle course.

There are, too, enthusiasts with regard to tobacco, and who attribute to the South-American weed all the virtues under the sun. These eulogists, of course, are as much in error as those who deny it any saving grace.

A discussion was raised in an English lay paper of a recent date as to the merits of tobacco as a disinfectant, and much interesting matter was brought forward.

The *Lancet* was called to give, so to speak, expert opinion, and further information on the matter was forthcoming.

The belief that tobacco possesses extraordinary properties in warding off certain diseases of a contagious nature is almost as old as the introduction of smoking into Europe. During the great plague tobacco was largely used for this purpose, and children were encouraged to smoke as a precautionary measure. "In 1888," says the *Lancet*, "Dr. Paul Tassinari of Pisa subjected the germs of various deadly diseases—such as anthrax, cholera, and typhus fever—to the action of dense clouds of imprisoned tobacco-smoke, during periods of 100 to 150 hours, and he came to the conclusion that in most cases, and especially when large cigars had been employed as generators, the development of pathogenic bacteria was either partially or wholly arrested." This experiment, however, by no means proves the case, for, as the *Lancet* says, no one keeps a cigar in his mouth for 100 hours at a time.

Workmen in tobacco factories are often pointed to as examples of the disinfecting properties of tobacco. It is declared that they are immune from epidemics. On the authority of some experiments conducted in France, it would appear that there are some fairly good grounds for this belief, but the investigations have not been carried out to a sufficiently wide extent to justify the passing of any authoritative opinion. The matter is as yet *sub judice*, and will, probably, remain so for an indefinite period. Strong tobacco will keep away insects, and certain mild species of mosquito, but that it will render a person immune to contagion is a theory that will not commend itself to the common sense of a sane man.

News of the Week.

Bacteriological Laboratory of the U. S. Marine Hospital Service. Plans have been prepared and specifications drawn up for the erection of a bacteriological laboratory in Washington under the control of the Marine Hospital service. Under a recent act of Congress $35,000 was appropriated for this purpose, and five acres of ground from the reservation now occupied by the Naval Museum of Hygiene set aside as a site. The laboratory will be used for experimental research which has heretofore been carried on under some difficulties on the top floor of the building devoted to the administration of the Marine Hospital service. The new laboratory to be erected is very convenient in arrangement and attractive in appearance. The plan is wisely drawn so as to provide for future anticipated expansion, the present appropriation being used for the erection of only a part of the projected laboratory. With the proposed amplification of its powers into a national bureau of public health laboratory facilities such as are projected are essential to the proper working of the Marine Hospital service.

The Army Medical Board, which has been in session since April 3 for the examination of candidates for commission in the medical department of the Army, has examined seven classes of twelve men each and found thirteen candidates qualified for appointment. The board will probably conclude its examination of all candidates about the middle of June. There are now sixty-six vacancies in the Army Medical Department, with several more in prospect, caused by retirements from age in the near future.

The Johnston Memorial Hospital in Washington. A committee has been formed for the purpose of carrying out the plan of making the Columbian University Hospital, in Washington, D. C., a memorial to the late Dr. W. W. Johnston of that city. It will be known as the Johnston Memorial Hospital, and the committee will receive contributions for the construction of this building in addition to the funds being expended for this purpose by the trustees of Columbian University.

The New Jersey Sanitorium for Tuberculous Diseases.—An organization of the board of managers of this new sanitorium was effected at a meeting held last week at the office of Dr. Charles J. Kipp of Newark. The following officers were elected: *President,* Dr. Kipp; *vice-president,* Austin Scott, president of Rutgers College; *treasurer,* Colonel Edward A. Stevens of Hoboken; *secretary,* Dr. James S. Green of Elizabeth. The New Jersey Legislature recently appropriated $50,000 for the purchase of a site and erection of buildings.

Further Disproof of Koch's Latest Theory. In a telegram to the New York *Times* of May 24 it is reported that, at the annual meeting of the Royal Agricultural Society of Great Britain, Sir Ernest Clarke, the secretary of the society, announced that tests now completed at the Royal Veterinary College, in regard to the possibility of infecting cattle with human tubercle bacilli, proved that bovines could be so infected and that such bacilli would multiply. "However," said Sir Ernest, "the risk of cattle becoming infected naturally from consumptive humans was very slight."

Christian Science on the No-cure-no-pay Principle. A woman was charged recently in one of the city courts with creating a disturbance in the reading room of a Christian science church. She told the magistrate that she had gone to the church to demand that either $75 which she said she had paid for treatment be returned or that treatment be continued until she was cured. The magistrate told the woman that the proper place to seek redress was in the civil courts and discharged her from custody.

Suing Hospital Patients. Dr. George R. Fowler of Brooklyn recently brought a number of actions against patients who had received professional services at his hands and who, when bills were presented to them, declined to pay on the ground that they were patients at the hospital and that the doctor's services were rendered as a servant of the institution. Dr. Fowler said that he had merely brought the suits to put a stop to a general imposition on physicians by persons who can but will not pay for medical attendance. The actions were brought in the second District Municipal Court in Brooklyn, and eight of them came up for trial one day last week. The amounts ranged from $50 to $600. Two of the actions were settled by the defendants before they were called. In all of the others either judgment was had for the plaintiff or an adjournment was taken.

Maine Medical Association. The fiftieth annual meeting of this association will be held in Portland on June 4, 5 and 6, under the presidency of Dr. Frederick Henry Gerrish of Portland. The annual oration will be delivered on the evening of Thursday, June 4, by Dr. James R. Chadwick of Boston, whose subject will be "Medical Libraries."

Inferior High-priced Milk. In the last weekly report of the Chicago Health Department it is stated that an improvement has recently been noted in the quality of the milk supply which may be expected to continue as a result of the improved pasturage following the recent abundant rains. A curious feature of the examinations during the past fortnight or so, is that the samples of high-priced milk and cream brought to the laboratory by private individuals have averaged much poorer than those collected by the inspector in various parts of the city. The figures last week were 5.9 per cent below grade of inspectors' samples and 9.5 per cent of private samples.

The Queens-Nassau Medical Society.—The annual meeting of this society was held at Mineola, N. Y., on Tuesday, May 27, under the presidency of Dr. William H. Zabriskie.

The American Laryngological, Rhinological and Otological Society.—The eighth annual meeting of this society will be held in Washington, on June 2, 3 and 4, under the presidency of Dr. Charles W. Richardson of Washington. The address of welcome will be delivered by Surgeon-General Sternberg. The secretary of the society is Dr. Wendell C. Phillips of New York City.

Gift to the General Memorial Hospital.—Mrs. Collis P. Huntington has given $100,000 to the General Memorial Hospital for the Treatment of Cancer and Allied Diseases, at Central Park West and One Hundred and Sixth street. This will constitute the "Collis P. Huntington Fund," and the income derived from it will be used to promote pathological research.

A Convert to the Mosquito Theory of Malarial Infection.—Major Buchanan of the Indian Medical Service has recently recounted the history of the conversion of his senior hospital assistant, Joongey Lal, to the belief in mosquitos as the agents for transmitting malaria. Joongey Lal had watched with great interest the dissections of mosquitos, and had observed the development of the malarial parasites in these insects, but still doubted. He asked to be given fever in this way, and then, said he, "I will believe." His request was granted, and he was asked to choose the form he desired. Benign tertian was his selection. *Anopheles* were fed on a case in which gametes of benign tertian were numerous, and, when sample mosquitos were found to contain sporozoites in their salivary glands, Joongey Lal allowed others of the same batch to feed on him. He was bitten by these mosquitos on January 21, 22, 24, and 25. On February 3 he commenced to be unwell, and a parasite was found in his blood. On February 5 and 7 his temperature was over 104° F., and abundant parasites were found and seen by the victim.—*British Medical Journal.*

St. Bartholomew's Clinic.—The new building of this clinic on East Forty-second street was dedicated on Wednesday of last week. The institution is not intended for indoor treatment, but accommodations are provided for patients who may require care in bed for a day or two. The building is six stories in height and has been built in accordance with the latest principles of hospital construction.

Danger in Flashlight Powders.—It is stated in a German medical journal that although the vapor given off by burning magnesium, as used in producing "flashlights" for photographic purposes, is not dangerous, consisting as it does of a mere oxide of the metal, the same cannot be said when the magnesium is combined with chlorate of potash. When this is done, it is stated that the ignition of the compound may give rise to the liberation of chlorine gas or some irritating chlorine compounds, by which severe illness may be caused.—*The Hospital.*

U. S. Examining Surgeons.—A meeting of the U. S. Pension Examining Surgeons will be held at Saratoga Springs, Monday, June 9, the day preceding the meeting of the American Medical Association. All examining surgeons are invited to be present. Those desiring further information may address Dr. William A. Howe, Phelps, N. Y.

Dr. James Rose of Waynesburg, Pa., was killed on May 21 by being struck over the eye with a bottle thrown by a stable boy.

Pathological Society of Philadelphia.—At a stated meeting, held May 22, Dr. G. E. Pfahler read a paper entitled "Indications that Our Present Method of Fumigation Is Faulty," in the course of which he pointed out the inadequacy of formalin as a disinfectant. Drs. M. P. Ravenel and D. J. McCarthy presented a communication entitled "The Diagnostic Value of the Ganglionar Lesions of Hydrophobia," in the course of which they referred to a large number of observations on lower animals, and to several cases in human beings showing the constancy with which invasion by round cells of the capsules of the nerve-cells of the introvertebral and other ganglia takes place, with destructive changes.

Dr. Joseph Sailer exhibited a specimen of aortic and mitral valvular disease, associated with mammoth enlargement of the heart. Drs. W. S. Wadsworth and Wm. G. Spiller exhibited a specimen of multiple hemorrhages of the brain. The specimen was obtained from the body of a man who was found injured on the railroad, and who, without return of consciousness, had general followed by Jacksonian convulsions, with deflection of the eyes to the left side. Operative intervention was discussed, but was deferred for purposes of more accurate localization, but the patient died in the meantime. Post-mortem examination disclosed a large subdural hemorrhage over the right cerebral hemisphere and extravasations of blood into the occipital and frontal lobes. Dr. Wm. G. Spiller exhibited a specimen from a case of cortical deafness, in which atrophy, dependent upon arteriosclerosis, was found in the left temporal convolution. Dr. Spiller exhibited also two brains from idiots. In both of these the cerebrum was small and the convolutions ill marked, and the cerebellum disproportionately large and in part uncovered. Dr. John H. Musser exhibited a specimen of carcinoma of the stomach, in which during life there had been few gastric symptoms, absence of hydrochloric acid from the gastric contents, no anæmia, considerable ascites and an abdominal tumor movable with respiration. Clinically, the possibility of tuberculosis of the stomach was taken into consideration. Drs. Thos. G. Ashton and Coakley read the report of "A Case of Splenic Pseudoleukemia," in which during life there had been an enlarged spleen with marked anæmia.

Examination for Admission into the Marine Hospital Service.—A board of officers will be convened to meet at the Marine Hospital Bureau, Washington, D. C., Monday, June 16, 1902, for the purpose of examining candidates for admission to the grade of assistant surgeon in the U. S. Marine Hospital service. Candidates must be between twenty-one and thirty years of age, graduates of a reputable medical college, and must furnish testimonials from responsible persons as to character. The following is the usual order of examinations: 1, Physical; (2) Oral; (3) Written; (4) Clinical.

Successful candidates will be numbered according to their attainments on examination, and will be commissioned in the same order as vacancies occur. Upon appointment the young officers are, as a rule, first assigned to duty at one of the large marine hospitals, as at Boston, New York, New Orleans, Chicago, or San Francisco. After five years' service, assistant surgeons are entitled to examination for promotion to the grade of passed assistant surgeon. Promotion to the grade of surgeon is made according to seniority, and after due examination as vacancies occur in that grade. Assistant surgeons receive sixteen hundred dollars; passed assistant surgeons, two thousand dollars, and surgeons, twenty-five hundred dollars a year. When quarters are not provided commutation at the rate of thirty, forty, and fifty dollars a month, according to grade, is allowed. All grades above that of assistant surgeon receive longevity pay, ten per centum in addition to the regular salary for every five years' service up to forty per centum after twenty years' service. The tenure of office is permanent. Officers traveling under orders are allowed actual expenses. Further information or invitation to appear before the board of examiners may be obtained by addressing Supervising Surgeon-General, U. S. Marine Hospital Service, Washington, D. C.

Society of the Alumni of the Presbyterian Hospital.—A dinner of this association was held on May 17, at the Arena. Some forty-five members, with honorary members and invited guests, were present. Following the dinner an address was made by Dr. Briddon, and this was followed by other addresses by members of the visiting and consulting staffs of the hospital and by Dr. Booth, president of the St. Luke's Alumni Society. A letter from Dr. Briddon was read presenting to the society a gold medal to be awarded every two years to that member of the Society of the Alumni of the Presbyterian Hospital presenting the most meritorious original essay on a medical, surgical, bacteriological, or pathological subject. The medal is to be awarded by a committee of three from the medical board of the hospital, and the interesting essays are to be published in the Presbyterian Hospital Medical and Surgical Reports. In the event of none of the essays being of sufficient merit, the fund for the medal is to be used for the purchase of medical books for the library of the hospital. The medal to be thus awarded was exhibited. It contains on the obverse a figure of a Greek, [illegible] representing Hippocrates [illegible] his disciples. A vote of thanks was presented to Dr. [illegible] for his kind offer, which was accepted.

Naval Medical Service Filled.—With the recent appointment of Drs. [illegible] as assistant surgeons of the Navy, all vacancies in the naval medical service have been filled. This is the first time since the Civil War that such vacancies have not existed. That they are filled at the present time is due to the fact that two years ago medical men in the Navy were given the same status as was then enjoyed by medical officers of the Army, and under the improved conditions a larger number of better equipped young medical men have presented themselves for examination. This is an excellent illustration of the fact that the character of the professional qualifications in candidates for positions in the government services varies directly with the rewards and emoluments offered.

A Naval Medical School.—It is understood that Surgeon-General Rixey contemplates the establishment at the Naval Museum of Hygiene in Washington, D. C., of a school for naval medical officers modeled on the lines of the Army Medical School which was founded in 1893. Instruction of young medical officers of the Navy in special subjects has in the past been given in a short course at the Naval Hospital in Brooklyn, but this course is recognized as being insufficient, and the instruction to be given in the new school, which it is expected will go into operation in the fall, will be on a much broader basis. Besides giving instruction to newly-appointed medical officers of the Navy in the proper performance of their duties, the school will also serve a purpose as a place where medical officers of longer service returned from a tour of sea duty can refresh their knowledge on special branches and fit themselves for examinations.

It is also understood that Surgeon-General Rixey expects to establish a school for the instruction of the enlisted men connected with the medical department of the Navy, probably at the Navy Yard at Norfolk, Va. A special board of medical officers has for some time been engaged in securing information on this subject and preparing plans for the proposed institution, which will closely follow the lines of the Army School for Hospital Corps Men at Washington Barracks, D. C.

Obituary Notes.—Dr. ALLEN H. HULSHIZER died at Philadelphia on May 19 at the age of fifty-one years. He received his early education at Lafayette College and was graduated from Jefferson Medical College in 1878.

Dr. IDA E. RICHARDSON died in Philadelphia on May 9 at the age of fifty-seven years. She was graduated from the Woman's Medical College of Pennsylvania in 1879 and subsequently became an interne in the Woman's Hospital. At a later period she was appointed Instructor in the Practice of Medicine in the Woman's College. Her practice was confined to gynecology and pediatrics, and she was one of the founders of the West Philadelphia Hospital for Women.

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

[illegible]

LONDON, May [illegible].

[illegible] the epidemic of smallpox has given [illegible] there has been [illegible] for the [illegible] have been expressed [illegible] the spread of the disease. We have [illegible] Mr. W. H. Power's investigations, and which have so largely influenced the authorities in [illegible]. Without denying that the infection may be disseminated through the air, indeed [illegible] it may very well be questioned whether we have not exaggerated the extent of this influence and so far neglected that of other causes. [illegible] the present epidemic [illegible] public health authorities [illegible]. Dr. Thresh, the [illegible] officer for the county of Essex and lecturer on Public Health at the London Hospital, brought the question before the Epidemiological Society last month. The hospital ships of the Asylums Board lie in the Thames just outside his county, and since they were placed there, in 1884, smallpox has been more prevalent than previously in the shore district nearest the ships. His investigations in this and previous epidemics [illegible] point to some central continuous focus of infection corresponding exactly in position with the ships, and the most careful inquiry fails to show any means whereby the continuous flow of infection can occur except on the hypothesis that it is air-borne. Further, he holds that the aggregation of a large number of cases in a limited area is bad for the patients, who are surrounded by an intensely infected area likely to retard or even prevent recovery. He would, therefore, advise the scattering of patients over a large area in properly-equipped [illegible]. Their erection on an [illegible] would employ the minimum number of men and cause the minimum expenditure. No tent should contain above forty patients, and so [illegible] air-borne infection would be prevented. On this point I would interpose that Mr. Power looked upon [illegible] as a possible source of danger, so that Dr. Thresh's researches tend to minimize the influence of air diffusion.

Dr. Thresh's opinions did not commend themselves to the Society. Dr. Newsholme, the eminent M.O.H. for Brighton, said more or less communication no doubt surreptitiously took place between the shore and ships. He would have liked to have had a detailed history of the first dozen or so of cases on which the course of the epidemic would probably depend. Mr. Power did not venture beyond a quarter of a mile as his estimate for air infection, but Dr. Thresh had been speaking of a mile. The hypothesis of aerial diffusion and concentration of the poison threatened to reduce to an impossibility, or an absurdity, the provision of isolation hospitals. Dr. L. Parkes believed in aerial diffusion up to about a mile, and thought smallpox behaved differently from other fevers. Dr. Goodall said the [illegible] of workmen about a hospital was a question of [illegible]. While Dr. Thresh attributed importance to strong winds, Mr. Power had taught that the infection spread farther in calm, foggy weather. He would like to know whether the removal of the hospitals from London had altered the local incidence shown in Mr. Power's maps, or whether the disease still haunted the same localities.

Major W. G. Macpherson gave a statement of his experience in the Gibraltar epidemic of 1893–5. He said he, or his inspectors, visited every case and had been able to trace the infection of every one to its source in Spain or Africa. They were treated in an old building in the center of the city, and afterwards in another only 400 yards outside. But he never had any evidence of aerial infection.

Dr. Richmond, M.O.H. for Hartford, said that out of the two hundred cases in his district there were not forty which could not be accounted for by ordinary personal contact.

More than one member remarked that vaccination and revaccination, properly enforced, would render costly hospital isolation unnecessary. This is, doubtless, the corviction of the profession, and the majority of the public would welcome compulsion. But an invertebrate government has trembled at the noise of fanatics and invented the "conscientious objector."

There is often a deceptive remission of symptoms in the course of acute abdominal diseases so marked that the patient is free from pain and his friends of hope. Too often, however, the relief is only temporary and proves the prelude to rapidly fatal peritonitis. In traumatic cases, with or without rupture of the viscera, this course may be observed as well as in inflammation, ulceration, perforation, or gangrene of the intestines, especially of the appendix vermiformis. Mr. Tubby read a paper at the Medical Society of London on the 28th ult., in which he related cases marked by this period of quiescence. The remission was never a complete cessation of symptoms; one or other would persist and so be a warning of danger. The significance of the pulse has long been recognized, and its ratio to temperature, rigidity or distension studied. Mr. Tubby regarded the presence of leucocytosis as specially indicative of latent mischief, and said blood counts should never be omitted in any suspicious case.

Dr. T. D. Savill said that a pulse-rate over 100 indicated danger, even if the temperature were not raised. Excess of polynuclear cells was surer evidence of suppuration than general leucocytosis.

Dr. J. H. Bryant referred to two cases. One had excess of leucocytes, and there was a large abscess; in the other there was slight leucocytosis, and suppuration did not occur. A high pulse-rate, he thought, indicated operation.

Mr. Hutchinson, Jr., remarked that sometimes a quiescent state had been produced by drugs. He referred to a case of gangrenous intestine, in which there was but the slightest peritonitis, suggesting strangulation of the nerves involved. The evidence of the value of leucocytosis as indicating suppuration was conflicting.

The President, Dr. Allchin, thought the pulse-temperature ratio of great importance in obscure abdominal cases, as pointed out by Dr. Cayley and others.

At the same meeting Lieutenant Lelean, R.A.M.C., gave an account of Bilharzia, illustrating his subject by microscopical preparations and lantern slides. The hatching of the ovarian serum, hitherto considered impossible, he said, he had accomplished, and so removed the chief objection to Sonsino's theory of autoinfection. The adult worm has only been found in the portal system, but the embryos may migrate elsewhere. Invasion may take place through the urethra, but the evidence points rather to the rectum. The disease is rare in women, though they bathe in the tropics as much as the men. Urotropin is useful for the cystitis and hæmaturia, but benzoic acid and methylene blue are the only remedies against the parasite. Lieutenant Lelean gives the urotropin in four-grain doses three times a day for one or two days, follows this up with benzoic acid for three days, and then repeats the methylene.

Surgeon-General Keogh remarked that cases would certainly be coming home from South Africa and might be mistaken for hæmaturia from other causes. Some cases would also be liable to be taken for dysentery.

Colonel Gubbins said he had seen cases invalided home, most of them from Rustenberg district or the Swaziland border.

Dr. Bryant said he had already had three cases. He gave them urotropin without benefit. One improved under carbolic acid.

We have lately had some indications that the educated public is awaking from its apathetic condition respecting vaccination. Dr. T. D. Acland delivered an address on the subject at the Mansion House, at the meeting of the Hospital Saturday Fund.

Mr. A. F. Burridge of the Equity and Law Life Office read an excellent paper on vaccination and smallpox before the Institute of Actuaries on the 28th ult. To increase the popularity of vaccination, he held that every medical man should be recognized as a public vaccinator and be supplied with government lymph. In Lord Cromer's Report on Egypt there is a paragraph on the outbreak of smallpox at Port Said in 1901. The Europeans suffered in an "enormous disproportion," as it was not possible to trace the births of different nationalities and enforce the law. The natives, accordingly, benefited by this law, while Europeans suffered from the neglect of their consuls to notify the births.

There is a prospect that the colleges and medical council may shake hands over their silly quarrel—next session. Dr. Moore's Report to the Senior College is firm as to the rights of that corporation, but not uncompromising as to coming to an understanding between the parties such as would forward the cause of medical education.

I hear that King's College will soon make a similar appeal to that of University College, commented on in my last week's letter. King's College aspires to be as well equipped as its sister. There has always been rivalry between these two institutions. King's College was, in fact, founded expressly to compete with University, which it dubbed the "Godless College," because it was strictly undenominational. King's College was established to compete on a strict Church of England basis.

RESECTION OF A LONG SEGMENT OF INTESTINE.

To the Editor of the Medical Record:

Sir: In the Medical Record of May 3, 1902, among the proceedings of the Section on Surgery of the New York Academy of Medicine, there appears an account of a successful resection of eight feet five and one-half inches of small intestine by Dr. Charles H. Peck, who thought that this was the largest portion of bowel that had been resected in this country. In correction of this assumption I beg to state that, on December 2, 1901, Dr. A. C. Bernays of St. Louis resected nine feet and eleven inches of small intestine for a neoplasm of the mesentery, the specimen being exhibited in Chicago, on December 19, 1901, before the Western Surgical and Gynecological Association. The patient recovered.

Gunshot Wounds of the Knee-Joint by Projectiles of Reduced Caliber.—Louis A. La Garde finds, as a result of his investigations: (1) That the mortality of gunshot injury of the knee-joint in the Civil War was 53.7 per cent., and, as amputation was usually done, all those who recovered escaped with the loss of a limb, unfit for duty; (2) That thirty-three cases of gunshot wounds of the knee, produced by the larger caliber lead bullet in campaign, reported by Reyher and von Bergmann, treated antiseptically, gave a mortality of 11.1 per cent; (3) That sixty-two cases, produced by a variety of missiles, reported by the Surgeon-General since 1898, similarly treated, gave a mortality of 8 per cent., and that 45.6 per cent. of those who recovered were restored to duty; (4) That of nineteen cases in the Santiago campaign, by the reduced caliber bullet, the mortality was *nil*, and that 73.6 per cent. of the wounded recovered fit for duty. It is thus seen that the humane features of the reduced caliber bullet have operated not only in diminishing the mortality in gunshot injuries of the knee from about 8 or 11 per cent. to *nil*, but that it has increased restorations to duty 28 per cent., as shown by comparing the tables of statistics.

Two Cases of Tetanus Following Vaccination.—Lyman Allen reports two fatal cases of tetanus following vaccination in Burlington, Vt. In an endeavor to ascertain the cause of the infection, careful examinations were made of the soil in different places, and the bacillus of tetanus was found. The period of incubation in acute tetanus is from five to nine days, and rarely, if ever, is it as long as twenty-one days, and the longer the incubation period the milder the disease and the more favorable the prognosis. In these two cases nineteen and twenty-one days, respectively, intervened between the vaccination and the onset of symptoms of tetanus, and the rapid course of the disease in each case and the fatal result point to a short period of incubation. It is, therefore, almost impossible that the germs were inoculated at the time of vaccination. This fact, with the positive findings in the animal experiments conducted, makes it practically certain that the disease was caused by lack of care in the after-treatment of the ulcer of vaccination. Vaccination should be considered a surgical procedure and be safeguarded by all antiseptic precautions. The ulcer of vaccination should be protected from infection and trauma as carefully as any other surgical wound, and, to accomplish this, all vaccinated persons should either report regularly to their physician for the proper dressing and cleansing of the ulcer, or be carefully instructed at the time of vaccination as to the precautions necessary to be taken to avoid serious complications.

Journal of the American Medical Association, May 24, 1902.

The Treatment of Inoperable Septic Peritonitis.—Horace G. Wetherill says that the treatment of septic peritonitis by surgical measures on the one hand, or by rational medical measures on the other must be determined in each case first through a carefully-made differential diagnosis as to the source of the infection; second, through an estimate of the apparent virulence and diffusion of the infection, and, [illegible] consideration of the [illegible] cases [illegible] the [illegible] [illegible] the [illegible]. [illegible] from the [illegible] [illegible] and [illegible] to be dangerous in the [illegible] given [illegible] of the [illegible] greater mobility of the [illegible] and [illegible] general [illegible] and of the greater relative [illegible] of their contents, [illegible] and [illegible] of [illegible] and [illegible] plastic changes of the [illegible] tissue. Physiological rest of the intestines favors formation of the [illegible] and [illegible] of [illegible], and is best attained by the [illegible] of an empty bowel and the [illegible] of [illegible] the [illegible]. If symptoms are good [illegible] the [illegible] may be expected [illegible] and [illegible] with the [illegible] a [illegible]. Cases of diffuse peritonitis with [illegible] local and general symptoms must be regarded as being [illegible] as the [illegible] of the patient and the requirements of good surgery both demand that [illegible] surgical measures be not employed where better results may be had with [illegible] and [illegible]. Early operation before diffusion has taken place [illegible] and is [illegible] to be advised if the circumstances be favorable and an experienced surgeon at hand. Interval operations are certainly advisable after recovery from a diffuse peritonitis from any source.

The Evolutionary Aspect of Infectious Diseases, with Especial Reference to the Local Venereal Diseases.—G. Frank Lydston does not regard the gonococcus *per se* as the sole or perhaps even the most important element in the production of a specific urethritis, the conditions governing the evolution of the germ and especially the evolution of virulent properties in a primordially innocuous germ being of far greater moment. And the same applies with equal force to chancroid save that the influence of a definite germ in this disease has not been established. It is the writer's belief that gonorrhœa and chancroid develop *de novo* in the medium afforded by the secretions of the unclean and pathologically contaminated vagina. This development depends upon adaptation changes in innocuous or comparatively non-virulent germs—a spontaneous culture modification. The virulency of the resulting germ production is modified by many conditions, of which the following are most important: (1) Much depends upon the stage of decomposition of the vaginal fluids. The age of the process of germ development is all important. (2) The frequency of coitus. (3) The constitution and habits of the woman. (4) The character of any seminal or other discharge from the male which may be deposited in the vagina. (5) The degree of uncleanliness of the woman. Once elaborated and heteroinoculated upon susceptible soil the results depend upon: (1) The amount and degree of virulence of the infectious germs and their products deposited upon an atrium of infection; (2) The cleanliness, local and constitutional condition, habits and sexual hygiene of the new host; (3) Individual predisposition. This involves individual immunity on the one hand and a tendency to inflammation, suppuration, serpiginous ulceration, phagedena, or gangrene on the other.

New York Medical Journal, May 24, 1902.

Albumin in the Urine—a New Way of Applying Nitric Acid and Other Reagents.—L. Napoleon Boston describes the following plan devised by himself, which has, he claims, several advantages over the usual methods: (1) A pipette is filled for a distance of from one inch to one inch and a half with the urine to be tested. Then this pipette is either carried under a stream of water and then dried by a towel, or all urine is removed from its surface by a damp towel. (2) This pipette, with its contained urine, is placed near the bottom of a bottle containing pure nitric acid, when the pressure of the index finger is lessened and the acid allowed to flow gradually up into the pipette; (3) When the pipette is seen to contain about the same amount of the acid and of the urine the finger is again pressed firmly and the pipette removed from the bottle and held toward the light, on a level with the eye, and, if albumin is present, a distinct white cloud, in the form of a ring, appears at the zone of junction of the urine and acid. This ring is often intensified by placing the pipette in different lights or against a dark background. The hand when placed back of the pipette and carried slowly above and then below the level of the ring, serves this purpose.

Tracheal Injection in the Treatment of Bronchial and Lung Diseases.—Larne D. Rockwell, premising that the prevailing therapy of pulmonary and bronchial affections is unsatisfactory, recommends as more rational the direct application of remedial agents to the mucous membrane of the air passages by means of intratracheal injections. He says he has employed this method in a variety of cases, and is convinced that it is a safe and valuable means of treating diseases of the lungs. He reports two cases. The first was in the person of a man of fifty years whose occupation exposed him to the inhalation of [illegible]. After an attack of influenza in the summer of 1901 he suffered from an annoying and persistent cough which refused to yield to any of the ordinary remedies exhibited in the usual way. The writer employed the tracheal treatment, and using a syringe with a capacity of 4 c.c. and a tube of the proper length and curve threw into the larynx three [illegible] of a solution of oil of eucalyptus, oil of thyme, oil of cassia and iodoform in sterilized albolene. The solution descended directly into the trachea without producing any irritation or cough, and was followed by a good night's rest. The treatment was repeated daily (with frequent interruptions of a day or two) for seven weeks, giving the patient comfortable nights, constant improvement in strength, and finally disappearance of the cough. The second case was that of a man of sixty-three years who had suffered from asthma and winter cough for eight years. He was subjected to treatment by daily intratracheal injections of a solution similar to the one above mentioned continued throughout the winter with marked betterment in every way.

Medical News, May 24, 1902.

How Shall We Treat Sepsis Following Abortion or Labor?—W. O. Henry summarizes this treatment as follows: (1) Remove early with the finger, sharp curette and flushing all débris, decidua, blood clots and sloughing tissue which may be infected, from the uterus and from all raw surfaces of cervix, vagina and vulva. (2) Dry all of these raw surfaces and freely apply to them the 95 per cent carbolic acid, washing away the surplus with sterile water. (3) Unless hemorrhage require leave no tubes or packing of any kind in either vagina or uterus. (4) Have a simple carbolized 2 per cent. vaginal douche used twice a day. (5) Open the bowels freely with calomel, ⅛ grain, every hour for four hours, to be followed by Rochelle salts until sufficient action has occurred. (6) Give quinine, 3 grains every four hours, followed by tincture of the chloride of iron, 15 drops in water. (7) Give good nourishment, with milk, eggs and stimulants every four hours. (8) Let this be the routine *early treatment*. (9) When fixation of the uterus occurs and infiltration takes place in Douglas' cul-de-sac or in the broad ligaments, or when the tubes or ovaries fill with pus in acute cases, open promptly and drain through the vagina. (10) If multiple abscesses occur in the uterine walls, if the walls become badly infected or if necessary in order to secure perfect drainage for a badly infected pelvic cavity, remove the uterus and all else necessary by the vaginal route.

The Treatment of Puerperal Eclampsia.—William E. Parke advocates prophylactic treatment in the albuminuria of pregnancy. The physician should not wait till convulsions occur. The theory, now almost universally accepted, attributes the convulsions of eclampsia to the presence of some toxic agents in the blood. The formation of these toxins should be prevented or, if they have already appeared, their elimination should be favored. Milk is an excellent food for this condition. The bowels, the skin and the kidneys, and even the lungs should all be stimulated to eliminate waste products. Phosphate of soda, a drachm or two daily in a tumbler of hot water before breakfast, and fractional doses of calomel at night, once or twice a week, are indicated. Hot baths for the skin and plenty of water for the kidneys should be taken. Bashaani's mixture is a good diuretic. Exercise in pure air is helpful. If, in spite of all these measures, there is evidence of increasing toxæmia labor should be induced at once. For the treatment of convulsions, venesection is of the greatest value. Inhalations of chloroform can be used to avert the attack. Veratrum viride seems to be helpful in eclampsia. A very weak pulse, however, would contraindicate its use. Chloral and bromide are valuable adjuncts, normal salt solution, either under the skin or injected into the bowel, dilutes the poison in the blood and increases the activity of the kidneys. Two or three drops of croton oil induces prompt action of the bowels. As to the child, after it becomes viable, it is probable that *accouchement forcé* will save more babies than allowing the labor to proceed during convulsive seizures in the natural way.

Philadelphia Medical Journal, May 17, 1902.

The Importance of the Lacrymal Reflex in the Diagnosis between Organic and Hysterical Anæsthesia of the Face.—This interesting observation is made by William G. Spiller. By the term lacrymal reflex he refers to the secretion of tears produced reflexly by irritation. He has examined two cases of hysteria in which the scleral conjunctiva was insensitive, but in which irritation of the conjunctiva did cause the flow of tears, although it did not cause the eyelids to close. Gilles de la Tourette and Pitres have also observed the preservation of the lacrymal reflex in hysterical anæsthesia of the conjunctiva. In order to test the diagnostic importance of this phenomenon, the writer examined two other cases in which anæsthesia of the conjunctiva had existed for some time as a result of the removal of the Gasserian ganglion. During the irritation of the lacrymal apparatus—the most satisfactory method proving to be by irritation of the nostril—little or no increase in the lacrymal secretion was observed. Although the writer does not believe that these few cases establish fully the importance of the lacrymal reflex in diagnosis, he reports them with the hope that others may give the results of their investigations on the subject, and that from the examination of many cases this point may be determined.

Some Reasons for Considering the Vermiform Appendix as a Gland.—Clarence L. Killbourn, in speaking of the development of the appendix, says that it is first seen at the sixth week as a part of a lateral diverticulum, which also forms the colon. This is about the time that the diverticulæ are given off to form the other glands. In the structure of the appendix, far more important than either serous or muscular coats is the submucous layer. It forms the greater part of the appendix and is the bulk or body of the whole structure. This predominating tissue is lymphoid in character. Histologically, the appendix resembles the tonsil, and a microscopical section looks not unlike a tonsil surrounded by a thin muscular coat, and penetrated by a central canal. The appendix may be regarded as an inverted or involuted tonsil. In location and structure the appendix bears the same relation to the pancreas as the tonsil does to the salivary glands. The germicidal properties of the tonsils and their protection of the pharynx are well realized. And in the appendix we must recognize an organ having a similar structure and capable of doing a similar work in its own territory. Its situation is particularly adapted to act upon the contents of the colon, its secretion being able to act immediately on the food as it passes through the cæcum. In considering the pathology of this organ, similarities are noticed toward the diseases of the recognized glands. The writer thinks that the appendix should be accorded a rank equal to that held by the tonsils or salivary glands.

Philadelphia Medical Journal, May 24, 1902.

Note on the Occurrence of Ascites in Solid Abdominal Tumors.—William Osler thinks that the association of solid abdominal tumors with abdominal dropsy is not sufficiently recognized. He reports several of these cases. According to Eden, ascites is the rule with solid tumors of the ovary, and so rare with fibroids of the uterus that its presence almost serves to exclude them. Other forms of tumor may be associated with ascites. The writer has seen a case of leukæmia with recurring ascites. In a case of a solid tumor of the mesentery there was an ascites of moderate degree. The question of operation is an important one. The solid ovarian tumor is usually benign, and recovery after operation may be expected.

The "Fourth Disease" of Dukes, with a Report of an Atypical Outbreak of Scarlet Fever.—J. Hall Pleasants concludes, from his study of this question, that: Dukes has not established the existence of a new exanthematous disease. Under the so-called "fourth disease" he has included cases of undoubted scarlet fever, and probably also cases of rubella. In certain epidemics scarlet fever may present an atypical picture, with many of the classical symptoms absent, rendering a diagnosis difficult or impossible in isolated cases. The short period of infectiveness claimed for the "fourth disease" is alone sufficient to make the question one of practical importance. A perfectly satisfactory classification of the exanthemata can hardly be hoped for until more is known of their etiology. The writer believes that in the meantime we should be slow in accepting so-called new diseases in this group, when the claims for recognition rest upon superficial points.

On a Possible Cause of Meteorism and Partial Intestinal Obstruction, with Remarks on the Use of Eserine in Intestinal Atony.—Frederick A. Packard reports the case of a woman sixty years old with evident malignant stricture of the bowel. There was intense tympanites, but in spite of many fluid movements, no flatus had passed for many days. The writer believed that the explanation of this condition was that the patient had a stricture of the small intestine at a point where the fæces were still fluid, and that on the proximal side of this stricture there was a loop of bowel, so placed that it acted as a trap similar to that employed by plumbers to prevent the entrance of sewer gas through the drain-pipes. This patient was given, hypodermically, 1-150 of a grain of eserine salicylate. This was repeated in two hours. After the second injection a large quantity of fluid fecal matter was passed, together with a large expulsion of gas, and the abdomen became flat and soft. At autopsy the loop, instead of being found in the small intestine, was in the upper part of the sigmoid flexure. The arrangement suggested above had taken place in the colon. It is easy to see how such a loop might readily form in the transverse colon. Perhaps one of the functions of the longitudinal band of fibers in the large bowel is the prevention of such loop formation. Such loops might follow adhesions resulting from any inflammatory condition of the lower abdominal cavity. They might remain symptomless until a weakening of the intestinal walls persisted to such an extent that the resistance offered by the contents of the limbs was sufficient to cause accumulation. Such a loop might also follow the liberation of an incarcerated hernia or the matting together of two adjacent segments of the small bowel through tuberculous peritonitis. The condition mentioned above would be aggravated by the administration of any remedies tending to render fluid the intestinal contents. It is possible that hydragogue cathartics might even cause the formation of such a loop if the bowel were paretic. The various reports of the use of eserine in cases of intestinal atony show the happiest results. According to von Noorden, salicylate of eserine (physostigmine) is best to use, because it can be well preserved in a dry state, and is readily soluble in five parts of water. He states that it is best given in powder with milk sugar.

American Medicine, May 24, 1902.

The Vermiform Appendix as a Cause of Intestinal Obstruction.—J. E. Summers, Jr., believes that intestinal obstruction as a complication of appendicitis is a not common occurrence. It may happen that part of the bowel most concerned in the immediate neighborhood of the inflammation may become paretic on account of the inflammation. A knuckle of small intestine may be so angulated by adhesive inflammation, either to the appendix or parts of the bowel or omentum which are inflamed, as to cause narrowing of its lumen. Peritonitis may cause the ballooning of intestine above the angulation until paralysis of peristalsis ends in complete obstruction. After drainage by incision of an appendiceal abscess, or its discharge into the lumen of the bowel, or the subsidence of all acute symptoms, bands of adhesions may form, so as to make compression of the intestine sufficient to produce obstruction. Then there is post-operative obstruction, dependent upon the formation of adhesions or bands between peritoneal surfaces. A long appendix may become attached by its tip by adhesive inflammation to some point of the peritoneum, so as to form a band or arch, and thus produce intestinal obstruction. The writer reports a case in which a long vermiform appendix surrounded the intestine. The end of the appendix had adhered to the mesentery close to the ileum and curled itself into a constricting ring, completely occluding the bowel.

Alkaline Serum Albumin.—John Aulde draws attention to the germicidal properties of alkaline serum albumin and also to its clinical importance as a factor in the transmission of nerve impulses. No doubt many patients derive benefit from medicines given for some other condition, as when pepsin is ordered with an alkali, when sodium bromide is taken for ovarian neuralgia, or potassium iodid for syphilis, or sodium bicarbonate for acid dyspepsia, since in all these cases the alkali plays an important part in restoring the physiologic equilibrium and making the cells work. A very important point in the question of the expediency of administering stimulants or sedatives as a means of favoring the elimination of waste products, including cytotoxins, is the blood reaction. There has been much persistency in the use of acids, especially in the treatment of digestive disorders. Blood serum loses its germicidal properties when the alkalinity is neutralized. In regard to the second point, the transmission of nerve impulses, it is known that certain molecular changes take place in protoplasm as a result of electric action, chemic action, or the action of light and heat, and that these forces are concerned in the transmission of nerve impulses. The maintenance of the normal alkalinity of the blood is most important, as otherwise the cellular structures would be incapable of functionating. The question of the character and functions of electrons will, undoubtedly, be developed in due time.

Symptomatology, Diagnosis, and Differential Diagnosis of Neuritis.—Sydney Kuh declares that if there is any one symptom which is absolutely pathognomonic for neuritis, it is perceptible enlargement of parts of the nerve-trunk, usually spindle-shaped and often multiple. Generally, both the sensory and motor fibers are affected in disease of the nerves, but sometimes only one of these groups suffers. Pain is most frequently the earliest symptom. It is not, as a rule, superficial, but is rather [illegible] Hysteria is easily distinguished from organic disease of the nerves. [illegible] In neuritis both pain and paræsthesiæ are more or less distinctly intermittent; in neuritis both symptoms are as a rule permanent. In cerebral disease the unilateral occurrence of paralysis of motility and of sensibility, the spasticity and increase of deep reflexes preclude a possibility of neuritis. In spinal disease with symptoms of spasticity this symptom alone would exclude all thoughts of neuritis. Acute anterior poliomyelitis is rare in adults at the age at which multiple neuritis is most likely to occur. Chronic poliomyelitis is also rarely seen in adults. In tabes not complicated by disease of the nerves the latter are not sensitive to pressure, the muscles react normally to electricity, are neither paralyzed nor atrophic. Muscular dystrophy develops very slowly, is progressive and affects several members of one family.

Deutsche medizinische Wochenschrift, May 1, 1902.

Osteal Tendon Transplantation.—Julius Wolff recommends, in tendon transplantation, osteal instead of periosteal insertion, since this more nearly approaches the natural insertion of tendons. The author has carried out osteal insertion in four instances and has obtained better results than by the periosteal method. Furthermore, the most satisfactory correction of deformities is obtained by a transplantation of the tendon of the muscle, which by its action is chiefly responsible for the malposition. For example: in radial paralysis the tendon of the extensor carpi ulnaris is removed from its insertion at the base of the fifth metacarpal bone and inserted, by the osteal method, into the base of the second metacarpal bone, the hand being placed in a position of marked supination and dorsal flexion.

Pathology of Chronic Lead Poisoning.—A. Sæugländer, in the first of a series of articles devoted to this topic, considers the causation of chronic lead poisoning as illustrated in several cases which have come under his observation. Among these is a case which developed from the use of snuff which had been packed in tin foil which contained a large proportion of lead. Most of the patients, however, were persons who, on account of their avocations, were daily brought into contact with this metal. One of these is interesting because of the prominence of cerebral symptoms early in the course of the poisoning. This patient gave a syphilitic history and at first the diagnosis was not entirely clear. The subsequent clinical history and the effect of treatment clearly established the case as one of chronic lead poisoning.

Berliner klinische Wochenschrift, May 5, 1902.

Treatment of Sciatica.—L. Brieger emphasizes the value of the combination of hydrotherapy, massage, and exercise in the treatment of sciatica. When the measures are employed singly the results are unsatisfactory, but their combined employment usually effects a permanent cure. As routine treatment, hot baths, accompanied by massage and followed by a cold douche, give the greatest relief. The hot baths are to be taken at 40° C. (104° F.) and should last fifteen minutes. They should be repeated daily. Exercises should be practised between the baths. Such exercise should be at first very light and subsequently gradually increased. The necessary duration of this treatment varies greatly in different cases. Many are completely cured in two to four weeks; frequently, however, a longer period is necessary. A detailed description of eight cases is submitted.

Hemiplegia.—Max Rothmann concludes that hemiplegia [illegible] the appearance of the paralysis. This [illegible] in certain cases is greatly facilitated by tendon transplantation.

Münchener medicinische Wochenschrift, May 6, 1902.

The Value of the Precipitin Reaction in the Differentiation of Albuminoids.—Rostoski says that the precipitin reaction is of no value in the differentiation of the various albuminoids. It is, however, of service in ascertaining the origin of the albuminoid. Thus, the serum of rabbits inoculated with horses' blood contains precipitins for all the albuminoids of the horses' blood, and it is impossible in this manner to differentiate the albumin from the globulin. Such rabbit serum, however, does not contain precipitins for the albuminoids of the blood of other animals or man. Hence, the reaction differentiates albuminoids of different origin. The same holds true for the Bence-Jones' bodies. The intensity and rapidity of the precipitation is lessened by an alkaline and increased by an acid reaction. A marked concentration of the albuminoid solutions hinders the formation of the precipitate. Furthermore, the presence of salt is necessary for the production of these reactions.

Senile Cutaneous Angioma.—In order to determine the frequency of cutaneous angioma at various periods of life, Julius Raff has examined 500 persons sick with various diseases; 36 per cent. of these showed cutaneous angiomas in greater or less number. Previous to thirty years of age they are somewhat rare, thus in 123 persons between twenty and thirty years of age they were only present in 18.7 per cent.; after forty years of age they become frequent, and after the fiftieth year such angiomas are present in the majority of all persons. They were found in 75 per cent. of the persons examined between sixty and seventy years of age. Leser has recently claimed that the presence of cutaneous angiomas is of importance in the diagnosis of malignant growths. It is apparent that the results of the above observations do not bear out this claim. The histology of these tumors has been much discussed, and at the present time cannot be regarded as entirely definite. It seems certain, however, that in the majority of instances they are to be classified as true angiomas and not as nævi.

Leucocytosis in Some Surgical Diseases, with Especial Reference to Appendicitis.—M. Wassermann says that in acute appendicitis a total leucocytosis of 25,000, and above, is diagnostic of the presence of pus. A study of ten cases show this to be the case, independent of the clinical symptoms present. The absence, however, of such a leucocytosis is not absolute proof of the absence of pus, since two of the cases showed the presence of pus with a relatively low leucocytosis. In such cases the low leucocyte count is, in all probability, chiefly due to two factors: (1) An encapsulated abscess, (2) Diminished resistance on the part of the patient. The leucocytosis of appendicitis is essentially polynuclear neutrophilic in character and differs in no manner from that present in other inflammatory conditions. Apparently no relation exists between the bacterial basis of the appendicitis and the intensity of the leucocytosis. In most other abscesses (nephritic, glandular, prostatic, mastitic and phlegmonous) the leucocyte count is markedly below that present in purulent appendicitis. In mastitis and phlegmonous abscesses, however, when general infection takes place a leucocytosis of a very high grade develops. Likewise, general septicæmia and erysipelas uniformly show a high leucocyte count.

French Journals.

Arsenical Poisoning.—A. Lutaud declares that although arsenic is not found in the human organism it is a very common substance. It is the frequent cause of professional or accidental poisoning. The number of criminal cases has diminished considerably in the last thirty years. This appears to be due to the administrative measures taken against its sale and to the progress of science which has developed methods of determining its presence in the organism. In order to cause serious results or death it is necessary to take from 2 to 10 centigrams of the poison. It is always possible to determine its presence in the body even in the smallest doses. Arsenical poisoning, especially chronic poisoning, causes special lesions, chief among which is fatty degeneration of the liver.—*Journal de Médecine de Paris*, April 27, 1902.

Disinfection of the Hands by Alcohol.—Schaeffer, after experimenting with the various methods of hand disinfection which have been employed up to the present time, has arrived at the following conclusions: The best results are obtained from washing the hands with hot water, and then with alcohol. Next in value is the method of Miculicz, with tincture of soap. Antiseptics do not destroy, to a sufficient degree, the germs on the hands. Soap with marble dust (Schleich's method) gives results no better than washing the hands with plain hot water and soap. Schaeffer advises washing the hands first with very hot water and green soap, scrubbing the hands vigorously with a brush for five minutes. The nails are then to be cleaned and the hands rubbed with a sterilized compress. Finally, brushing the hands for three or five minutes in absolute alcohol. It is a good plan after that to place the hands in a solution of corrosive sublimate.—*La Tribune Médicale*, April 30. 1902

The Dangers of Internal Antisepsis.—Albert Robin believes that the impregnation of the organism with mercurials does not prevent the bacillus of Eberth from infecting the tissues, nor does it attenuate its virulence. Contrary to the opinion of various investigators, the writer is convinced that the employment of mercurials in the treatment of typhoid fever does not bring about intestinal or internal antisepsis. Calomel alone may be employed medicinally in exceptional instances—it may be as a purgative, as a stimulant of the biliary secretion, or as a diuretic when there is indication for any of these effects. But the general mercurials have the serious effect of diminishing the oxidizing functions of the organism—just what we are most in need of in this disease, in order to make the powers of resistance greater against autointoxications. Therefore, the writer believes the use of the general mercurials in typhoid fever are not only without benefit but positively harmful.—*Bulletin Général de Thérapeutique*, April 30, 1902.

Laryngeal Tuberculosis.—Vues states that this affection is one of the commonest of throat diseases. Owing to the researches in this subject in recent years, the diagnosis is not difficult. Nevertheless, its prognosis is not very good. Tuberculosis of the larynx may be primary or secondary. The latter is consecutive to tuberculosis pre existing in other organs. Infection may take place in two ways, from within outward, by the lymphatic or blood route; from without inward, by inspiration of the organisms in the air; they, probably, attack the larynx through a break in the epithelium. Injections of tuberculin aid in the diagnosis in suspected laryngeal tuberculosis, when there are no lesions in other organs. Gazzia advises histological examination of fragments of the ulcer taken from the larynx. During the period of infiltration the voice becomes hoarse, the cough is rough and causes pain. Later appear dysphagia and laryngeal dyspnœa, sometimes necessitating tracheotomy. The general health suffers very much. The treatment may be medical or surgical. Tracheotomy is only a palliative measure, useful in cases of laryngeal stenosis.—*La Policlinique*, May 1, 1902.

Annals of Surgery, May, 1902.

Hour-Glass Stomach.—J. M. Elder reports a case of this nature occurring in a married woman of forty-nine years. The main symptoms were inability to retain food and progressive emaciation. A diagnosis was made of pyloric stenosis, probably due to a malignant growth, and an exploratory laparotomy was advised. An "hour-glass" stomach was found, with a band extending from the central constricting ring up to the right rectus muscle. The band was as wide as the finger, and apparently encircled the stomach. A gastroplasty was done according to the Heinicke-Mikulicz method of operating on the pylorus. The results were successful.

Subcutaneous Injury of the Brachial Plexus.—P. R. Bolton reports two cases of total paralysis of the brachial plexus. In one case a man had fallen from a height, and in the other had been struck by a locomotive. Operation showed in each case that the nerve trunks were included in granulation tissue, the latter then becoming cicatricial tissue, and, associated with this, and possibly due to the increased compression to which the nerves were subjected, degeneration of them and their probable cessation of function. In both the above cases the removal of the cicatricial tissue would have left the nerve ends so widely separated that suturing would have been impossible. The wounds, therefore, closed and healed without incident.

The Curative Effect of Trephining Per Se.—C. J. Aldrich reports two cases trephined for intracranial disease. One was cured, and the other markedly benefited. The first case was one of hemispasm, with loss of consciousness, due to a severe head injury. The second was one of severe headaches following a similar injury six years before. In addition, the patient staggered, became morose, and talked of suicide. There was general failure of the mental powers, but there was no paralysis or failure of sight, taste, or smell. No anæsthesia developed. Both patients were trephined, but in neither was a lesion found, nor were the operations made over areas which the symptoms suggested might have been diseases. The good effects following operations in such cases are, in the opinion of the authors, due, first, to relief from intracranial pressure, and, second, to a marked psychic effect.

A Contribution to the Surgery of Spina Bifida.—Van Buren Knott reports four cases treated by excision. In all the operation was successful. He presents the following conclusions: (1) Owing to the distressing nature of the affliction, the high mortality should not prevent attempts at surgical relief; (2) Meningoceles, meningomyeloceles, and syringomyeloceles may be considerably benefited by operation; (3) The improvement in function cannot with certainty be estimated before operation, and pronounced evidences of nervous disturbance are not a contraindication to excision; (4) Asepsis is absolutely essential, and, though difficult to secure, may be maintained by exercising extreme care; (5) The plan of having the suture lines of the meninges and the overlying tissues on different planes will, in the majority of instances, prevent leakage of cerebrospinal fluid; (6) The suggestion of Pearson, to prevent the escape of this fluid during a prolonged operation, by stuffing the canal with gauze, is valuable; (7) Large bony defects may be effectually closed by muscle much easier than by osteoplastic methods; (8) It is not necessary to keep the child off its back during the healing of the wound, as frequently advised; (9) Children with hydrocephalus, accompanying spina bifida, should not be subjected to operation.

Thoracic Injuries Involving the Lungs.—W. G. Le Boutillier reports two cases coming under his care. The headings of the cases are, respectively, "Rupture of Lung without Fracture of Rib; Distending Pneumothorax Not Relieved by Aspiration," and "Pistol-Shot Wound Penetrating Lung; Excision of Rib for Hæmothorax; Death from Infection with Bacillus Ærogenes Capsulatus." The author reviews the literature of this class of injuries, and concludes: Operative interference is not only justifiable, but imperatively called for (1) In distending pneumothorax from whatever cause; if aspiration or the introduction of a trocar does not give relief, thoracotomy should be done, and the lesions thus ascertained treated in appropriate ways; (2) In large hæmothorax, in cases of fractured ribs, contusions of the thorax without external wound, and penetrating wounds of the thorax without regard to the nature of the weapon producing the injury; (3) In extensive and progressive subcutaneous emphysema after thoracic injuries. The nature and extent of the measures to be resorted to must be determined according to the needs of the particular case. Exploratory operations may be proper in order to determine whether wounds in the lower part of the thorax have penetrated the diaphragm or peritoneum; or to satisfy oneself as to the integrity of the heart or pericardium, as well as of the internal mammary or intercostal arteries; or to provide proper drainage in wounds where infection is suspected.

Archives of Pediatrics, May, 1902.

Spindle-Cell Sarcoma of the Thorax in a Child.—Louis Fischer reports the case of a boy of eight years who presented a growth occupying the region of the thorax usually occupied by the heart. It was removed by operation and found to be a spindle-cell sarcoma in a rather active state of growth. The child died soon after the operation. The chief points of interest about the case were: (1) Displaced heart—the heart being immediately behind the right nipple. The pulsations and the apex beat could be distinctly felt and seen about two finger-breadths behind the right nipple; (2) The intense dyspnœa caused by the presence of the tumor; (3) Con-

[illegible] of the brain [illegible] with the [illegible] to the right side of the [illegible].

Diphtheria of the Conjunctiva Treated by Antitoxin.— [illegible] Improvement in the eye [illegible] in twenty-four hours a very decided change was seen. On the third day the swelling had so far diminished that the child could open the eye, and the membrane was nearly gone. It did not disappear entirely until the sixth day. Diphtheria bacilli were found [illegible] as late as the seventh day, but on the tenth day the eye was entirely well.

A Case of Primary Intestinal Tuberculosis.—M. Nicoll records the case of a little girl of two years who suffered [illegible] and who was poorly nourished. She died very suddenly and the autopsy showed that the death was due to acute pulmonary congestion, [illegible]. The point of interest in the case was the discovery of an ulcer about two inches above the ileocæcal valve, which was found to be tuberculous, although there was no evidence of tuberculosis elsewhere, except in the lymph nodes of the immediate neighborhood. It cannot be doubted that death alone prevented the occurrence of a general miliary tuberculosis. This case constitutes the sixth example of undoubted primary intestinal tuberculosis occurring at the New York Foundling Hospital among many autopsies performed by the author and three other physicians.

The Journal of Tropical Medicine, May 1, 1902.

A Peculiar and Undescribed Affection of the Nose.—J. C. Mitchell of Cape Colony describes a condition which begins with the formation of small hard nodules under the skin, which gradually enlarge, a serous fluid exudes from the surface of the older ones, but there is no ulceration at first. At a later stage there is ulceration with much loss of tissue. The condition in the early and late stages is not painful, and the nodules are almost anæsthetic. In none of the cases reported was the mucous membranes of the mouth, fauces or pharynx affected, though that of the anterior part of the nose was. There was no history or sign of syphilis in the cases. There was marked resistance to iodide of potassium. The writer asks whether the affection was rhinosclerosis.

A Theory to Explain How Man and the Anopheles Originally Became Infected with the Malarial Germ.—Albert J. Chalmers thus summarizes his ideas on the subject: By the action of the digestive juices the protozoa which enter the digestive tract of higher animals find themselves weeded out into those which can resist the juice with immunity and those which cannot. Those of the latter which do not seek further protection die out; the others seek protection by getting under cover of the lining cells of the digestive tract. Those which pass under the cells into the mucous membrane find new foes, to avoid which they enter the red blood cells. The gnat now swallows the red blood cell containing the parasite. The parasite again finds itself in a digestive tract with juices, and again protects itself by passing under the mucous membrane, and to reproduce its species breaks up into a large number of blasts.

Smallpox and Vaccination in Bangkok.—P. A. Nightingale says that the Asiatic resident in the capital of Siam forms a striking object lesson to the conscientious objector in Britain. Though there is no law dealing with the subject, the upper classes almost invariably employ European medical men to vaccinate their children during the cooler months of the year, while the middle classes save up their money and buy the lymph themselves, the mother or Buddhist priest performing the operation. For the lower and poorer classes the Government is beginning to open free vaccination stations. Of course, smallpox is always endemic, and from time to time epidemic, in Bangkok, but, judging from the yearly number of cases which come under one's personal supervision, it is undoubtedly dying out, although the general sanitation connected with the lives of the lower classes is not improving at the same rate.

The Subcutaneous Injection of Quinine.—Charles A. Bentley, in an experience of hundreds of injections of quinine, has only once seen any ulceration following the injection, and that was in a case when he was obliged to use an old hypodermic syringe which could not be rendered antiseptic. Before giving the injection the skin is well rubbed with a 1 in 20 carbolic lotion. Immediately after filling the syringe with the recently-made quinine solution, the author plunges the needle into pure carbolic acid, and then thrusts it deeply into the tissues. After withdrawing the needle and rubbing in the injection, he touches the point of entrance with a camel's-hair brush or small swab dipped in pure carbolic acid, and finishes by an application of carbolic oil. He uses a solution of quinine sulphate made as follows: Quin. sulph. [illegible] gr., acid tartaric [illegible] gr., water to 1 oz. Of this he gives [illegible] to adults and [illegible] to children. In many cases he finds that quinine given by the mouth even in enormous doses is apparently not absorbed in sufficient amount. In such conditions hypodermic medication is a necessity for curative as well as therapeutic [illegible].

The Edinburgh Medical Journal, May, 1902.

On the Symptoms and Diagnosis of Carcinoma of the Hepatic Flexure of the Colon.—A. Ernest Maylard thus concludes in regard to the symptoms which may be taken as suggestive of disease in this particular region: (1) The persistence of digestive derangements, in association with other symptoms indicative of colon disease. (2) The order in which these symptoms arise, first in connection with the bowel and secondarily in connection with the stomach. (3) The symptoms associated with attacks of hepatic flexure obstruction are acuter than those connected with obstruction more distally situated, and do not usually occur until the patient has already shown signs of constitutional disease. (4) Pain is a commoner and more acutely felt symptom in disease of the cæcum, ascending colon and hepatic flexure than when the growth attacks other segments of the large bowel. Further, the pain is usually felt over the seat of the disease. (5) While the symptoms may suggest disease of the colon up to and including the hepatic flexure, the absence of any tangible growth in the right iliac and lumbar regions will point to implication of the flexure.

The Use and Abuse of Ether as a General Anæsthetic.—R. J. Probyn-Williams believes ether to be much safer than chloroform in the majority of cases, but considers its abuse under the following heads: (1) It is given to unsuitable subjects, as those suffering from advanced atheroma, or from thoracic aneurysm, or to those with the mucous membrane of the respiratory tract in a delicate or inflamed condition. (2) Ether is unsuitable as an anæsthetic in certain operations, as when the secretion of much mucus and saliva would be a great hindrance to the operator, or when it is desired that the part should be as bloodless as possible. For the performance of some abdominal operations the deep and free breathing embarrasses the surgeon. (3) Pushing the drug beyond all necessary limits and soaking the patient is one of the gravest forms of abuse of ether. (4) Perhaps the commonest form of abuse of ether is that in which its administration, though eminently suitable for the beginning of the operation, is continued too long. By this means the patient may gradually become "water logged" with secretion, and be in a very favorable condition for the supervention of bronchitis on his return to consciousness. Again the stimulating effect of the ether may mask the shock which a prolonged operation is really causing. The bronchitis and bronchopneumonia which occasionally follow the inhalation of ether may almost always be avoided by keeping the patient warm in bed and out of reach of all draughts of cold air.

Iodine as a Specific Remedy for Surgical Tuberculosis.—Margarethe Hermansen holds that a permanent cure might be obtained in tuberculosis if iodine were given rationally in large doses, and for a very long period, at regular intervals, several times a year, the treatment being repeated should there be the least sign of recurrence. In nine cases of surgical tuberculosis in which operative treatment had had no effect in arresting the disease, the improvement obtained was very marked. Whether the cure is permanent it is not as yet possible to decide as not more than one to one and a half years has elapsed since the first patients stopped the treatment. The iodine was given in the old form, often used against scrofula: Inf. rhei alkalini, sol. pot. tartrat., tinct. cinchon. comp. aa. gram 30, sol. iod. spirit. (5 per cent. iodum), gram 15, tinct. pomi ferratæ, gram 20. One teaspoonful of this mixture was given three times a day, but so that the patients began with half teaspoonful doses, reaching the larger doses in the course of three or four days. The treatment was continued for two to six months, abandoned for a time, taken up again for two to three months, and so on until the disease seemed to be extinguished.—*Medical Press and Circular.*

Book Reviews.

CONTRIBUTIONS TO PRACTICAL MEDICINE. By Sir JAMES SAWYER, Knt., M.D. (Lond.); F.R.C.P. (Lond.); F.R.S. (Edin.); F.S.A.; Senior Consulting Physician to the Queen's Hospital; formerly a Professor of Medicine, Professor of Materia Medica and Therapeutics, and Professor of Pathology in the Queen's College, Physician to the Birmingham and Midland Hospital for Sick Children, President of the Midland Medical Society, Vice-President of the New Sydenham Society, and President of the Clinical Board of the General and Queen's Hospital, etc. Third Edition: Revised and enlarged. 209 pages. Birmingham: Cornish Brothers, 1902.

IN the third edition of this work we note a few changes, chiefly the addition of some new articles, the omission of a few, and a general revision of the whole. The author's aim is to give some practical aid to the practitioner, and to let him benefit by his large clinical experience. Among the chapters we find useful advice on such live topics as Insomnia, Habitual Constipation, Backache, Hemorrhoids, Eczema, Chorea and Asthma. The text is concise and to the point, and, above all, eminently practical. In other words, it is a collection of essays such as an active clinician would select as representative of his most useful writings.

TEXTBOOK OF ANATOMY AND PHYSIOLOGY FOR NURSES. Compiled by DIANA CLIFFORD KIMBER, graduate of Bellevue Training School; Assistant Superintendent, New York City Training School, Blackwell's Island, N. Y.; formerly Assistant Superintendent Illinois Training School, Chicago, Ill. Pp. 276. New York: The Macmillan Company, London: Macmillan & Co., Ltd., 1902.

THE recent advances in histology and physiology have rendered necessary a revision of the above volume, the first edition of which appeared about seven years ago. The chapters on the Nervous System and Special Senses have been altered to a great extent, while minor changes occur elsewhere. The recasting has necessitated the incorporation of a number of new drawings, and there have been wisely added to the English weights and measures their metric equivalents. The descriptions are brief but clear, and contain what is of special importance to nurses, and cover the subjects treated in a sufficiently complete manner. The author has availed herself of the assistance of physicians specially interested in these branches, and in so doing has placed the stamp of authority on the text. The work can be safely recommended as one which is accurate, concise and fitting the uses for which it is intended.

TRANSACTIONS OF THE NATIONAL ASSOCIATION FOR THE STUDY OF EPILEPSY AND THE CARE AND TREATMENT OF EPILEPTICS. 1901. Copies may be had bound, $1.50; paper-covered, $1.00, by application to the Secretary, Dr. Wm. P. Spratling, Craig Colony, Sonyea, N. Y.

THE first annual meeting of this body was held at Washington in May, 1901. The volumes of transactions indicates the status of epileptics in many countries. There are papers from Mexico, Brazil, England, Germany, Belgium, Switzerland, Sweden, Russia, Italy, Turkey, India, Japan and Australia, as well as papers telling of the progress made in the care of these unfortunates in various States in America, Ohio, New York, Massachusetts, New Jersey, Texas, Pennsylvania, Missouri, California, Illinois, Connecticut, Virginia and North Carolina. The world-wide interest taken in the movement and its extent are well illustrated by a reference to the following list of papers: President Letchworth's Address; Ohio Hospital for Epileptics, Address of General Roeliff Brinkerhoff, Address of Mr. I. F. Mack; "Epilepsy," by Frederick Peterson, M.D.; "One Point of View," by Sarah Dall Munro; "An Ideal Colony for Epileptics and the Necessity for the Broader Treatment of Epilepsy," by William P. Spratling, M.D.; "State Care of Epileptics in Massachusetts," by William N. Bullard, M.D.; "What New Jersey Has Done for the Epileptic," by Henry M. Weeks, M.D.; "The Founding of a State Institution for Epileptics in Texas," by B. M. Worsham, M.D.; "The Condition of Epileptics in Pennsylvania," by Wharton Sinkler, M.D.; "Emmaus," by W. J. Alexander, M.D.; "The State Care of Epileptics in California," by Antrim Edgar Osborne, M.D.; "Sketch of the Project to Establish a Colony for Epileptics in Illinois," by Miss Julia C. Lathrop; "The Present Status of Epileptics in Connecticut and the Future Outlook for Their Proper Care and Treatment," by Max Mailhouse, M.D.; "The Present Status of Epileptics in Virginia," by William Francis Drewry, M.D.; "Epileptics in North Carolina," by C. B. Denson; "Report on the Treatment of Epileptics in Mexico," by Secundino Sosa, M.D.; "Treatment of Epileptics in Brazil," by W. Haoelburg, M.D.; "Notes Regarding the Treatment of Epilepsy in Brazil," by Jwar Carlos Fixeui Brandao, M.D.; "The National Society for Employment of Epileptics, England," by G. Penn Gaskell; "The Care of Epileptics and the Outlook in the British Isles," by William Aldren Turner, M.D.; "Bethel, near Bielefeld," by Pastor Siebold and Dr. Huchmeirer; "The Care of Epileptics in Belgium," by Jules Morel, M.D.; "The Care and Treatment of Epileptics in Switzerland," by Professor F. Kolle and Dr. Th. Kolle; "Report from Sweden," by Professor Oskar Medin, M.D.; "The State of Epileptics in Russia," by Professor Paul Kovalevsky; "Report from Italy," by Professor Giovanni Mingazzini; "Report from Turkey," by Dr. S. C. Zavitzianos; "Report from India," by Dr. Arnold Caddy, F.O.C.S.; "Report from Japan," by W. Norton Whitney, M.D.; "The Outlook in Australia," by Miss Alice Henry; "Minutes and Discussions." The volume contains half-tone illustrations of the Craig Colony, the Massachusetts Hospital for Epileptics, and Chalfont St. Peter, with maps of the New Jersey State Village for Epileptics and the Epileptic Colony at Abilene, Tex. The next meeting of this association is to be held at the Academy of Medicine in New York City early in November of this year, under the presidency of Dr. Frederick Peterson.

SELECTED ESSAYS AND ADDRESSES OF Sir JAMES PAGET. Edited by STEPHEN PAGET, F.R.C.S. 8vo, pp. 445. London and New York: Longmans, Green & Co., 1902.

THE title of this work is in itself a more than ordinary promise for the reader. Within the compass of a comparatively few pages is grouped a varied and entertaining collection of addresses and essays, which must appeal in a very direct way to the thoughtful scientific student. Sir James Paget was not only a painstaking pathologist, a successul surgeon, a careful student, but an accurate observer of Nature's processes in health and disease. The body for him was an open book in which he searched for such facts as could be utilized by the man who wished to think for himself and to apply his knowledge in a direct and practical way. Thus the descriptions of diseased processes are wonderfully accurate and expand themselves suggestively in numerous and widespread directions. Dealing with general principles, he was always broad in his applications and logically accurate in his deductions. No one can read this volume without being strongly impressed with the idea that the author of the different essays was a master in his way, constantly advancing new ideas and throwing new light on old ones. Twenty-five practical topics are discussed, each and all of which are worthy of careful reading. Particularly is this the case with those on Senile Scrofula—the cases which bone-setters cure—Stammering Bladders, Sexual Hypochondriasis, Diseases of the Mammary Areolar, Osteitis Deformans, Periostitis following sprains and errors in the chronometry of life. At the risk of making an invidious comparison, there would appear to be more of thought and suggestion in this admirable essay than in all the others combined. But in this matter the student can judge for himself, after a careful perusal of the student work, any patron of which will be likely to interest and edify him. It is one of those volumes which a practitioner can read with profit at any time and for recreation at all times.

THE FOUR EPOCHS OF WOMAN'S LIFE: A STUDY IN HYGIENE. By ANNA M. GALBRAITH, M.D., Author of "Hygiene and Physical Culture for Women," etc., with an introductory note by JOHN H. MUSSER, M.D., Professor of clinical Medicine, University of Pennsylvania. Pp. 200. Philadelphia and London: W. B. Saunders & Company, 1901.

THIS useful little book is divided into four parts. The first, including five chapters, dealing with maidenhood, treats of the anatomy and physiology of the female generative organs, anomalies of menstruation and marriage. Part II, on marriage, deals with a delicate subject in a plain, straightforward way, which is highly commendable. The author does not mince her words, but the most prudish cannot object to her words. The chapters in maternity deal with pregnancy, parturition, the puerperium and the new-born infant, and her clear, but concise Part IV, on the menopause, presents an excellent resumé of this important subject. The concluding chapter, entitled "Hints for Home Treatment," may be read with profit by physicians as well as by the laity. We confess that we opened this unassuming volume, expecting to find only another of the many popular household guides which flood the market. For entertaining this preconceived notion we offer our sincere apologies. On the contrary, it is a first-rate book, and if its maxims were generally heeded, the sphere of gynecology would be greatly contracted. The author must be not only a wise physician, but a good woman.

Society Reports.

NEW YORK PATHOLOGICAL SOCIETY

Stated Meeting, Held March 12, 1902

James Ewing, M.D., President.

A Rare Tumor.—Dr. Charles W. Field presented the specimen. The patient was a female, fifty-six years of age, a widow with three children. The history of the case was negative, except that for some time she had suffered from a hacking cough, and her strength had always been weak. She had been losing strength for two years. Pulmonary symptoms afterwards developed, but there was at this time no vomiting or gastric disturbance. The woman had been admitted to the Presbyterian Hospital on December 20, 1901, after having been affected by nausea and diarrhœa for three weeks. A physical examination made on January 27 showed marked adhesions over the whole of the right lung. The patient continued to grow worse and died soon afterwards, having previously vomited a large quantity of bloody serum.

At the autopsy a very thorough examination was made of all the organs, and it was found that the pleura was very much thickened, apparently by a tuberculous lesion. On sectioning the thickened mass, however, it was found to be a new growth of alveolar type, probably to be classed with the primary endotheliomata of the serous cavities. There was also found a tumor, involving the optic nerves, which was of the same morphological type. The only indication of this new growth, from a clinical point of view, had been headache, of which she complained while in the hospital. The exact site of the origin of the new growth was, therefore, somewhat difficult to ascertain, but it seemed probable that the pleural tumor was primary and that of the optic nerve secondary, though the existence of two tumors, developing simultaneously, was not impossible.

Dr. John H. Larkin remarked that, from microscopical examination, he thought it probable that the tumor might be primary in the optic nerve, but the exact decision of the question was so difficult that he suggested that the sections should be referred to the committee on microscopy.

A Case of Anthrax.—Dr. L. T. LeWald reported this case. The patient, an Italian, fifty-eight years of age, had been employed as a stevedore, and in this capacity had been engaged in unloading sheeps' hides. He had been admitted to the erysipelas pavilion, Bellevue Hospital, on March 1, 1902. Three days before he had noticed a small pimple on the submaxillary region. On the following day he was seriously ill, and unable to go to work. On the third day he was admitted to the hospital. His temperature then was 102°, and it rose rapidly to 105° F. Afterwards it dropped to subnormal, but the man continued to grow worse, and died on the day following his admission. When he was admitted the only lesion which was noticed was a small ulcerated area, about half an inch in diameter, with a dark eschar in the center surrounded by a number of small blebs and a diffuse redness. There was considerable œdema of the face and neck, and this spread rapidly to the chest, and also to the forehead to such an extent in the latter direction that it completely closed the right eye. Afterwards, signs of cyanosis developed, and death occurred about twenty-four hours after the man had been admitted. A smear was made from the wound in the neck a few hours before death, and the examination made at the laboratory confirmed the diagnosis of anthrax. The autopsy was obtained forty-eight hours later, and showed the following conditions: The body was well nourished, and rigor mortis marked. On the right side of the neck, in the submaxillary region, thee was a small ulcer covered by a slight scab. In the surrounding tissue there were a number of small blebs containing a slightly serous fluid. There were marked swelling and œdema of the face and chest. The brain showed intense congestion. The heart was of normal size. The left ventricle was contracted, the right ventricle dilated. The lungs were congested, and the liver showed remains of a few old adhesions. The kidneys showed a slight degree of chronic nephritis. The spleen and pancreas were normal. The stomach was dilated, and the mucous membrane showed signs of chronic gastritis. The epiglottis was markedly œdematous, in fact, sufficiently so to account for death. Smears taken from the left ventricle of the heart showed a considerable number of large bacilli of the anthrax type, and the culture from the same developed anthrax. Cultures from the spleen also showed anthrax bacilli, as did likewise cultures and microscopic examinations of stained sections of the liver. There was very slight parenchymatous degeneration of the liver, and of the kidneys on microscopic examination. The lungs and spleen showed acute hyperæmia. The subcutaneous tissue surrounding the areas of infection was almost necrotic.

The points of special interest in the case were the mode of infection, apparently derived directly from the handling of hides, the widespread œdema, starting in the immediate vicinity of the wound of entrance, and resulting by direct extension in œdema of the larynx and death, the absence of acute hyperplasia of the spleen or other ordinary evidence of a severe septicæmia, although anthrax bacilli were found in the liver and spleen at the autopsy.

Dr. Conner said his experience had been that anthrax was much less infequent in this city than was commonly supposed, and this just seemed to be the type of men among whom the disease developed, *i. e.*, longshoremen whose duty it was to handle hides. Within the last three or four years four or five cases had come into the dispensary of the Hudson Street Hospital. Singularly good results had been obtained from early, radical excision. As the prognosis depended largely on early recognition of the disease, it was well to emphasize the fact that cases of the kind were not uncommon, and that they were likely to be met with in the dispensary rather than in the hospital ward.

Dr. Ewing asked if any bacteriological examination of the blood had been made.

Dr. Le Wald replied that no such examination had been made during life.

Dr. Ewing remarked that it was desirable that the blood should be tested with a view to ascertain whether or not the disease was a form of septicæmia. It was all the more important to determine the presence or absence of the bacilli in the blood because of the various conflicting reports which had recently been published.

Congenital Stenosis of the Aorta at the Isthmus.—Dr. Libman presented this specimen, which, he said, was a striking example of a type of congenital cardiac lesion compatible with long life. According to Vierordt, there were about one hundred and thirty cases of the malformation on record, it being second in frequency to pulmonary stenosis. The average duration of life was thirty-four years, though one person so affected had lived to be ninety-two years old. The stenosis usually occurred at the isthmus, the ductus remaining more or less open or being closed. The exact site was at the opening of the ductus, just below or above it. The stenosis might be ring-like or funnel-shaped. All degrees of contraction occurred down to complete occlusion, fourteen cases of occlusion being on record. The collateral circulation was carried on mainly by branches of the subclavian arteries, communicating with the intercostal arteries, and with some of the branches of the external iliacs. The development of large anastomosing arteries under the skin of the chest and abdomen was a natural result. The diagnosis could be made in adults rather readily, but hardly in young children, in whom the large subcutaneous arteries were well developed. The diagnostic signs were: hypertrophy of the left ventricle; a systolic murmur heard over any part of the heart, usually loudest at the base or at the apex; the disparity between the pulsation of the arteries of the upper and lower extremities; and the presence of pulsating vessels under the skin of the chest and abdomen in which the wave was from above downwards. This last reservation was made because of the existence of a case published by Türk, in which all the signs of aortic stenosis were found, but the pulsation in the subcutaneous vessels was from below upwards, and the arterial pulsations in the lower extremities were more marked than in the upper. A diagnosis was made of obstruction of the large vessels arising from the arch of the aorta, due to specific arterial changes. This was confirmed by the autopsy.

The specimen presented had been obtained at the post-mortem examination of a man, sixty-three years of age, who had been admitted on November 1, 1901, to the service of Dr. Rudisch in the Mount Sinai Hospital. The family history was negative. For five years he had suffered from dyspnœa and palpitation. There was no history of syphilis or gonorrhœa. There was a marked tobacco habit and a moderate alcoholic habit. For five months he had suffered from dyspnœa, palpitation, œdema of the legs, and diminution of the volume of urine, and had been treated at various hospitals without relief. He was then coughing and expectorating much mucopurulent material.

The finger tips were cyanotic. There was marked general œdema. Subcrepitant râles were present over both lungs, with friction râles at the right base. The apex-beat of the heart was at the fifth space, two and one-half finger breadths outside the mammillary line (16 cm. from the median line). The left border was 17 cm. from the median line, and the right border, 4 cm. to the right of this line. There was a systolic murmur at the apex, not transmitted to the left, heard very well in the fourth space to the left of the sternum. It was not audible in the vessels of the neck. The pulse was 90. There was moderate sclerosis of arteries. The liver and spleen were enlarged. The urine was diminished in quantity; was clear, acid, and had a specific gravity of 1,022. It contained 1 per cent. of albumin, and hyaline casts. The subsequent history was the usual one in cases of disturbed compensation from other causes. The patient died from an intercurrent erysipelas on February 1, 1902.

On post-mortem examination there was found marked œdema of the entire body. Under the skin of the anterior thoracic and abdominal walls was a mass of varicose arteries, varying in size from ⅓ to 1 cm. in diameter. The walls of these arteries were thickened, and some were completely occluded. In the anterior mediastinum was an accessory thyroid. The heart weighed 730 grams. The well of the right ventricle measured 1.2 cm. in thickness. The pulmonary artery was notably dilated. The wall of the left ventricle measured 2.4 cm. in diameter. The aorta, at its origin, measured 5.8 cm. in circumference; at the origin of the large vessels, 14 cm.; at the isthmus, 6 mm. in diameter; beyond the isthmus, 9½ cm. in circumference; at the lower part of the thoracic aorta, 6 cm. The abdominal aorta at its upper part measured 5 cm. in circumference; at the lower part, 4.8 cm. The right iliac measured 2.9 cm. in circumference; the left, about the same. The innominate artery at its origin measured 14 cm. in circumference; the left carotid, 5 cm.; and the left subclavian, 4 cm. It would be noted that there was considerable stenosis at the isthmus, with dilatation in front, of the isthmus and below it. The left carotid and subclavian arteries were dilated to twice their normal size. The arch of the aorta at its origin showed but moderate atheroma, as did also the coronary arteries. Directly in front of the stenosis was a thick spur of calcerous material and in the dilatation beyond the stenosis the aorta showed very marked atheroma. The remainder of the aorta and the peripheral vessels showed moderate atheromatous changes. The spleen was much enlarged, weighing thirteen ounces, and the liver, which presented the changes of chronic congestion with some cirrhosis, weighed four pounds.

As a counterpart to this case, Dr. Libman showed a specimen of stenosis of the isthmus of the aorta from a child one and a half years old, which died in the service of Dr. Koplik some eighteen months age. In that case the isthmus of the aorta was contracted only to about half its normal size, and there were no atheromatous changes present. There was no subcutaneous collateral arterial circulation yet evident.

Dr. Conner inquired whether dilatation below the stenosis was at all common. It seemed a strange and inexplicable condition.

Dr. Libman said that in these cases various conditions of the aorta below the stenosis had been found. It had either been normal, stenosed, or, as in this instance, dilated. He imagined that the cause of the dilatation was the effort of the blood to get back into the arch of the aorta. It seemed probable that little or no blood could be propelled into the thoracic aorta, and, therefore, the collateral circulation through the intercostal arteries might be carrying enough blood into the thoracic aorta to dilate it. To corroborate this view he pointed out that the intercostal arteries, which arose from the dilated portion, were much larger than those arising from the lower part of the thoracic aorta and from the abdominal aorta, and said that the valvular arrangement on the distal side of the stenosis indicated distinctly that the stenosis was not due to cicatrization of atheromatous ulcers, a condition which one might be expected to exclude in such a case.

A Case of Hodgkin's Disease.—Dr. E. L. Dow presented this case. It was one which had been observed in the wards of Bellevue Hospital, and regarded as a typical case of Hodgkin's disease, remarkable for the unusual ulceration of the tonsils. The patient was a laborer, forty-five years old, who had suffered from no disease except pneumonia some eighteen years previous to his admission. There was no history of syphilis. For the past five years he had not been as strong as usual nor able to carry out his regular work. The year before his admisson to the hospital he had noticed a small swelling under the angle of the right jaw. This had slowly increased in size, and seven months later he had noticed other hard swellings on the left side of the neck and in both groins. With the appearance of these groin tumors he had noted some difficulty in breathing. The tumors were painless. For the past seven months they had been rapidly increasing in size, and were then very large, filling up the entire lateral aspect of the neck, and forming large masses in the groin. Swallowing was difficult and painful. The expectoration had been, at times, blood-tinged and mucopurulent. He had not lost flesh up to the time of his admission to the hospital. When admitted, the tumors were found to be circumscribed, irregularly spherical masses, quite uniformly firm and elastic, without any evidence of suppuration. The skin was freely movable over them. In the neck they were situated immediately under the lower jaw, on the floor of the mouth, and below the ears, pushing the chin up so that opening of the mouth was limited. In each groin the tumors were of a similar character, with discrete nodules the size of a large fist. In the axillæ were similar swellings the size of an English walnut. Indistinct masses could be palpated through the abdominal wall in the iliac and lumbar regions. The patient appeared fairly well nourished but anæmic. The dyspnœa was extreme and the breathing stridulous. The jaws could not be separated sufficiently for a pharyngeal examination. The heart, lungs, liver and spleen showed no marked abnormalities. On admission his temperature was 101.6°F; pulse, 120; respirations, 30. During his stay in the hospital he had an irregular temperature, varying from 100° to 103°. Examination of the blood after admission revealed 3,600,000 red cells and 2,900 whites to the cubic centimeter. The number of leucocytes remained low until his death. The larynx was normal. The sputum examination showed no tubercle bacilli. While in the hospital the dyspnœa and difficulty in swallowing became so great that he took no food voluntarily. Death was due to pulmonary œdema.

The autopsy, six hours after death, showed a fairly well-nourished body and slight œdema of the legs. In the cervical, inguinal, iliac, lumbar and mesenteric regions were found the tumors previously mentioned. The secondary and tertiary lymph nodes were not involved. Each of those in the inguinal region weighed [illegible] ounces, and was composed of numerous lymph nodes enlarged and bound tightly together. Everywhere the nodes were discrete. In the cross section they showed little fibrous structure. No evidence of suppuration existed, though some of the nodes broke down under pressure. The anterior mediastinum contained a few large lymph nodes, the posterior mediastinum contained many nodes, the size of English walnuts, which extended 'round the roots of each lung, forming masses the size of a fist. The bronchi, trachea, and larynx were intensely congested. The tonsils were deeply ulcerated and hyperplastic, and the entire pharyngeal lymphoid tissue was markedly hyperplastic. Chronic changes were found in the kidney. The intestines showed hyperplasia of Peyer's patches and solitary lymph nodes. One Peyer's patch projected a centimeter into the lumen of the intestine, looking very much like a small mushroom. The surface was ulcerated and there was a postmortem invagination of this portion of the intestine. Microscopic examination of the ulcerated tonsils and lymph nodes revealed only round cell growth, with hyperplasia in all but the iliac, lumbar and mesenteric nodes. There was no evidence of tuberculosis.

The deep ulceration of the tonsils apparently occurred more frequently in those cases running an acute course. A number of observers had noted such a condition in connection with acute inflammations of the throat.

Dr. Wood observed that in some of the recent textbooks it was stated that the lymphocytes in Hodgkin's disease were relatively increased, while in cases of tuberculosis simulating Hodgkin's disease no such increase was present. In the cases of Hodgkin's disease, however, which he had been able to examine, no such relative lymphocytosis had been seen. He wished to know if Dr. Dow had noticed this point in his case.

Dr. Dow replied that he had not noticed any such change.

Dr. Field remarked that, in view of the recent discoveries in regard to the pathology of Hodgkin's disease, it was important that all such cases should be put through a careful examination for tubercle bacilli.

Dr. Ewing said that he would like to add, not only for the tubercle bacilli, but for other bacteria as well.

Dr. Dow said there was no evidence of tubercle bacilli in the tonsils or in the lymph nodes. He would like some expression of opinion from the members of the society as to whether the ulceration of the tonsils was a primary condition, or whether it was secondary to the hyperplasia. If secondary, why should it occur in the tissues of the tonsils rather than in the hyperplastic lymph nodes?

Multiple Embolisms of Mesenteric Arteries.—Dr. Philips reported this case. The subject of it was a physician, thirty-three years of age, who had always been healthy and who had never had venereal disease or gout. He gave a vague history of attacks of pain, five years before, in the right inguinal region, lasting two or three days. The patient was quite alcoholic, drinking beer and whiskey, and an immoderate eater. For three or four nights before the onset of the present trouble he had been intoxicated. He had awakened in the morning about 4 o'clock complaining of severe abdominal pain, which was constant and general. He rapidly developed tympanites, and the entire abdomen became generally painful on palpation. There was no localized tumefaction or increased resistance to pressure. He had considerable hiccough and vomited a few times, but there was no blood in the vomitus. It was impossible to get a movement of his bowels by cathartics or high rectal enemas. The pulse rate was between 80 and 90, and he had no fever. During the first twenty-four hours he passed but eight ounces of bloody urine. About forty-eight hours after the onset of the symptoms he was operated upon by Drs. Bull and Coley. The abdominal cavity contained about [illegible] c.c. of serosanguinolent fluid with some flakes of fibrin. The small intestine was much cyanosed and generally distended with gas, and here and there were small hemorrhages under the peritoneum. The omentum was much swollen and contained also many hemorrhagic foci. There was no obstruction of the intestine found. The patient died four hours after the operation, and an autopsy was performed by Dr. Harlow Brooks, who furnished the following notes:

On opening the peritoneal cavity about 300 c.c. of creamy pus escaped and the parietal and visceral layers of the peritoneum were covered with a thin layer of fibrinous pus. The entire gut was distended with gas, particularly the cæcum. The peritoneal capillaries were much injected both on the walls and over the intestines. The omentum was very short and thick and literally studded with small, spherical, injected gangrenous nodules, which appeared not unlike Delaware grapes. Evidently they represented minute embolisms of the omental vessels. The omentum was much walled together, as from previous disease. The mucosa of the stomach showed evidence of chronic gastritis and numerous old healed ulcerations of small size. The appendix was sharply folded on itself and surrounded by œdematous adipose tissue and old adhesions. It was about 2 cm. long, and had evidently ruptured with complete loss of the distal two-thirds. There were no evidences of recent inflammation. The mucosa of the small intestine, as a whole, was much congested, but in places was ischæmic. There were a few minute emboli of the submucous vessels, but more frequent and larger lesions of the same character on the peritoneal surface, resulting in small gangrenous patches. The mesentery of the lower folds of the ileum showed a very marked congestion, with the presence in the small vessels of minute emboli. This condition became more frequent in the upper folds of the mesentery where the emboli were larger. The mesenteric vessels, as a whole, showed the most marked evidence of recent endarteritis, while here and there were portions of the intima which were calcified. The pancreas was riddled with fat infiltration. The caliber of the artery was about that of the auxiliary, with enormously thickened intima. The pancreatic duct was gangrenous in part, apparently from thrombosis of its nutrient artery. There was extensive infiltration of the pancreatic interstitium, apparently inflammatory. The liver was moderately fatty and considerably congested. The kidneys showed evidences of acute nephritis, with very evident fatty degeneration. The heart was large, and the muscle showed extensive fatty degeneration. The valves were thin but competent. In the right auricle was a preformed clot, evidently of two or three days' duration. It was distinctly laminated, very firm, and on the surface was covered with small granulomatous masses. It was firmly adherent to the superior external wall of the auricle and showed beginning organization. The coronary muscles were much thickened and atheromatous. The aorta was of small caliber but atheromatous throughout. The lungs were congested and showed here and there small recent hemorrhagic infarctions. The cause of death was multiple infarction of the pulmonary and mesenteric vessels from thrombosis of the right auricle, a condition occurring in acute alcoholic toxæmia.

In reply to questions, Dr. Philips said that no cultures had been taken. There had been no symptoms of bacterial infection of any kind during life, nor did the autopsy suggest this as the probable cause of death.

The Significance of Intramedullary Degenerations.—Dr. M. G. Schlapp read a paper on this subject. He said that, at a recent meeting of this society, he had presented sections through the spinal cord, medulla, pons and the region of the nucleus of the third nerve, in a case of tumor of the right hemisphere of the cerebellum. These sections had been presented in order to show degenerations in the posterior columns, which had been described by other writers, and similar degenerations in the intramedullary fibers of the sensory cranial nerves, while the latter had not, to his knowledge, been described before.

The specimens now to be presented were in addition to the aforesaid sections of the cerebellar case: (1) Transverse sections of the spinal cord of a case of crushed cord; (2) sections of a case of transverse myelitis in the cervical region, and (3) sections of a case of alcoholic polyneuritis, in combination with mental disturbances, as described by Korsakow. In the first case the spinal cord was crushed in the region between the sixth and seventh dorsal vertebræ, absolutely destroying the cord in this region. The sections were taken from the lumbar and sacral regions, and showed a marked degeneration of the posterior root-zone of Flechsig. This degeneration could be followed to a point where the posterior root leaves the spinal cord, sometimes a little beyond. This degeneration always stopped, with the exception of a very few fibers, where the sheath of Schwann began. These degenerated fibers were all ascending fibers and short ones, because they soon entered the grey matter, where they seemed to end. In the second case, as in the first, the posterior root-zone was markedly degenerated in the dorsal, lumbar and sacral regions. In the third case the degeneration was also well marked in the posterior root-zone, but was also found in other parts of the spinal cord.

In all these four cases (including the case of cerebellar tumor) a marked lesion was found in the posterior root-zone. In the alcoholic case the nerves were involved; in the cases of transverse lesions of the cord, the descending tracts were all involved below the lesion; in the brain tumor case the degeneration was almost entirely confined to the columns of Burdach, and, especially in the posterior root-zone, a few degenerated fibers in the columns of Goll. The tendon and skin reflexes were missing below the lesion in the cases of transverse lesion of the cord. In the alcoholic case they were missing in the legs and lower part of the body, while in the arms they were very much diminished, and were missing shortly before death. In the brain tumor case they were entirely missing a few weeks before death.

Commenting upon these cases, Dr. Schlapp said that much had been written about the condition of the reflexes in cases of transverse lesion of the spinal cord. Bastian had been the first, he thought, to call attention to the absolute loss of the tendon reflexes of the legs in cases of transverse lesion of the cord in the cervical or upper dorsal regions. His explanation of the loss of the reflexes in the above conditions was that, in a complete lesion of the cord, the fibers which were constantly transmitting a stimulus from the cerebellum to the motor cells in the anterior horns of the spinal cord, whereby the muscles were kept in a normal tonic condition, were cut, and this constant stimulus could not reach the motor cells lying below the lesion; hence, the muscles connected with these cells were not in a normal tonic state, and, consequently, the reflexes which depended upon this tonic state were lost in the muscles involved. Recently cases had been described in which there were absolute transverse lesions of the cord in the cervical and dorsal regions, with reflexes present or exaggerated below the lesion. The case of Kausch was especially important in demonstrating this fact. So the hypothesis of Bastian could not be accepted. The degeneration of the nerve fibers in the posterior root-zone of Flechsig no doubt explained the absence of the reflexes in these cases. In the alcoholic polyneuritis, the changes in the nerves could, in themselves, be sufficient to cause the loss of the reflexes, but the degenerations in the nerves were not so marked as the degenerations in the posterior root-zone of Flechsig. It seemed that the short fibers, entering the cord through the posterior roots, or reflex fibers, were the ones in which the degeneration first took place—in other words, they could not withstand the effects of toxic substances or imperfect circulation as well as the fibers that carry the sensory impressions to the higher centers. This was also supported by clinical observations; that is, the absence of the reflexes was usually the first symptom of a disease in which the posterior columns were affected—*e. g.* tabes dorsalis, ergot poisoning, brain tumor, etc. If the cause producing these degenerations continued long enough, of course, the fibers transmitting the sensory impressions to higher centers would also degenerate, and there would then be a disturbance of sensation.

A Lymphocytozoon of the Guinea-Pig.—Mr. L. B. Goldhorn read this paper. He said that while examining the blood of a certain guinea-pig he had found, in the cytoplasm of a large number of lymphocytes, highly refractile, round or ellipsoid, immotile bodies, which, when stained with ordinary methylene blue, looked like vacuoles. As the nucleus of these cells was considerably displaced and undergoing karyorrhexis, according to the size of the vacuoles, it was suspected that a parasite was present. Upon staining smears with polychrome methylene blue a brilliantly stained body was seen, varying in size from a barely visible dot to more than the size of the nucleus of the lymphocyte. While it frequently filled the space in the lymphocyte completely, it would as frequently appear surrounded by a sharply-defined achromatic zone. This latter appearance was rather constant with the small forms. It was reasoned that if this body was a parasite it might be transmitted by transfusion, and an intravenous injection was made into one young guinea-pig, while a second one received an equal amount of blood intraperitoneally, and a third one had a subcutaneous injection made. One control pig was kept with these young ones, and all were isolated from the old infected pig. The transfused blood was suspended in physiological salt solution. All the animals were first carefully examined for abnormalities in the lymphocytes, with negative results. It was thought best to take young animals because old ones appeared to show the bodies above described in nearly half the number examined. At first blood examinations of the injected pigs were made daily, with entirely negative results. At the expiration of three weeks very diminutive bodies, surrounded by a clear space, were seen in the cytoplasm of the lymphocytes of the pig in which the injection had been made intravenously. The nucleus of such lymphocytes did not show any degenerative change. Three weeks later the size of the parasites had increased to twice the size, but, numerically, they were not increased. At the very best few could be found. The animal on which these observations were made showed as many infected lymphocytes as normal ones. It was a pregnant female, and the two young ones did not show at birth, nor had they shown to this day, lymphocytes containing parasitic bodies. The lymphocytes showed frequently more than one parasite. The only way of telling the small forms from the metachromatically-staining bodies so frequently seen in the cytoplasm of lymphocytes was by observing the clear space surrounding the parasitic bodies. In multiple infection of one cell one parasite was not infrequently observed to be larger than others in the same cell. Two parasites, maturing side by side, were seen from time to time. He had not succeeded in demonstrating anything in the clear space surrounding the very small forms, but it was different with the large ones. In the first place, it was noticed that the latter frequently had a more compact central body. The largest [illegible] would consist of a rounded chromatic body, surrounded by a [illegible], which occupied frequently the entire [illegible] were mentioned. He had come to the conclusion that [illegible] were represented at all times a [illegible] as he had succeeded in finding [illegible] bodies surrounded by a sharply-defined envelope, corresponding [illegible] forms. In other instances [illegible] circulating the blood, discharged their parasites which was found lying free in the plasma, surrounded by a [illegible]. It was probable that Kurloff's cells with vacuoles were those described in the paper, and therefore he would give in full the quotation by Ehrlich, since the original by Kurloff was in Russian. Ehrlich said: "This is surely a peculiar group, characteristic for the blood of the guinea-pig. It shows transitions in the blood from large mononuclears to transitional and polynuclear forms, but is marked by the lack of any kind of granulation. Instead of the latter we find in these cells a roundish nucleus-like form in the protoplasm, which also takes the nuclear stains, and possibly is to be considered an accessory nucleus. We have received the impression that we have here to deal with a vacuole filled with substance secreted by the cell. In a large series of preparations it is possible to obtain some elucidation of the development and fate of these appearances. They first appear in point-like granules in the protoplasm bearing no relation to the cell-nucleus; they gradually increase and acquire a considerable circumference. When they have attained about the size of the cell nucleus they, or rather their contents, appear to break through the protoplasmic membrane and to leave the cell. The number of the vacuole-containing-cells is 15 to 20 per cent. of the colorless blood-corpuscles." Continuing, the speaker said that cells with wide meshes in their cytoplasm, simulating vacuoles, were not infrequently seen in smears, but they were altogether unlike the bodies in question. To regard this body as an accessory nucleus was out of the question. It was seen at times outside of the cell, as already stated, and was then frequently sharply outlined by a more or less achromatic zone. Moreover its affinity for stains was altogether unlike that of the nucleus of the lymphocytes, and it stained best metachromatically. The statement that vacuole-containing cells of the normal guinea-pig number 15 to 20 per cent. of the colorless corpuscles was an error if Kurloff's vacuoles were identical with the bodies described, because there were many guinea-pigs, if not the majority of them, that were free from such bodies. If they were really parasites it might be desirable to examine the blood of guinea-pigs which were to be used for serum reactions to determine if they were heavily infected, as they then might occasionally alter such reactions.

Mr. Goldhorn said that he would be thankful for suggestions on the nature of these bodies. A microscopic examination of the tissues from guinea-pigs, whose lymphocytes contained these bodies, showed that there were in the alveoli of the thyroid gland what appeared to be foreign bodies, sometimes closely resembling encysted parasites, and that between the epithelial cells lining the alveoli smaller foreign bodies were seen. Future investigation would show how constant were these changes. The bone marrow was seen to contain the bodies in lymphocytes in large numbers.

The technique was as follows: "Fix smear in wood alcohol for 15 to 30 seconds; wash in water until water adheres to smear. Stain in polychrome methylene blue (Goldhorn) for a few seconds, or long enough to have the smears look grayish or bluish, and wash thoroughly in clean water. Stain in 1 per cent. eosin for from 15 to 30 seconds, and wash again. Short eosin staining will leave the red corpuscles greenish, while longer eosin staining will give pinkish red corpuscles. Dry in air; mount in balsam."

Dr. [illegible] said he had [illegible] since the specimens were exhibited and had had an opportunity of examining them, but he was unable to [illegible] whether they were parasites or not, though from their appearance he was inclined to think they were.

The Technique of the Determination of the Freezing-Point of Body Fluids by Means of the Beckmann Apparatus.—Dr. F. C. Wood gave this demonstration. The apparatus consists of a thermometer, with a very finely divided scale and two small glass vessels, one of which acts as container for the solution to be tested, the other as an air-jacket to equalize the action of the freezing-mixture in which the vessels and the thermometer are placed. The thermometer can be read to a thousandth of a degree; it is [illegible] and must be adjusted and tested before use by freezing some distilled water, thus ascertaining the zero of the instrument. When the cooling of the fluid is taking place, constant stirring must be done with a small platinum wire, which extends down through one of the corks, closing the inner freezing vessel, which contains the fluid to be tested. The whole apparatus is placed in a large jar, with a mixture of ice and salt containing enough salt to reduce the temperature about one to two degrees below zero Centigrade. This requires only a moderate amount of salt, but the mixture should contain a good deal of water. The whole is wrapped in a thick felt cover to prevent sudden changes of temperature. As the liquid in the freezing chamber cools down the thermometer is noticed to sink gradually below the freezing point of the fluid, and if now rapid stirring be begun, and especially if the stirrer be allowed to strike the bottom of the vessel, small particles of ice will be formed and will be whirled up through the rest of the fluid, at which instant the thermometer will be observed to rise rapidly for a few tenths of a degree, and finally remain constant at a given point, which point cannot be altered by stirring. This is the desired freezing point of the liquid. Dr. Wood said that the rise of temperature was due to the fact that the fluid had become undercooled—that is, had been cooled below its freezing point. When the ice separated, the latent heat of the water was set free and the temperature of the mixture rose, in the case of pure water, to zero, C., and in the case of one of the animal fluids to the freezing point of that fluid. These observations must be repeated three or four times, and the average taken of the readings. They should not vary more than a few thousandths of a degree from each other. The determination of the freezing point of distilled water—in other words, the zero of the instrument—must be made every day, for when the thermometer rose to room temperature the glass of the bulb took a set, which prevented the thermometer returning accurately to zero when it was suddenly cooled. The accurate zero was only reached after the thermometer had been cooled for some time. In making a series of observations it was well to keep the thermometer in an ice-box, so that the zero would not vary, in which case it would not be necessary to adjust the zero every day. The under-cooling should be limited to about three or four-tenths of a degree, and if, as was frequently the case, the fluid refuses to form ice at this temperature, it was necessary to inoculate the mixture by raising the stirrer up to a level with the small side tube, with which the freezing tubes were equipped, and then to touch the stirrer with a small particle of ice or a frozen portion of the substance which was being tested. This caused a small quantity of ice to form on the platinum ring of the stirrer, and when the latter was dropped again into the fluid the formation of ice would immediately begin, and the thermometer would rise to the freezing point desired. The apparatus might be simplified somewhat for clinical purposes, by using, instead of a freezing-mixture of salt and ice, a closed vessel, containing ether, through which, by means of a small water pump, is drawn a current of air. The rapid bubbling of the air causes evaporation of the water and a rapid reduction of the temperature of the freezing vessel containing it. With this apparatus it was often possible to make a determination in ten to fifteen minutes; with the Beckmann apparatus, owing to the large size of the bulb of the thermometer and the necessity for its adjustment, it usually took about two hours for each determination. Time might be saved by using a thermometer with a fixed zero instead of the Beckmann thermometer, in which case the mercury bulb could be made much smaller, but the results obtained were, as a rule, not so accurate as those furnished by the original form of the Beckmann apparatus.

The thermometers should be standardized by comparison with some known instrument, or, what was better, carry a certificate of the Reichs Anstalt that they are accurate.

The importance of the determination of the freezing point of animal fluids was that it gave a physical method of determining, with very considerable exactness, the molecular contents of the fluid, and with it the osmotic pressure which that fluid exerts. The basis of the whole matter had been originally observed by the English physician, Blagden, in 1788. He discovered that the freezing point of a solution was lower than that of the pure solvent, and that this lowering of the freezing point was proportional to the amount of substance contained in solution. This observation remained unused until within the last few years, when, with the development of physical chemistry, it was found that the molecules of a substance dissolved in a fluid acted just as the molecules of a gas act, and that the osmotic pressure, when measured directly, was proportional to the amount of substance dissolved in the fluid, just as the pressure of gas is proportionate to the number of molecules contained in a given volume. These facts were true, without further consideration, when the solution was of a certain nature, such as benzol, but in determining the osmotic pressure of an aqueous fluid, it was found that the proportion between the quantity of substance present and the pressure was not exactly the same. This had led to the further hypothesis, that when substances were dissolved in water they underwent a partial decomposition into ions, and that these ions acted as free and independent molecules, thereby raising the osmotic pressure of the fluid proportionally. This occurred only in dilute solutions, such as were found in the human body. Inasmuch as the direct measurement of osmotic pressure was very time-consuming and very difficult, the freezing point method had found general application in the determination of a number of conditions. It had been found, for example, that, in cases in which the permeability of the kidney was in any way injured—and the best instance of this was a chronic nephritis—the number of molecules in the blood was increased, owing to this inability of the kidney to excrete the molecules into urine. This molecular retention in the blood caused only very slight changes when measured in the ordinary way by specific gravity, but gave a marked increase in the lowering of the freezing point as compared with normal blood. If we took the normal freezing point of the blood as .56°C., the presence of a marked obstruction of the kidney would often lower this point to .60° or .70°C., and thus indicate a retention of molecules in the blood. The method did not give any clue as to the nature of the substance retained, but this might be obtained by chemical analysis. It did, however, give a measure of the amount of substance retained, and as it was fairly easy to obtain, while chemical analysis required days for its results, it had been hoped that this method would afford a rapid and accurate means of diagnosing inefficiency in the excretory power of the kidney. This hope had been partially realized, notably by Koranyi, who had found that not only in experimental nephritis in animals, but in nephritis in human beings, this rise in the molecular contents of the blood could be sufficiently demonstrated. Unfortunately for the practical application of this method, there were many complicating circumstances, the chief one being the fact that cyanosis increases the freezing point of the blood just as does a kidney inefficiency. The method, therefore, did not give true results when cyanosis was present. A great deal of work had been done in the determination of the freezing point of urine, in the hope that this might give a clue to the kidney work, but up to the present no definite conclusions had been reached. Casper and Richter had shown, however, that if the secretions of the kidneys were collected separately by catheterization of the ureter, and then the freezing point of the urine received from each kidney determined, a proportional value would be obtained, which would give the relative capacity of each organ. If then, from the reduction of the freezing point in the blood below 56°C., it was suspected that the kidneys were inefficient, by obtaining the freezing point of the urine from each kidney the efficiency of each could be determined, and in this way it could be ascertained which kidney was diseased, and whether, if one were removed, the other would have sufficient excretory power to handle the products of the bodily metabolism.

An interesting observation of the care necessary to carry out these determinations was shown by the work done by Krönig and Fueth, which had recently been published as a criticism of a paper by Veit. The latter had obtained different results when he determined the freezing point of the mother and of the new-born child, and the difference was such as to represent a pressure difference between the fœtal blood and that of the mother of five pounds to the square inch. It was difficult to understand how so delicate a partition wall as the chorionic membrane could withstand such a pressure, so Krönig and Fueth undertook a re-examination of the entire subject. After a very careful series of observations they showed that the presence of the blood-corpuscles in the fluid to be frozen made no difference in the result. They also determined by a long series of observations the average error of the thermometer used. This error, between two standard instruments, was about nine one-thousandths of a degree. Then, allowing for this error, a series of freezing-point determinations were made with the blood from the mother and the child, and they were found to be the same within the limits of error of the instruments.

NEW YORK ACADEMY OF MEDICINE.

SECTION ON PEDIATRICS.

Stated Meeting, Held May 8, 1902.

R. G. Freeman, M.D., Chairman.

A Case of Acute Leukæmia.—Dr. Sara Welt-Kakels reported this case. She said that to Ebstein belonged the credit of having first clearly defined this disease. She had found on record twenty-four cases of leukæmia, occurring in children under ten years of age. The case now reported was that of a child of eighteen months, first seen last October. The mother had first noticed about one month before that the child was growing very pale, and occasionally some blood or pus was passed from the bowel. On examination the pallor of the skin was very striking. There was no evidence of rachitis. There were numerous purpuric spots all over the body and extremities, varying in size from that of a pin-head to a five-cent piece. The mucous membrane of the mouth was inflamed, the gums were bleeding, and the breath fetid. The post-cervical, axillary and inguinal glands were enlarged. There were soft, blowing systolic murmurs at the base and apex of the heart. The abdomen was very slightly distended. The spleen extended about one inch and a half below the free border of the ribs. The body temperature was 101° F. in the rectum. A drop of blood taken from the ear appeared to the naked ers to be very rare. The proportions of red blood-corpuscles to the white was nearly one to three, and a differential blood count showed 94 per cent. of lymphocytes. The hæmoglobin was very low. There were five times [illegible] lymphocytes to the cubic millimetre, as [illegible]. Usually the large form of lymphocytes predominated, but in that instance the small were three times more numerous than the large. The urine contained some albumin, but no sugar or blood. Dr. Gittings, of the [illegible], and died the same day, or four [illegible] after first [illegible] symptoms. A post-mortem examination was not permitted. The causes of death in these cases were probably asthenia, and hæmorrhage into vital organs. In classifying this disease it should be called, the speaker thought, acute, not so much because of its short duration, but because of the suddenness of its onset and the early occurrence of hæmorrhages, which in chronic leukæmia occur at a far more advanced stage. Hence the importance of the early involvement of the submucous glands. Fussell was of the opinion that the mouth and nose were the favorite portals of infection. The prognosis of acute leukæmia was absolutely fatal, death resulting either from sepsis following secondary infection, from asthenia following great loss of blood, or from coma arising from hæmorrhage into the brain or meninges.

Dr. Charles Herrman said that in a recently published case of acute leukæmia in a child an enormous thymus gland had been found. There were certain things about this affection which reminded one of the constitutio lymphatica.

Summer Diarrhœa of Infancy.—This was the general subject for the evening's discussion.

Etiology and Prophylaxis.—Dr. Henry Heiman opened the discussion with this paper. He said that the term summer diarrhœa was plainly a misnomer in the light of our present knowledge of this affection. All evidence pointed to the inseparable relation between bacteria and summer diarrhœa. So positive was this evidence that it was now acknowledged that several intestinal micro-organisms might become virulent under special conditions. It should not be forgotten that there existed in the intestinal tract certain bacteria which performed physiological instead of a pathological function, their office being to split up certain substances and so aid digestion. It was known that among certain intestinal bacteria there was an antagonistic action, and this explained the presence of large numbers and different kinds of bacteria without any pathological consequences. A fairly good classification of the diarrhœas under discussion was into infectious and non-infectious, the first variety being subdivided into inflammatory and non-inflammatory. That heat, and especially humidity, was largely responsible for the diarrhœas in children, was beyond doubt. These meteorological conditions favored intestinal putrefaction. By far the most frequent exciting cause of these diarrhœas was faulty feeding. In his dispensary practice he had noted that summer diarrhœa was becoming less frequent each year, and this he attributed to increased knowledge as to the best methods of infant feeding. In children fed on a mixed diet the use of unripe or decayed fruit was a very common cause of diarrhœa. The aim of the physician should be to secure pure milk for bottle-fed children. The great menace from both bottle and breast feeding lay in over-feeding. A good prophylaxis during hot weather was to diminish the quantity of food, substituting boiled water and a cereal for some of the proteids and fats. Prophylaxis should extend beyond the work of the physician, and should consist in securing by legislation properly built tenement houses and providing parks and other breathing spaces for children who cannot leave the hot cities.

Renal Complications.—Dr. J. Lovett Morse of Boston read this paper. He said that thrombosis of the renal veins with hemorrhage had been found not very infrequently, and degenerative lesions of a granular type were acute nephritis. The tubules contained casts of various sorts and sometimes blood. Similar though less marked changes were found in Henle's loops and in the straight tubes. Fatty degeneration was unusual and occurred only in the chronic form. Glomerular changes were rare. Microorganisms were usually not present. In other words, the alterations in the kidneys in the acute diarrhœas of children were mainly degenerative in type, without anything characteristic, and were similar in every way to those found in other diseases, both in children and in adults. Most observers attributed these changes to the absorption of toxic substances from the intestines. It was probable that other factors than the bacteria played a part in these renal alterations. The quantity of the urine was more or less diminished, in part due to the dehydration from the diarrhœa and the diminished ingestion of liquids. Albuminuria was usually present but not in large amount. Degenerated epithelial cells were numerous, but blood was uncommon. There was an excess of uric acid or urates. Similar changes were observed in cases that recovered. This class of cases was best described as acute degenerative nephritis.

In his own cases no relation could be determined between the presence of albumin in the urine and the symptoms present. Koplik claimed that the chief symptoms of this affection were persistent vomiting, restlessness, and œdema of the face, legs and feet. He said that he had only met with one autopsy in which the nephritis had been sufficiently marked to have taken direct part in the fatal result. This nephritis, he thought, should be regarded in a general way as an indication of toxæmia. Acute pyelitis and pyelonephritis might occur as complications of acute enteric disease. They were usually mild in type, and were almost always the result of infection with the colon bacillus. They had practically no effect on the prognosis. The treatment of renal complications consisted in removing the irritation of the kidneys and endeavoring to remove the primary disease.

Treatment.—Dr. Charles G. Kerley read this paper. It should be remembered, he said, that primarily the intestinal contents were involved, and not the intestine itself. Realizing that the physician had a poisoned child to treat, the indications were clear. Every case, whether mild or severe, should be given castor oil or calomel, the former being preferred. Regardless of the source of the milk, it must be stopped at once, for the reason that it furnishes an exceedingly favorable culture medium for bacteria. It did not do the slightest good to dilute the milk, or to pasteurize or sterilize, indeed, heating the milk distinctly aggravated the condition. A substitute diet was, of course, to be selected, and a carbohydrate diet had given him the best results. Children tire of this, and hence it was well to change the taste by adding small quantities of beef juice or chicken broth, well salted. These must be used sparingly, however, as they often give rise to infantile diarrhœa. The free use of brandy or whiskey, as practised by many, seemed to him a mistake, as it tended to destroy the feeble powers of digestion and tended to irritate the kidneys. He had used egg albumen water freely, but had abandoned it because he had found that many sick infants did not well digest it. The diet of fever patients should contain a liberal supply of carbohydrate, and in summer diarrhœa there is usually a good deal of fever. The substitute carbohydrate diet should be given at intervals of two hours, and in such quantity as milk had been given previously. Boiled water should be given freely at any time. The child should be kept in a large airy room, and the milk diet should not be resumed until the fever had gone and the stools had become normal, and the return to milk diet should be effected very gradually. One drug seemed to him of special value in these cases, and that was the subnitrate of bismuth, given in large doses, ten to twenty grains every hour or two. There was no use in giving this remedy except in sufficient quantity to cause black stools. Opium was also useful, but must be employed with great caution. It should never be given unless there were more than four or five stools a day, for this number was necessary for proper drainage. He preferred Dover's powder, one-quarter to one-half a grain every three or four hours for a child of one year old. For heart stimulation, strychnine and strophanthus were preferable. Irrigation of the colon was of much service where the stools contained much mucus and blood, but for other cases irrigation accomplished little but an increase of the irritation of the rectum. Ordinarily, not more than two irrigations should be given in the twenty-four hours, and normal salt solution should be used. For the purpose of irrigation he made use of an ordinary rectal tube, No. 17 of the American scale. The tube should be introduced nine inches, and the reservoir should not be more than three feet above the child's body. Ordinarily, the fluid should be lukewarm, but when the temperature of the body was very high the use of water at 70° F. would help to reduce the body temperature. In cases on the verge of collapse, the use of very hot saline solution acted as a valuable stimulant.

Dr. William L. Stowell said that he had never found it necessary to pay special attention to the occurrence of renal complications in connection with summer diarrhœa. On going over the statistics of the Demilt Dispensary for the past three years and a half, he had been surprised at the small number of deaths from summer diarrhœa. He had been in the habit of using antiseptics in these cases, especially salol, and also of using intestinal irrigation, not only to remove irritating substances, but because of the effect on the child obtained by varying the temperature of the saline solution. He had tried a great many remedies, and was inclined to believe that too much attention should not be given to the fine selection of remedies—in other words, the drug treatment was a very subordinate part. He was positive that there was much less summer diarrhœa now than a few years ago, and the cases were of a milder type. This he attributed to a better understanding of the subject of infant feeding.

Dr. B. Van Doren Hedges of Plainfield, N. J., said his attention had been called to the bad effect of chronic over-distention of the stomach. The habit of giving infants quantities of food entirely too large for the size of the stomach tended to weaken the muscular walls, and in this way predisposed to disease. Dr. Kerley had preached the true and only gospel as to the treatment of summer diarrhœa. Personally, he had always been very chary about giving opium in the acute stage of the disease unless the case could be very carefully watched. The administration of opium would often reduce the number of the stools, but unless this was associated with an improvement in their character the opium was doing harm. It was also important to insist that the stools should be saved for the physician to inspect. He had found bismuth particulary soothing and beneficial.

Dr. Walter Lester Carr said that he had noted in some cases of diarrhœa complicated by renal disease a very rapid pulse, an unusual amount of dyspnœa and persistent vomiting. He had usually found œdema wanting, except in protracted or intermittent cases. He had been surprised at the very small quantity of albumin present in the urine of these children. Quite possible it was because of this and the mildness of the affection that it was often overlooked altogether. At one time he had experimented quite extensively with salol, and had obtained good results, but in later years he had practically abandoned the use of all intestinal antiseptics, and felt that the children did just as well by employing the general principles so well outlined by Dr. Kerley.

Dr. L. E. La Fetra said that a rather rare type of summer diarrhœa, not yet referred to, was that in which the intoxication of the intestine was a local instead of a general one. In these cases, instead of there being diarrhœa, there was really constipation, associated with fever and symptoms of intoxication. It had been his misfortune to have had one such case, which had gone to a fatal issue. The case emphasized the importance of maintaining intestinal drainage and the need for the physician to imitate nature's methods. In such cases a saline cathartic would be found especially useful.

Dr. E. Libman said that he had usually found a parenchymatous degeneration of the kidneys, such as had been described by Dr. Morse. He did not recall having found a typical acute nephritis in connection with infantile diarrhœa. The very fact that there was diarrhœa allowed of the elimination of the toxins. It was probable that by the older methods of treatment, the use of opium and astringents, the eliminaton of the toxins being interfered with, the effect on the kidney was more marked. The speaker deplored the tendency to ignore scientific classification of these cases, and being content to speak of them by the very general term of summer diarrhœa. The streptococcus cases could be readily separated, and they should be, for these children sometimes die from systemic infection. The pyocyaneus cases also could be easily diagnosticated and separated. He did not, however, mean to say that the treatment of these different divisions was different.

Dr. J. Finley Bell of Englewood, N. J., said that in 1899 and 1900 he had seen in the village of Easthampton, Long Island, many cases of diarrhœa during August and September, characterized by a very high temperature, convulsions and vomiting. Bacteriological examination of the stools showed most of these cases to be streptococcus diarrhœas. In looking for the cause, it was found that as soon as milk diet was resumed relapse was much more frequent than was usual. Inspection of the herds supplying most of the milk to the village showed that three out of eight of the cows had an eruption on the teats and udders. A culture from one of the pustules showed staphylococci and streptococci. Dr. E. F. Brush saw the animals and asserted that they were suffering from cow-pox. Further investigation showed that three out of four of the herds supplying the village were similarly diseased. The animals were quarantined and the epidemic of diarrhœa ceased almost immediately. For several years previously the summer diarrhœas had been very prevalent and exceedingly fatal in the neighboring town of Sag Harbor, and one of the physicians practising there stated that these diarrhœas were of the streptococcus variety. This led to an investigation of the milk supply, with the result that the animals were found to be infected with streptococci.

Dr. W. L. Baner commended very highly the paper of Dr. Kerley, which, he was sure, would be the means of popularizing the very rational treatment of summer diarrhœa there detailed. He would be inclined to substitute for the bismuth the administration of sulphate of sodium in doses of fifteen grains every three or four hours to a child one year old.

Dr. J. J. Walsh said that a good many of the coal-tar products were used rather freely with the idea of counteracting the germs in the intestine. Even the administration of small doses of salol to these sick children was pretty sure to do harm. It was very probable that the skin and the intestine occupied correlative positions as regards the blood supply, and this explained the effect of changes of temperature in producing diarrhœa, whether the change was from hot to cold or *vice versa*. To avoid sudden changes of temperature, children should be given two or three baths on very hot days, or should be allowed to play for a considerable time in the bath. This was one of the best prophylactic measures against diarrhœa during very hot weather.

Dr. H. Heiman remarked that a great point in the [illegible] was [illegible] to these [illegible] in the [illegible].

Dr. Morse thought it was far better to speak of the whole [illegible] diseases of infancy than [illegible] diarrhœa. These affections could be roughly divided into three classes, viz.: (1) A class in which there were merely increased peristalsis or simple diarrhœa; (2) Those in which there were organic changes; and (3) A class in which there might or might not be organic changes. The last class constituted the great bulk of the cases. He firmly believed that it was necessary to withdraw milk for a time, though perhaps not so long as Dr. Kerley thought necessary. He believed [illegible] was contra-indicated and that [illegible] was the most useful drug. He would only give opium in those cases in which the peristalsis appeared to be unduly increased. In this same class the astringents were indicated, the best of these being tannigen and tannalbin. He felt that irrigation of the bowel had been overdone, and that it was only indicated in a comparatively small class. The subcutaneous injection of salt solution was most useful in the very severe cases of infantile diarrhœa.

Dr. Kerley said that salol was not beneficial, and as it almost surely disturbed the stomach it should be avoided. He had seen the case referred to by Dr. La Fetra, and had been greatly interested in it. There had apparently been a paralysis of the bowel, and it certainly refused to yield to treatment.

Dr. R. G. Freeman said that while bismuth was apparently very successful in private practice, none of the physicians at the New York Foundling Hospital had been impressed with its value in infantile diarrhœas. More recently they had been using there two or three drops of castor oil with each dose of bismuth, and the result had apparently been much better. Reference was made to the advantage of having small wards in children's hospitals, so that the little sufferers would not be disturbed by the crying of the others.

The Biological Chemistry of Egg Albumen.—F. Obermayer and E. P. Pick have studied the precipitin-producing properties of the various chemical constituents of egg albumen when such are inoculated into various animals. They show that the formation of precipitins produced by immunization with the various albuminoids of egg albumen, is not directly dependent upon the variety of the albuminoid thus used, but is produced by a substance which can only be separated with great difficulty from such albuminoids. This formation of precipitins is not, therefore, specific in so far as the different albuminoids are concerned. The precipitinogen (immunizing substance) and the egg albumen precipitins are not albuminoids. The egg albumen precipitin is not destroyed by heating in neutral or acid solutions or by trypsin-digestion in alkaline solutions. Pepsin-digestion destroys the action of precipitinogen and egg albumen precipitin. From the above it is apparent that the "biological reactions" is of no value in the identification of the various albuminoids.—*Wiener klinische Rundschau.*

THE RÔLE OF INHIBITION IN THE NORMAL AND IN SOME OF THE PATHOLOGICAL PHENOMENA OF LIFE.*

By S. J. MELTZER, M.D.,
NEW YORK.

Introductory.—Three years ago I read a paper on "Inhibition" before the Academy of Medicine, in which I gave an account of our knowledge of this phenomenon as met with in animal life. The great number of facts I presented there led up to the brief conclusion that inhibition is present in and essential to each and every mechanism of animal life. As disease is a disturbance of some or many life mechanisms, we may well expect to find that inhibition is also an essential factor in many forms of disease. As a matter of fact, however, pathology has not even as much as taken serious notice of this biological phenomenon. Except, perhaps, for an occasional reference to the well-known effect of the vagus upon the heart, inhibition is not even mentioned in many leading textbooks on pathology.

With the conviction that inhibition is a fundamental factor in the phenomena of normal and abnormal life, I again come forward to do missionary work for the recognition of this much-neglected and little understood life-force. The chief aim of my paper to-night is to discuss inhibition in its relation to some forms of disease. This, however, will have to be preceded by a discussion of the place inhibition occupies in the functions of normal life, a discussion which, I believe, is not made superfluous by my previous paper on the same subject.

I shall begin with a brief review of the functions, organs, tissues, etc., in which the presence of inhibition has been firmly established.

THE RÔLE OF INHIBITION IN NORMAL LIFE.

Cardiac Inhibition.—The perceptible manifestations of animal life imply motion, secretion, or sensation. Of these the motor phenomena are the most striking, and the best studied. So inhibition, too, is best studied in functions and organs of the animal body, in which active motion is an essential and visible factor. We shall discuss first and more extensively motor inhibition, beginning with the peripheral organs. Here we meet, in the first place, the inhibitory effect of the vagus upon the heart, the discovery of which, as is well known, opened up the entire subject of inhibition, and which still represents its most instructive example. Stimulation of the peripheral end of the vagus causes the following effects upon the heart: (1) It diminishes the number of beats, or abolishes them entirely; (2) It diminishes the height and the force of the contraction; (3) It decreases or abolishes the tonus of the cardiac muscle; normally, the heart even in diastole is not entirely relaxed; it has a tonus; stimulation of the vagus inhibits this tonus; (4) It diminishes the excitability of the heart muscle; during an efficient excitation of the vagus, direct stimulation of the heart muscle causes no contraction; (5) According to Gaskell, stimulation of the vagus abolishes also the conductivity of the heart muscle. The last two effects are most remarkable. Excitability and conductivity are the most fundamental properties of living tissue, yet we see them here abolished through the stimulation of a nerve; (6) Finally, we have to note the discovery of Gaskell, that the heart muscle shows a "positive variation" of the electric current during the vagus stimulation—that is, the direction of the current is opposite to that which takes place when a muscle contracts.

It is of great interest to know that the accelerator or augmentor nerve shows effects upon the heart exactly opposite to those of the vagus. Stimulation of the accelerators causes: (1) An increase in the number of heart beats; (2) An increase in their height and force; (3) An increase of the tonus of the heart; (4) An increase of the excitability of the heart muscle; (5) An increase of its conductivity, and (6) causes a negative variation of the muscle current.

Accordingly, the heart muscle stands under the control of two antagonistic agencies; one increasing its motor manifestations, the other inhibiting them.

Vascular Inhibition.—Similar conditions prevail in the vascular system. All the small arteries of the body (including, probably, also those of the lungs and the brain), stand under the control of the vasoconstrictors and vasodilators. The vasodilatation is accomplished through the inhibition of the tonus of the circular muscle-fibers of the blood-vessels. Vasodilators are to the blood vessels what the vagi are to the heart—they are inhibitors. Generally both kinds of nerve-fibers are present in one and the same nerve-trunk, and for reasons which we shall discuss later, artificial stimulation of such a nerve brings out, chiefly, constriction. A number of methods have been developed, however, by means of which the presence of vasoinhibitors has been demonstrated for nearly every region of the body. The special characteristics of the vasodilators are, of course, studied best when they are found in a nerve-trunk alone or, at least, with very little admixture of their antagonist. The chorda tympani, for instance, represents such a nerve. The extensive studies of the vasomotor mechanism have demonstrated that the motor conditions of the blood vessels are at all times, and in any region of the body, a resultant of the two antagonistic agencies—the vasoconstrictors and vasoinhibitors.

Inhibition in the Alimentary Tract.—Regarding the movements in the alimentary tract, we can now state that the entire canal stands under the control of motor and inhibitory agencies. The inhibitory effect of the splanchnic nerves upon the intestines has been known for more than forty years

Within the last two or three decades the motor conditions of the alimentary canal have been studied by many investigators and it can be consid-

*Read before the New York Academy of Medicine, February 6, 1902.

ered as settled that every section of the tract is provided with inhibitory mechanisms. With every act of deglutition a wave of inhibition sweeps over the œsophagus running ahead of the peristaltic movement (Kronecker and Meltzer). A bolus introduced in the lumen of the intestinal canal causes a constriction above and an inhibition below the bolus (Bayliss and Starling). The more or less strong tonic contraction of the cardia, the pylorus and the anal sphincters, the different forms of the movements of the stomach, of the small and large intestines and the moderate tonicity of the walls of the gastro-intestinal canal when at rest, all are under the conjoined management of the motor and inhibitory nerve fibers contained partly in the vagi, partly in nerves emanating from the thoraco-abdominal sympathetic.

I shall not speak in detail of the inhibition in the bladder, the iris, etc. I shall only state briefly that inhibition was discovered to be present in nearly all organs which have some degree of motion due to the presence of smooth muscle fibers.

Inhibition in Striated Muscles.—The organs we have spoken of so far have this in common that the movements are accomplished, as was just mentioned, by smooth muscle fibers, however the heart already presents to a certain extent an intermediary form between smooth muscle tissue and striated muscles. Regarding the manifestations of inhibition in the latter the facts at hand are not yet numerous. Inhibition was found to be present in the retractor penis muscle of the dog and hedgehog, which consists of striated fibers, and contains no nerve cells, but contracts only involuntarily. A beautiful example of inhibition was found in the crayfish, in the motor nerves of the muscles of its claws. We shall have occasion to mention it later. It is, however, quite difficult to prove the existence of inhibition in the skeletal muscles of the vertebrates, as there is no tonicity in the nerve-muscle preparation, and apparently each effective stimulus brings out only a contraction. There are, however, already a number of experiments on record which show unmistakably the presence of inhibitory fibers in the motor nerve. I shall quote one experiment as an illustration: A tetanus is brought on in the muscle of a nerve muscle preparation if the central end of the nerve becomes dry. When the tetanus has passed off no stimulus applied to the intact part of the nerve or to the muscle itself can bring out a contraction. Stimulation, however, of the muscle as well as the nerve is immediately effective as soon as the dried end is cut off. The drying of the nerve end apparently exerts an inhibition upon the nerve-muscle preparation, which cannot be overcome by any stimulation of another part of the nerve or the muscle. The number of physiologists who declare themselves in favor of the theory that the skeletal muscles are provided with inhibitory nerve-fibers is, indeed, continually increasing. Most of them, however, seem to look at the end-plates of the motor nerve as the place where the inhibition takes place. The experiment just mentioned, however, seems to me to demonstrate that the inhibition can take place also in the muscle tissue itself, because if the inhibition due to drying of the central nerve-end would affect only the motor impulse in the end-plate of the nerve, there would be no reason why the muscle substance itself should not respond to a stimulation just as a muscle, the end-plates of which are poisoned by curare, responds to a local stimulus. As yet, however, the question of existence of inhibition in the muscle substance has hardly been seriously studied by anyone. So far as I know, there is only one experiment which concerns itself with this question—it is as follows: A veratrinized muscle shows a very slow relaxation after a contraction. If during this slow relaxation a stimulus is applied to the muscle, the relaxation is rapidly finished, which means, according to Biedermann, that the tonicity of the muscle, due to the effect of veratrin, is inhibited by the applied stimulus. Now the same phenomenon occurs also in a curarized muscle, which fact Piotrkowski considers as a proof that inhibition takes place also in the muscle substance itself.

From the foregoing we can safely draw the conclusion that all peripheral organs which are endowed with some form of motion are also endowed with agencies inhibiting this motion. We shall now proceed to examine briefly the presence of inhibition in the central organs.

Inhibition of Respiration.—When the central end of the laryngeal superior nerve is stimulated with a moderate electrical current, or any other form of stimulus, the respiration stands still. The same can be accomplished, although less promptly, by stimulation of the second branch of the trigeminus or the central end of the splanchnic nerve.

The respiratory standstill in these cases means simply a cessation of the rhythmic contraction of the inspiratory muscles—an inhibition of inspiration. As the cause of the inspiration is located in the center of respiration in the medulla oblongata, no matter whether this cause is of automatic or of reflex origin, the inhibition accordingly takes place within the respiratory center. In other words, this effect of the laryngeal superior nerve is a clear example of central inhibition.

Another example of central inhibition is the prompt and uniform effect of the depressor nerve. There is in the medulla oblongata a center which keeps all the blood vessels of the body at a certain degree of constriction. When the central end of the nervus depressor is stimulated the blood pressure falls considerably; the tonus of the center is depressed—is inhibited.

Inhibition of Reflexes.—There are a great number of instances of inhibition of general reflexes. I shall not enter into a detailed description of these phenomena, but shall summarize them in the following general statement: If any part of the body manifests tonic or clonic, rhythmic or irregular contractions of central origin, be they brought about by peripheral stimuli applied to the cortex, or by anæsthesia or by removal or division of certain parts of the central nervous system; these reflex contractions can often be diminished or entirely inhibited by stimulation of certain other parts of the body, and sometimes even of the same region or contracting parts. Anybody who is familiar with these special studies will find that this statement covers about all the facts known in this line of investigation. At present nobody seems to doubt any longer that this abolition of the reflex contraction means inhibition which takes place within the central nervous system.

I would like to call to mind here the distinction which is to be made between inhibition of reflexes and reflex inhibition. In the latter case the inhibition takes place in a peripheral organ, while the process in the central organ is of the same nature as that of a reflex motion except that the centrifugal nerve is not a motor but an inhibitory nerve. The well-known strike-reflex (Klopfversuch) illustrates our point. Striking the abdomen of a frog causes an inhibition of the heart beats, which means that the striking of the abdomen sends impulses to the center of the vagus in the medulla oblongata, by means of which the tonus of the cardiac inhibition is increased. The inhibition takes place at the heart, while there is an increase of excitation in the central organ.

On the other hand, the impulses which are sent to the central organ in the cases of inhibition of reflexes cause there a decrease—an inhibition of the existing tonus.

An instructive illustration of central inhibition is to be found in the fact that the inhibition involved in each act of swallowing spreads rapidly from the center of deglutition not only to neighboring centers within the medulla oblongata, but also to distant centers in the lower part of the medulla spinalis.

The process which depresses or inhibits any tonic state within the central nervous system has to occur in the same elements in which the tonic state or reflex activity takes place, and that is, according to the prevailing view, in the nerve cells.

In other words, inhibition in the central organ means inhibition in the nerve cells. Now the character of the excitation in a nerve cell, even if it is the immediate cause of motion, has certainly nothing in common with motion as such, and is therefore simply excitation.

Central inhibition means therefore simply inhibition of the excitability within certain groups of nerve cells in the central nervous system.

Inhibition in Nerve Fibers.—This leads us to a consideration of another tissue in which excitability (and conductivity) are practically the only signs of life—I mean the nerve fibers. So far as I know, no experiments have ever been made with a sole view of ascertaining whether nerve fibers are capable of responding to stimulation by inhibition. There is, however, a well-known phenomenon which throws sufficient light on our question—it is the extensively studied phenomenon of electro-tonus. When a galvanic current is applied to a nerve it is found that there is an increase of excitability at the closing of the current around the kathode and at the opening of the current around the anode; and that there is a decrease of excitability and conductivity at the closing of the current around the anode and at the opening around the kathode. This decrease of excitability and conductivity in the nerve, due to stimulation by the anode, can mean nothing else but inhibition. We can therefore state the above in other words: the negative pole causes in the nerve, in the area of its application, excitation at the closing and inhibition at the opening of the current, and the positive pole causes inhibition at the closing and excitation at the opening of the galvanic current.

The excitation of nerve or muscle is accompanied by the appearance of an ingoing electric current—the negative variation. We have seen above that, according to Gaskell, the cardiac inhibition is accompanied by an opposite current—positive variation. The same was observed by Biederman to take place at the inhibition of the muscles of the claws of the crayfish. There are facts in the electrical phenomena involved in the electro-tonus which permit the interpretation that the inhibition in the nerves is also accompanied by the appearance of currents of the positive variety. We shall, however, not enter into a discussion of these intricate problems.

We should recall here that the phenomena of the electro-tonus are observable also in a curarized muscle, which shows us again that the muscle tissue itself is capable of responding to stimulation by inhibition.

We shall now consider briefly the occurrence of inhibition in the other perceptible phenomena of animal life, viz., secretion and sensation.

Inhibition of Secretion.—Secretion depends, to a great extent, upon the blood supply of the secreting gland. And as the supply depends upon the activity of the vasomotors controlling the blood vessels of each gland, when an inhibition of secretion takes place it is obviously difficult to prove that this is due to an inhibition of the process of secretion itself and not only to a decrease in the blood supply of this gland, owing to an increased activity of the local vasoconstrictors. The experimental proof is still more hampered by the fact that in many instances the vasoconstrictors and the inhibitory nerve fibers of secretion are both found to be in the same nerve-trunk, as an artificial stimulation applied to the inhibitory nerves stimulates simultaneously the vasoconstrictors of that gland. Nevertheless, reliable proofs have been brought forward for the presence of purely inhibitory fibers for secretion in many of the body glands. Pawlow and his pupils have established the existence of purely secretory and inhibitory nerve fibers for the secretion of the pancreas. The gastric secretion, too, apparently stands under the control of secretory and inhibitory nerves. Inhibitory effects have been observed upon the secretions of the sweat, lachrymal, milk glands, etc. Although not yet positively proven, it can be safely assumed that the cervical sympathetic nerve contains inhibitory nerve fibers for the secretion of the submaxillary gland. It is an interesting and instructive fact that the stimulation of the sympathetic is accompanied by a positive variation of the electric current in the submaxillary gland, a phenomenon which, as stated above, was found to accompany inhibition in muscles.

Inhibition of Sensation.—As to the experimental studies of the rôle of inhibition in the mechanism of sensation there is as yet not very much to report. For obvious reasons it is confined to observations made on human beings. Occasional observations have been made that the application of one stimulus diminishes the intensity of a sensation produced by another stimulus. Biting the teeth to stand a pain, scratching to relieve itching, hitting one part of the body to diminish a pain in the same or another part, and many similar instances probably belong to the chapter of inhibition of sensation. Recently the subject was studied methodically by Haymans. He states that stimuli of the same kind applied to different localities or stimuli of a different kind applied even to the same place inhibit one another according to certain proportions found by him in his extensive painstaking experiments. However, this part of psychology and physiology of the senses is still in its infancy, and I shall not discuss it here any further. I shall only say that the excitability and conductivity of nerve-fibers and nerve-cells which serve as elements for sensation are probably just as much subjected to inhibitory influences as are the excitability and conductivity of the nerves and cells which serve as elements, for instance, in reflex actions.

The Relations of Inhibition to Irritability.—The foregoing review of the facts concerning inhibition demonstrates conclusively the omnipresence of this phenomenon in the animal body. It is present in the phenomena of motion, secretion, and sensation; it is present in peripheral and central organs; it is present in nerve-cells, nerve-fibers, and in smooth and striated muscle tissue. It can be definitely stated that from all parts of the body from which by stimulation a certain vital activity can be brought out, an inhibition of this activity can also be brought out by stimulation. Later we shall discuss what conditions it depends on whether a stimulation is responded to by an excitation or by an inhibition.

Since Haller we speak of irritability as the chief characteristic of living tissues, and we understand by irritability the capacity of the tissue to respond to stimulation with one of the vital reactions. We formerly knew only one kind of reaction, and that was the activity of the vital tissues; therefore irritability, excitability and the specific activity of the tissues were all used synonymously. We know now that all irritable tissues can respond also with an inhibition of an existing vital activity. Inhibition, then too, has the same extent as irritability. But, as inhibition and excitation are antagonistic phenomena, excitation certainly cannot be synonymous with irritability. These and other considerations lead me to formulate the following general biological law of irritability:

All living tissues are irritable, i.e., they respond to stimulation with a vital reaction. This reaction can be either the manifestations of their specific activity, and we shall henceforth term it excitation, or it can be an inhibition of an existing activity.

Rest a Function of Inhibition.—Hand in hand with the dominating conception that activity is the sole expression of irritability, and therefore the sole sign of life, goes implicitly the opinion that rest of a function is no vital part of it. A muscle, for instance, according to the current conception, is at rest because it is not stimulated. Rest is a sort of temporary death without stimulation and without any vital reaction. This view is derived from the every-day conception of the nature of rest in the physical world. A body does not move, it is believed, because there is no cause for such motion. However, even here it is an erroneous conception. What appears to the common mind as rest is, in reality, a resultant of two exactly adjusted opposing energies. The rest of the rock is simply a resultant of the gravity of masses of the rock, exactly opposed by the cohesive power of the masses under it. When both opposing energies are exactly even then the result is absolute rest. When there is a difference then there is a motion which is proportionate to this difference. This applies also to the antagonistic energies of excitation and inhibition. I claim that during the life of the normal animal rest is just such a vital manifestation as activity;* the difference between activity and rest consists only in the fact that excitation predominates during activity and inhibition predominates during rest. Between these two extremes there is a great variety of intermediary states, but they are all only resultants of the two antagonistic vital energies. All the living tissues are continually subjected to the effects of stimulation, which is continually going on in the living body. Certain conditions and mechanisms, which we shall speak of later, determine which of the forces and to what extent it shall respond to each stimulation. In other words, during the normal life of the animal each living tissue is continually stimulated; each and every phase of life is a vital process, and each and every state is a resultant of the two components of life.

As to the agents which keep up this continual stimulation of the living tissues, there is no lack of them around the body and within it—the continual stimulations of the senses by the changes in the surrounding atmospheric air, its temperature, pressure, and humidity, the stimulations of sound, light, the ever-present mechanical vibrations and other external factors, then the chemical changes within the tissues, the chemical and mechanical processes in the digestive canal, the electrical currents of the active organs, etc. I have repeatedly insisted in former papers on the value of the heart-beat as a mechanical stimulus to all parts of the body. Furthermore, we have to keep in mind that our knowledge of the value of the stimulus and its limitations is derived from laboratory experimentations, and that, however, nature can and does make extensive use also of such stimuli which in the artificial laboratory methods would be considered as subliminal and ineffective.

The Restricted Function of Irritability.—The views which I advocate here are in the main in accord with the theories of Hering, Gaskell, Biedermann and a few other physiologists. Hering and Gaskell, however, assumed further that excitation is identical with dissimilation or catabolism and inhibition is identical with assimilation or anabolism; that, for instance, the accelerator nerves control the catabolic processes and the vagi control the anabolic processes of the heart muscle. While it is, indeed, true that for instance with each contraction of the muscle some of its stored up material becomes transformed, dissimilated, and by inhibition of a contraction some of the material is saved, and the muscle therefore gains by rest, we have no reason, it seems to me, to go so far as to assume that inhibition is directly implicated in the process of anabolism and still less that the inhibitory nerves control the entire process of anabolism. Neither is it absolutely necessary to assume that excitation of the muscle has anything to do with its contraction as such, or with the dissimilation of the material, and still less have we reason to claim that the motor nerves control the entire catabolism which, in all probability, takes place continually within the muscle. It seems to me that the great number of facts we know regarding excitation and inhibition of living tissues possessing different specific activities can be more satisfactorily explained by the assumption that excitation and inhibition concern themselves neither with the creation of the specific material of each tissue nor with the specific forms of the expenditures, but that the point of attack of the two components of irritability, which is common to all living tissues, is solely the mechanism of the conversion of the potential into kinetic energy. To illustrate this conception of the mechanism of irritability, I should compare it to a stop-cock in a tube coming from a reservoir which contains, let us say, illuminating gas.

When the stop-cock is so turned as to permit the gas to escape and the gas is lit, the reservoir loses gas which is burned up, dissimilated. But the turning of the stop-cock has nothing to do with the burning up, with the dissimilation, of the gas. Neither does the turning back, the closing of the stop-cock, which stops the escape of the gas, have anything to do with the generation of the gas. The excitation caused by stimulation of the motor-nerve opens the stop-cock, it permits or facilitates the conversion of the potential energy into such kinetic energy which is specific to that organ, and that is contraction; inhibition turns back the stop-cock; it prevents the conversion, thus economizing the consumption of the potential energy of the muscle. But neither does the excitation have anything to do with the nature of the kinetic energy, nor does the inhibition have anything to do with the creation of the potential energy of the muscle. The tube bearing the stop-cock may be connected with a reservoir containing other materials than illuminating gas, the contents might be, for instance, steam, chloroform vapor or some other substances. The opening of the stop-cock in these cases might be the indirect means of producing heat or motion or anæsthesia or anything else. In all of these different cases the mechanism of the stop-cock might be exactly the same, but in none of them does the opening or closing of the stop-cock have anything to do with the generation of the materials within the reservoir, nor with the effects of these materials when permitted to escape through the tube. So the processes of the potential energies in the muscles, the glands, the nerve cells, or the nerve fibers are, probably, in each case of a different character. Of the kinetic energies of these tissues we know that they are of a different nature; it is contractility for the muscles, secretion for the gland cells, sensation for some of the nerve-cells and, possibly, conductivity for the nerve-fibers. The nature of the irritability, however, remains in all these different tissues the same, the excitation facilitates the conversion of the potential into the kinetic energy, and inhibition hinders this conversion. We have for the present no means of recognizing excitation or inhibition except indirectly, *i. e.* by the effects of the activities of the tissues, by the appearance or disappearance of the specific kinetic energies; hence the confusion of irritability with its effects.* (Possibly the appearance of the ingoing or outgoing electric currents —negative and positive variation—is, indeed, a phenomenon accompanying directly excitation and inhibition. It occurs in the same manner as the different activities of the different tissues. This theory would also explain the fact that when a muscle is stimulated the current appears at the beginning of the latent period and not coincident with the onset of the contraction.)

---

*I do not, of course, speak here of such conditions of rest as paralysis, atrophy, etc.; they are due to some loss of vitality and do not belong to normal life.

The view which I have presented here does not preclude the possibility of the existence of trophic nerves. If they do exist, they too, as all nerves for other functions, will consist of exciting and inhibitory nerves. However, I am not discussing this question here. I only maintain that the nerves for excitation and inhibition have directly nothing to do with the processes of catabolism and anabolism. At the same time it is quite obvious that the inhibition of the expenditure of potential energy will have, indirectly, trophic influences. We can thus well understand why, after a prolonged standstill of the heart due to a stimulation of the vagus, the heart contracts more energetically for some time; the muscle has at its disposal a surplus of unexpended potential energy. On the other hand, unrestricted excitation with increased expenditure of potential energy, perhaps out of proportion to its normal production, ought to lead in the end to atrophic changes of the organs. We can thus explain the fatty degeneration of the heart observed to take place after section of the vagi as being due simply to overaction of the heart without recurring to the assumption that the vagus is the trophic nerve of the heart. Besides the larger expenditure of potential energy, the overaction leads to an overproduction and abnormal accumulation within the heart muscle of catabolic products which will assist in the disintegration of the muscle tissue.

The Relations of the Antagonistic Forces† to Stimulation.—Let us now examine the manner in which both antagonistic forces (or energies) respond to stimulation. Between the extreme conditions of activity and rest there are innumerable intermediary states, all of which we claim are resultants of simultaneous stimulations of excitation and inhibition. By what manner of stimulation is this great variety of states accomplished? Why are stimulations responded to at one time by an excitation, at another by an inhibition? If all stimuli would affect at all times and under all conditions both forces in exactly the same manner and to the same extent, it is obvious that stimulation could affect no perceptible change. It is, therefore, safe to assume that there is some difference in the way each responds to stimuli. The simplest solution of the problem would appear to be to assume that each force is affected only by a certain kind of stimuli. However, to my knowledge, there is as yet in the entire biology not a single fact which can with certainty be interpreted as indicating an absolute specific stimulation of either of the forces. On the contrary, wherever there is an occasion for either of the forces to be reached separately by a stimulus it is found that all known stimuli are effective for either force.

A study of the relations of inhibitory nerves to their antagonists in the small group of mechanisms in which both kinds of nerves are to be met with separately, throws light upon our question. I am now going to discuss these relations:

The vagus is the inhibitory and the accelerator is the motor nerve of the heart. Electric stimulation of one causes inhibition and of the other acceleration of the heart beat. When, however, vagus and accelerator are stimulated simultaneously with the same electric current we then observe during stimulation nearly only the inhibitory influence; this effect is only a trifle less than that which would have resulted if the vagus had been stimulated alone. We see here a stimulation of both antagonists producing an effect in favor of inhibition. The predominance of inhibition is so great that we could have been led to the belief of the absolute neglect or suppression of the excitation had it not been for the following very important circumstance. Vagus and accelerator differ in their after-effects. When the vagus alone is stimulated the inhibitory effect disappears very soon after discontinuation of the stimulation. If, however, the accelerator alone is stimulated, its effect lasts for quite a considerable time after the stimulation has been discontinued. Now, when both nerves are stimulated together, we see after the cessation of the stimulation the after-effect of the stimulation of the accelerator coming out in the same manner as if it had been stimulated alone. These facts are very important for us. Although the effect of inhibition is manifestly favored during stimulation, excitation is neither suppressed nor neglected, but is stimulated just as strongly as if there had been no inhibition; and its effect comes to the surface as soon as inhibition is removed. The difference in the length of the after-effects is here the means of the discovery of the presence and activity of one force during the predominence of its antagonist. By this method it was discovered that the vagus of some animals contains also some accelerator nerve fibers. There are other small differences between the antagonistic forces which can be and have been utilized for the same purpose. For instance, the difference in their resistance to fatigue. The inhibitory nerve fibers become exhausted more easily and sooner than the accelerators. When, therefore, vagus and accelerator are stimulated together with a strong current for a long time we see the inhibition which sets in first gradually changing to acceleration, owing to the exhausted condition of the vagus, while the accelerator still remains intact for some time.

---

*The comparison with the stop-cock should only serve to bring out my chief contention that inhibition and excitation are not to be confounded with the generation of materials or their expenditure. I do not wish, however, to be understood to claim that the mechanism of excitation and inhibition is simply that of a stop-cock. While I shall not attempt to offer a theory as to the exact construction of this mechanism, I am sure it is not as simple as that of a stop-cock.

†Energy would here be probably a more correct designation than the often abused term of force. It seems to me, however, that energy, with the meaning attached to it here, is too technical a term to employ in a paper not written for physicists. But in employing the term force here in connection with vital processes, in order not to be misunderstood I wish to state explicitly that my views laid down here have nothing to do with the old or new forms of belief in vital forces.

Similar but reverse conditions exist between the antagonistic vasomotor nerves of the submaxillary gland. The sympathetic carries the vasoconstrictors and the chorda carries the vasodilators. Here excitation is the favored force during stimulation and inhibition has the long after-effect. When chorda and sympathetic are stimulated together constriction prevails during stimulation, but strong vasodilatation sets in after discontinuation of the stimulus as a result of the masked but undiminished simultaneous stimulation of the chorda. Furthermore, here the inhibitors—vasodilators—fatigue sooner than their antagonists. Another differential point between the cardiac as well as the vascular antagonists is the length of their latent period. But, again, in the vascular mechanism it is the inhibitory nerves, while in the cardiac mechanism it is the exciting nerves which have the longer latent period.

We learn from the laws governing these two pairs of antagonists that although the representatives of both forces are simultaneously stimulated by the same agent it is often practically the effect of only one force which is manifest during the stimulation, and that it is neither always inhibition nor always excitation which is more favored by the stimulus, and that no matter which of the forces shows its predominating effect during stimulation the activity of the antagonistic force is only masked, but is in no way destroyed or even impaired. Some differences in the properties and the behavior of both antagonists toward certain conditions serve to unmask the full activity of the less favored antagonist. We have learned some of these differences: the longer latent period, the longer after-effect, and the greater resistance to fatigue, none of which, however, are special properties of inhibition or excitation. We shall not omit to bring out the fact that during the simultaneous stimulation of the two antagonists, the visible effect, though apparently dominated by only one force, is nevertheless in reality, a resultant of both forces, the influence of the opposing force, though comparatively small, can always be demonstrated.

We have also to bear in mind that our knowledge of the overshadowing influence of one force was obtained in artificial stimulations of both nerves. The conditions are apparently less extreme where normal impulses are concerned, as can be seen by the facts that an artificial stimulation of the chorda overwhelms the tonus of the sympathetic or an artificial stimulation of the accelerator overwhelms the normal tonus of the vagus.

The two pairs of antagonistic nerves, the relation of which we have just discussed, nearly exhaust the number of mechanisms of the body in which both antagonists can be found to exist in two separate nerve trunks. However, the extensive studies of the presence of the vasomotor antagonists in many of the nerve trunks of the body brought to light a number of other differences in the behavior of the antagonists which are of assistance in their recognition and separation when running together in the same nerve trunk. Here are some of these differences. When a nerve trunk is cut the vasodilators in it degenerate later and regenerate earlier than the vasoconstrictors. Vasodilators resist the influence of cold longer than the constrictors. Vasoconstrictors require for their stimulation stronger and more frequent electric shocks than the dilators; e.g., lighter or less frequent electric shocks might bring out the activity of the vasodilators alone. The maximum effect of stimulation is reached later and lasts longer than the stimulation of the dilators. These differences, too, like those mentioned above, are not simply stable relations between inhibition and excitation in general; they have their validity for the vasomotors alone, and have to be especially tested when any other function is studied.

The variability of such characteristics is strikingly demonstrated in the behavior of both antagonistic muscles of the claw of a crayfish toward the strength of the stimulus. Biedermann found that a moderate stimulus inhibits the adductor and a strong one contracts it, while it is the reverse with the abductor: a moderate stimulus contracts it and a strong one inhibits it. The lighter stimulus favors inhibition in one and excitation in another muscle. These observations are very instructive. The moderate stimulus which inhibits the adductor excites at the same time the abductor. The stronger stimulus inhibits the abductor and excites the adductor. By this arrangement it is possible for the different stimuli to cause the contraction of the muscle without the interference of the antagonistic muscle. Here we see that the greater susceptibility to a stimulus is not a specific property of either of the antagonistic forces nor of the antagonistic muscles. It is simply a part of a complex mechanism to facilitate the proper working of a complex motion.

The same holds good for the other differences between the antagonistic nerves which we have recorded above. The predominence of the effect of one force during stimulation, the long after-effect, the long latent period, the resistance to fatigue, etc., are not peculiarities of inhibition or excitation, neither do they belong to one class of tissues or organs.

They are devices employed in all the mechanisms of the body for the purpose of properly accomplishing certain functions and their employment differs according to the necessities of each mechanism. Excitation and inhibition, probably, are in all normal tissues in a given animal the same, and both, probably, would respond in the same way to a stimulus of the same character and the same strength. However, on account of the necessity of its specific activities of various functions, in each case specific devices are attached, by virtue of which one force predominates during stimulation, the other after its discontinuation—one responds to a lighter stimulus or responds later or fatigues easier, etc. We may, therefore, say that the great variety of conditions and states met with in the animal body is due chiefly to the variety of the constructions of these devices, of which, probably, we do not yet know all.

Some years ago I tried to explain the self-regulation of respiration and heart beat on the principle of the predominence of one force during stimulation and of the other force after the discontinuation of stimulation. I shall not discuss this subject here.

Neither shall I attempt to discuss the applicability of our new point of view to many other well-known physiological facts. I wish, however, to discuss here the behavior of the skeletal muscles in the light of the relations set forth above. A skeletal muscle responds to a stimulus applied to the motor nerve or to the muscle itself with a rapid contraction and a rapid relaxation. We stated above that the muscle possesses inhibitory nerves and also that the muscle tissue itself can respond with inhibition. Why do we never notice the activity of the inhibitory forces? My answer is that the relations of the antagonistic forces within the motor nerve and the muscle are exactly the same as those which we have seen to exist in the vascular mechanism of the submaxillary gland, *i. e.* excitation predominates during the simultaneous stimulation, but inhibition possesses here a longer after-effect, which appears unrestrained after the cessation of the stimulation. In the muscle, too, the inhibitory force possesses a longer after-effect than the motor power; but during stimulation the motor force is the favored one. Therefore each stimulus causes a contraction, which, perhaps, would be even stronger if it were not for the moderating effect of the masked but present inhibition. As soon, however, as the stimulation is discontinued, the after-effect of inhibition, now unrestrained, causes the rapid relaxation of the muscle.

This represents the normal condition. We might, however, assume that there could be such an influence which would cause the stimulation to favor the inhibitory force and give the long after-effect to the excitation, then the conditions might be reversed and become similar to those of the cardiac mechanism, *i. e.* inhibition predominating during stimulation and contraction after the cessation of the stimulation, which means that the muscle would remain relaxed or even become more relaxed during stimulation, but would respond with a contraction at the discontinuation of the stimulation. Now to my mind this is, indeed, the condition which we observe to take place in the following experiments: When a muscle is stimulated with a strong galvanic current we see at the point of the anode no contraction, but we see a tetanus following after the opening of the current. This is the so-called Ritter's tetanus. I would explain it as follows: The anode stimulates excitation and inhibition, but it favors inhibition; therefore quiet reigns during stimulation, but at the interruption of the stimulus the unrestrained after-effect of the excitation causes the tetanus, which is here similar to the increase of the number of the heart beats after the discontinuation of the simultaneous stimulation of vagus and accelerator.

The second experiment I wish to quote was reported by Aklund. When the leg of a curarized frog was irrigated by a solution containing 0.5 per cent. of sodium chloride and 1 per cent. of sodium phosphate no movement of the leg took place during irrigation, but after the irrigation was discontinued a tetanus set in. I explain it as above. Sodium phosphate stimulates both, but favors inhibition; therefore, the rest during irrigation and tetanus after its discontinuation.

The Importance of Inhibition.—The importance of inhibition to the proper regulation of animal life is quite evident and needs no extended discussion. Many of the stimuli which keep up the activity of the body come from sources over which the animal body has no direct control, and the presence of inhibition is apparently indispensable for the regulation of the effects of these stimuli. If, for instance, the vascular system were controlled by the constrictors alone, they might often be affected by intense and lasting stimuli, which would cause complete and lasting constriction of the small arteries, thus producing anæmia and necrosis of the tissues. Furthermore, without muscular inhibition, the body might be permanently in an unendurably rigid state, or as Loeb puts it, if it were not for the inhibiting effect of the Ca- and K-ions, the Na-ions would turn all the muscles into pulsating hearts. However, besides its presence in each living tissue, inhibition is a wide-spread factor in the complicated activity of composite functions. Of this rôle of inhibition we have hitherto only spoken incidentally; it, however, deserves a special discussion. Many motor functions of the body depend for the proper discharge of their activity upon alternating contractions of antagonistic muscular parts—for instance, flexors and extensors, adductors and abductors, etc. Twenty years ago I suggested that the contractions of one group of muscles are probably accompanied by a simultaneous inhibition of the antagonistic group. I also pointed out that such a mechanism is actually present in the respiratory function. Each inspiration is accomplished by an inhibition of the expiratory and a contraction of the inspiratory muscles, while each expiration consists of an inhibition of the inspiratory and a contraction of some of the expiratory muscles. Furthermore, the nerve fibers for the inhibition of the inspiratory muscles and the contraction of the expiratory muscles are often carried in the same nerve trunk—for instance, the superior laryngeal, etc. Biederman further found the above-mentioned remarkable fact that in the stimulation of the nerves of the claw of the crayfish the strength of the stimuli which causes the contraction of the adductor causes also inhibition of its antagonist, and the strength which causes the inhibition of the adductor, causes the contraction of its antagonist. In other words, the same strength of a stimulus causes contraction of one muscle and inhibition of its antagonist. The recent experiments of Sherrington have brought many proofs for the correctness of the above-mentioned suggestion. He established, for instance, that the contractions of the internal rectus muscle of the eye are accompanied by an inhibition of the tonus of the external rectus muscle and *vice versa;* and that the contractions of the orbicularis palpebrarum are accompanied by an inhibition of the tonus of the antagonistic levator and *vice versa.* Furthermore, Sherrington and Hering have found that in the cortex the stimulation of the center for the contraction of one group of muscles—for instance, the flexors—causes simultaneously an inhibition of the antagonists, the extensors, etc. From the experiments of Biederman and of Sherrington can be learned, further, that the stimulation of the foot of a reflex animal while, for instance, in a state of flexion, will cause inhibition of the flexors and contraction of the extensors of the same leg, with, perhaps, an opposite effect in the other leg. Compression or contraction of one muscle—the flexor for instance—will cause inhibition of its antagonist. The arrangements for the proper execution of this "crossed innervation," as we may call it, are apparently located in the central organ in the cortex, as well as in subcortical centers or in the medulla. The inhibition of one part, for the purpose of assisting the proper activity of another part, is an essential mechanism in many functions of the body. We have seen it in the functions of locomotion, respiration, and the movements of the eyes and lids. We can recognize it also in the vascular system, inasmuch as the constriction of one vascular region is usually accompanied by a dilatation of the blood vessels of another region. The diastole of the ventricles during systole of the auricles is, perhaps, another instance of this mechanism. In the œsophagus we see inhibition running ahead of the peristaltic contraction; in the intestines each contraction is accompanied by an inhibition in the section below. I shall not burden you with many more instances.

"Crossed innervation" is certainly an important and widespread mechanism in a great many functions of the animal organism.

In considering the importance of inhibition we have also to distinguish between its activity in the tissues and its activity in the organs. Regarding both we may, however, formulate the following statement: the activity of an organ is a resultant of the excitation in one part and inhibition in the antagonistic part; the activity of a tissue is the resultant of excitation and inhibition in the same part.

THE RÔLE OF INHIBITION IN PATHOLOGICAL STATES OF LIFE.

Let us now turn to the rôle of inhibition in pathology. We have just seen that the entire life of the animal organism is a delicately adjusted equilibrium between excitation and inhibition. Can there be any doubt that this equilibrium is liable to be disturbed in many ways? There might be, in the first place, a congenital or acquired stationary or temporary deviation from the normal resultant in favor of one force or the other through the entire animal organism. All functions might show a greater or less tendency toward inhibition or toward excitation. The deviation might be due either to an increase or to a decrease of the value of one of the forces, or even to a simultaneous increase of one and decrease of the other force, or the value of each force separately might be unaffected but their mutual relations might be shifted in favor of one or the other force. Further there might be a deviation only within a part of the functions of the body, or one part might deviate in one direction while the other is deviated in the opposite direction. The same applies to deviations within a single organ or function. The equilibrium might be disturbed within one part of the organ or the disturbance might have reference to the "crossed innervation," the equilibrium between its antagonistic parts. Finally the disturbance might be confined to one of the minor differences between the two forces—for instance, the latent period—the after-effect, the resistance to fatigue, the minimum stimulus, etc. The possibilities are very numerous, and I shall not attempt to enumerate them all and still less to illustrate them. In discussing the relations of inhibition to abnormal states I shall confine myself to a brief discussion of a few pathological pictures which can be, I believe, profitably commented on from the new point of view which I have presented.

Cardiospasm.—I shall begin with a brief comment upon the condition now known under the term of cardiospasm, a subject in which I have some personal interest. Some fourteen years ago I described a case of dysphagia which I diagnosticated as cardiospasm. The diagnosis was then, as far as I know, quite new. We have now quite a considerable number of cases of that kind on record. The pathology of this disease, as I understand it, is as follows: The cardia is normally in a state of moderate tonic contraction. The tonus we now know is a resultant of simultaneous activity of motor and inhibitory nerves. The force of the normal tonus is adjusted by two opposing considerations. It has to be able to resist the force resulting from the contractions of the stomach in order to prevent the escape of the chyme from the stomach into the œsophagus, and it has to give way to the opposing force coming from the contraction of the lower end of the œsophagus in order to permit the entrance of the food into the stomach. A shifting of the resultant within the tonus in favor of the motor force will cause an obstruction which could not be overcome by the contraction of the œsophagus. That is what happens in cases of cardiospasm. The deviation from the normal need not be great: any deviation would be sufficient to neutralize the effect of the œsophageal contraction. In some cases, however, the shifting of the resultant in favor of the motor component is apparently considerable, as can be seen from the fact that such patients are unable to vomit, which means that even the strong inhibition of the tonus of the cardia which usually precedes each vomiting is unable to overcome the spasm. There are no primary anatomical changes in this form of dysphagia; in long standing cases a consecutive dilatation of the œsophagus is found at autopsy, which, however, does not involve the cardia. Here we have an instance in which a comparatively insignificant functional disturbance, due to a moderate deviation of the resultant in an insignificant mechanism, leads to very serious consequences to life.

Disturbances in the Biliary Passages.—In taking up now some of the disturbances in the flow of bile I shall have to discuss first the innervation of this mechanism. The secretion of bile within the liver goes on continually, but its discharge into the duodenum occurs only during the act of digestion, beginning about one hour after a meal. When the digestion is finished the bile flows from the hepatic through the cystic duct into the gall-bladder. What is it that turns the bile current away from the intestines towards the gall-bladder during rest? This question has hardly as yet been seriously discussed, not to say satisfactorily answered. Recent investigations by Doyon, however, have thrown a flood of light on the mechanism controlling the biliary paths. Stimulation of the peripheral end of the splanchnic nerve causes contraction of the gall-bladder and the relaxation of the circular muscle fibers within Vater's papilla, or Oddi's muscle, that means that the splanchnic nerve contains motor fibers for the gall-bladder and inhibitory fibers for the sphincter of the bile duct. The vagus, on the other hand, contains motor fibers for the sphincter and inhibitory fibers for the gall-bladder. At rest, the pair of fibers in the vagus is at work—that is, the sphincter of the bile duct is closed and the gall-bladder is inhibited, relaxed; the stream of bile therefore flows into the bladder. During digestion, however, this pair is set at rest and the pair of nerve fibers within the splanchnic nerve becomes active; that is the gall-bladder contracts and the sphincter of the bile duct is inhibited, relaxed; the current of the bile therefore is turned toward the intestines. We see here the same "crossed innervation" between the antagonistic parts of the same function as we have seen it exist between such antagonists as flexion and extension, expiration and inspiration, etc. We have here, still further, the complication that both nerves contain also crossed innervation in the centripetal direction. But this part of the mechanism we shall not discuss here, in order not to obscure our subject by too great complexity. The explanation of the mechanism is then this: one hour after a meal something takes place which causes a contraction of the gall-bladder, and inhibition of the sphincter of the bile duct, and the bile is then driven into the intestines. We shall add here that, according to Bruno, this something is the entrance of the digested food from the stomach into the duodenum which causes reflexly the activity of this part of the mechanism. It seems that only fats, peptons and albumoses are effective; but not acids, alkalis, etc. The proper activity of the mechanism depends upon the exact adjustment of the resultant of inhibition and excitation in each part as well as between the antagonistic parts.

In pathology of the biliary passages we speak almost exclusively of only one cause for the disturbance in the proper discharge of bile into the intestines, and that is the mechanical obstruction of the bile passages. This can be accomplished, it is stated, in two ways—by catarrhal swelling of the mucous membranes or by the presence of a foreign body within the duct, generally a biliary calculus. May we not expect also the occurrence of disturbances in the complicated and delicately adjusted nervous mechanism? Could it not happen here, as it often happens elsewhere in the functions of the body, that some part of the reflex mechanism becomes impaired? I believe that such disturbances do occur, indeed, but the occurrences are largely misinterpreted, owing partly to the lack of knowledge of the nervous mechanism and partly to our preferences for mechanical interpretations of phenomena. I shall now attempt to discuss some of these disturbances.

There are four different possibilities. It might happen: (1) That the sphincter remains contracted and the gall-bladder relaxed, even during digestion; (2) That the sphincter remains relaxed and the gall-bladder contracted even during rest; (3) That there might be a deviation of the resultant between excitation and inhibition in favor of excitation, and (4) That the deviation might be in favor of inhibition. Let us now consider, first, the first-mentioned disturbance, namely, that the sphincter remains contracted and the gall-bladder relaxed during digestion. This disturbance can be brought about by three different causes: (*a*) The activity of the center might for some reason be diminished and no impulses of sufficient strength would be sent through the nerve fibers of the splanchnic to the periphery during digestion; (*b*) The peripheral area of the duodenum, etc., from where normally the reflex takes place, might be less irritable and would not respond to the normal stimuli; (*c*) The stimuli might be abnormally weak and would be insufficient to bring out the reflex. In any case the gall-bladder and sphincter of the bile duct will remain during digestion in the same condition as they are during rest—that is, the sphincter will remain closed and the gall-bladder relaxed. The result will be that the continually secreted bile will accumulate more and more in the gall-bladder, will distend it far above normal until the natural resistance of its tissue will stem the further flow and cause a stasis of bile within the bile capillaries of the liver tissue. In short, a disturbance of the reflex mechanism which is normally instrumental in turning the flow of the bile into the intestines will be followed by all the consequences which we now know to follow a mechanical obstruction of the biliary passages, especially in catarrhal icterus. Do such nervous obstructions really occur? Many might be willing to admit that, for instance, the "emotional icterus," which is chiefly described by French writers, is of nervous origin, and might be caused by such a disturbance of the reflex mechanism as I have described here. However, I venture to go farther and claim that many of the cases which are diagnosticated as "catarrhal icterus" are in reality caused by a nervous obstruction. The proof for the assumption that an icterus and its allied symptoms are brought about by an obstructing catarrh of the biliary passages is usually seen in the fact that a gastric catarrh preceded for a few days the onset of the icterus. Let us suppose that this is, indeed, a reliable proof. But how about the cases in which a preceding gastric catarrh is missing? I have seen not a few cases in which an enlarged gall-bladder and enlarged liver, dull pains in the right hypochondrium and even in the epigastrium, finally icterus and acholic stools, etc., were present for some time before any reliable sign of a gastric catarrh made its appearance. Judging from my own experience, it would seem to me that the cases of icterus with a preceding distinct gastric catarrh do not form the majority of the so-called cases of catarrhal icterus.

However, I believe that even the presence of a preceding gastric catarrh is by no means a proof that the icterus was caused by a catarrh present in the bile duct. We have seen above that the reflex which causes the flow of the bile into the intestines during digestion is caused by entrance of normally digested food into the duodenum. Now, in some cases of gastric catarrh the chyme might reach the duodenum in an incomplete state of digestion, or the chyme might be enveloped by a layer of mucus, and thus not be in a position to stimulate the reflex mechanism efficiently. The failure of the bile to reach the duodenum might therefore also in these cases be due rather to a failure in the activity of the reflex mechanism than to a catarrh of the biliary passages.

These points deserve a serious consideration, the more so as the number of cases of pure catarrhal icterus which come to autopsy is comparatively small and the diagnosis of the presence of an unmistakable catarrh in the bile duct does not seem to be an easy matter and above doubt, even at the post-mortem, and the stagnation of bile within the duct from any cause whatsoever might produce an irritation and a reaction of the mucous membrane of the bile duct. I do not wish to be understood to mean by this that I deny the occurrence of an icterus of a purely catarrhal origin. I only suggest that disturbances in the nervous mechanism might produce conditions which might simulate exactly the so-called catarrhal icterus, and that therefore many of the latter cases, be they with or without gastric catarrh, might in reality be caused by the above-described disturbance of the nervous mechanism.

The theory I offer seems to me to be quite simple. During rest there is a mechanism in activity which causes a normal stagnation of the bile. During digestion a reflex is delicately stimulated, which sets another mechanism into activity for the discharge of the bile into the intestine. I suggest that sometimes the stimulus might be inadequate or the reflex less responsive. The result is that the mechanism acting during rest continues to work also during digestion, hence the pathological stagnation.

I shall now discuss briefly the above-mentioned third possibility of the functional disturbances of the nervous mechanism. It is the deviation of the resultant between excitation and inhibition in favor of the former. Through the influence of some pathological cause it may happen that the sphincter of the bile duct and the gall-bladder contract simultaneously. I believe that the foremost symptom which this disturbance could cause is colicky pain in the right hypochondrium. To explain my position I shall have to discuss briefly the mechanism of colic in general. The term colic is used chiefly, as we all know to designate the characteristic pains in the bowels. Nothnagel and some other writers believe that a strong single constriction of some part of the gut is the cause of this pain. It seems to me that a simple strong contraction of an empty part of the gut could never cause such severe pain as seen in colic. Even in normal peristalsis the intestines sometimes contract *ad maximum* without causing pain. I believe that colic occurs—chiefly, at any rate—when two places of the gut not far apart are strongly contracted simultaneously, especially when the lower contraction is more stationary, while the upper one progresses downward. The part of the gut which lies between the constrictions becomes distended by its gaseous contents to an extreme degree: hence the terrific pain. In the normal procedure of peristalsis, as has been shown by Bayliss and Starling, simultaneously with each contraction a relaxation of the adjacent lower part of the gut takes place so that the contents can pass downward easily. Relaxation and contraction are parts of one function and belong together, as, for instance, the inhibition of an extensor muscle belongs to the efficient contraction of the flexor. When the equilibrium is disturbed in such a manner as to favor excitation, two neighboring parts might contract simultaneously, and the result would be colic. The same process takes place when the stomach is strongly bent on the expulsion of its contents into the duodenum and the pylorus remains firmly contracted; severe cardialgic pains are the result. And I believe that exactly similar conditions occur in the biliary passages: the gall-bladder contracts strongly while the constrictor of the bile duct is firmly contracted; the result is biliary colic. This is probably the mechanism in cases of nervous liver colic and neuralgia of the liver which has already been mentioned by old writers on diseases of the liver—Frerichs, for instance. The same can be said of the cases described as menstrual colic of the liver. By some reflex influence during menstruation the normal resultant in the mechanism of the biliary passages is deviated in favor of excitation, so that both antagonists are contracted and neither is inhibited. However, even some of the plain cases of gallstone colic in which no calculi could be detected might actually belong to this type of nervous colic. I remember a case of a woman with a history of gallstone colic who, after losing her only daughter, again started in with severe typical attacks of gallstone colic. The gall-bladder was palpable, the liver enlarged and painful, icterus was present and the stools were dry and acholic. Nevertheless her condition improved, not under a "Carlsbad-cure," but under valerian, bromides, etc.

Of the two other possible disturbances which I have mentioned above one will probably prove to be of practical value and interest, namely, that the mechanism controlling the activity of the biliary passages during digestion continues to act also during rest, and that the flow of bile into the duodenum is a continuous one. I shall, however, not enter for the present into a discussion of these possibilities.

We have stated above that the deviation from the normal might be confined to a tissue and that the disease might either affect inhibition or excitation or it might be confined to minor points in the relations between the two forces. In the following I shall attempt briefly to apply these principles to a few obscure diseases in which chiefly the activity of the skeletal muscles are concerned.

Family Periodic Paralysis.—I shall discuss first that syndrome which is now termed family periodic paralysis. Thirty to forty cases are now on record in which persons otherwise healthy are periodically attacked with a temporary paralysis of nearly all the voluntary muscles of the body. The paralysis lasts from a few hours to a few days, onset and disappearance being comparatively abrupt. The most striking feature of this paralysis when complete is the total absence of indirect or direct irritability of the paralyzed muscles to mechanical or electrical stimulation, in the latter not even then when the needles are introduced directly in the muscle. There are many theories and some experiments as to the cause of this condition, but there has been hardly any discussion as to the nature of it. The comparison with the effects of curare is incorrect, as curare does not affect the direct irritability of the muscle. Dr. James J. Putnam, after a private conversation with myself, advanced the theory that the condition is a state of inhibition. I believe that this theory is correct. The muscles behave like the heart muscle when under the influence of a strong vagus stimulation. We have stated above that any condition of the normal muscle is a resultant of inhibition and excitation, and that normally the skeletal muscle responds to stimulation in the same manner as seen in the vascular mechanism of the submaxillary gland, namely, that excitation prevails during stimulation. We meet now in this disease a condition in which excitation and inhibition assume relations such as exist between the antagonistic nerves of the heart, that is, inhibition prevails during stimulation. The disease is a temporary extreme deviation of the normal resultant in favor of inhibition, just as a continued rigidity or spasm is a deviation in favor of excitation. This explanation of the nature of the disease does by no means make the search for its cause superfluous. On the contrary, the discovery of the cause of this disease might throw some light upon the fundamental question of the conditions which influence the phenomenon of inhibition. However, it seems to me that we need not search for toxins and the like as the cause of this pathological condition. Loeb's experiments on artificial parthenogenesis have taught us what profound effects can be produced by comparatively slight changes in the composition of the inorganic salts in a fluid. In our disease I am thinking of a temporary overproduction of the phosphates in the affected muscles. According to Biedermann, potassium monophosphate abolishes the excitability of a muscle which can be re-established by washing it out with normal salt solution. There are in the tables given by J. K. Mitchell (Transactions of the Association of American Physicians, 1901) of the analysis of the urine of such patients some figures which might prove to be quite important. The urine voided soon after the paralysis passed off contained nearly three times as much phosphates as was found in the urine of this patient during the period of health. The phosphates found in the urine during the attack was about normal, and therefore the increase of the phosphates in the urine immediately after cessation of the disease can be accounted for only by an overproduction of the phosphates in the muscles. Future researches will have to clear up this important point.

Myasthenia Gravis.—A similar explanation might be offered for the Erb-Goldflam disease or myasthenia gravis pseudoparalytica. The disease consists in a paretic condition of the extrinsic muscles of the eye, of the muscles of the face, tongue, neck and often also of some muscles of the trunk and extremities. Some of the involuntary muscles are also involved. The disease fluctuates, but is usually fatal.

No anatomical lesion has been discovered in the cases. The excitability is only moderately diminished and that not in all cases. The main characteristic of the disease is the rapid exhaustion of the affected muscles in normal stimulation, as well as in stimulation by the faradic current. My interpretation of this functional disturbance is as follows: We have seen above that excitation and inhibition do not develop the maximum of their effect at the same time. In the vascular system, for instance, inhibition reaches its maximum effect much later. We might assume then that in the motor mechanism of the affected muscles in myasthenia gravis there is a moderate deviation from the normal in favor of inhibition, but that the latter after each new stimulation reaches its maximum effect quite slowly, but is then strong enough to overwhelm the excitation. On account of a greater participation of the component of inhibition in the general resultant, the muscular tone, even at rest, is distinctly diminished. After an extra stimulation, normal or artificial, excitation at first gets along fairly well. As soon, however, as the simultaneously stimulated inhibitory force reaches its maximum effect, excitation becomes subdued and the muscle appears to be fatigued.

Myotonia.—I shall now touch upon that functional disease termed myotonia or Thomsen's disease. The chief characteristics of this disease are as follows: Single voluntary contractions or single contractions caused by direct mechanical or electrical stimulation of the muscles continue for some time, twenty to thirty seconds or longer. In a continued series of contractions this impediment disappears very soon. The beginning of each single contraction seems to be slow and awkward. There seems to be some increase of the excitability of the muscles. No anatomical lesions were found in this disease. The changes reported to be found in the structure of the excised muscle fibers are, as Geo. W. Jacoby has shown, histological artefacts. The main characteristic of this malady I shall illustrate by the following striking feature: If such a patient be told to shut his eyes he will be unable to open them for some time. Now Sherrington has experimentally demonstrated that during the motor innervation of the levator, inhibitory impulses are sent to the orbicularis palpebrarum, either to relax it or to prevent its contraction. Therefore, it seems to me that if this patient be unable to open his eyes, though the levator be intact, this can only mean that the inhibitory impulses are not efficient enough to overcome the undisturbed long after-effect of the contraction of the orbicularis. The inhibition, however, is apparently not abolished, as there is no such impediment when opening and closing is continued for some time. My interpretation of this pathological phenomenon is as follows: There is in this disease only one deviation from the normal, and that is that the latent period for inhibition is considerably prolonged. In a normal muscle the inhibitory force might have the same latent period as the exciting force, and although it is in the main overwhelmed by the latter, the inhibitory force makes its presence felt in as much as it does not permit sub-minimum stimuli to cause a contraction. The latent period can be as long as twenty to thirty seconds, and even longer, as we know to be the case in the accelerator nerve and in the chorda. Such a long latent period will explain, in the first place, the prolongation of each contraction. We have stated above that the rapid relaxation of a muscle is due to the after-effect of inhibition. But in our case the excitation comes to an end long before the inhibition reaches its active state, hence the prolonged contraction. However, in a series of rapid alternating contractions the prolonged after-effect of inhibition from the first contraction is still present, while the second excitation passes off, therefore the rapid relaxation and the disappearance of the impediment when the work is continued. The length of the latent period has its drawback only in a single movement. Furthermore, the entire absence of inhibition at the beginning of a stimulation favors the effect of sub-minimum stimuli, therefore the increased excitability.

Finally, on account of the entire absence of inhibition during the beginning of the contraction, the antagonists are not inhibited, and therefore participate to a degree in the contraction of the chief muscle, which makes the latter somewhat slow and awkward.

Inhibition in Myxœdema and Graves' Disease.—I shall now discuss the relations of myxœdema and Graves' disease to the disturbances of the normal equilibrium between excitation and inhibition. It was stated above that one of the more striking disturbances of the equilibrium would be the deviation of the normal resultant in favor of inhibition or excitation, in all or most of the functions of the body. I am of the opinion that the diseases just mentioned present such deviations: myxœdema, with its outer relaxation, presents a deviation in favor of inhibition; and Graves' disease, with its restless activity, presents a deviation in favor of excitation. I do not mean to say that the deviations in one or the other are in each and every function of a considerable degree; it might be minute in one and extensive in another; some functions might not participate in the deviation at all, or might even have a deviation in the opposite direction. The general result, however, is a more or less pronounced deviation in one direction, either in favor of inhibition or excitation. I might add that greater predominence of one force is not necessarily brought about by an increase of the influences favoring that force; it might be due also to a decrease of the influences favoring the antagonistic force. We shall now attempt to discuss briefly some features of each disease in their relations to these forces:

In myxœdema the heart beats are less in number than normally, which is due to cardiac inhibition. The movements of the bowels are usually retarded—due probably to the inhibitory effect of the splanchnic nerves. The secretions of the sweat and lachrymal glands are inhibited. Reflex irritability, muscular excitability, power of perception, etc., are diminished. Muscular contractions are slow, perhaps, through inhibitory influences. The temperature of the body is lower than normal —perhaps through the action of the supposed inhibitory heat centers. All the muscles of the body seem to lack tonicity. The absence of any expression of the face is due to the entire lack of tonicity of the facial muscles; the presense of myxœdematous tissue could not abolish all expression, as there is no lack of it in very fat faces. The drooping of the upper lids is due to an inhibition of the normal tonus of the levators in addition to the presence of the myxœdematous tissue. The abundant formation of the myxœdematous tissue means pathological anabolism, which in itself means diminished activity or increased inhibition. While one or the other symptom of myxœdema might be interpreted in some other way, there can be no doubt, it seems to me, that there is in this disease a more or less distinct deviation in favor of inhibition in most of the functions of the body.

The reverse we observe in Graves' disease. The heart beats are considerably increased in number, due to the absence of the inhibitory tonus and, probably, also to a special excitation of the accelerator nerves. Diarrhœa is of frequent occurrence in this disease, some say owing to a greater secretion of the intestinal glands, but this might be assisted by a more active peristalsis of the gut, due to the diminished inhibitory influences. There is a greater activity of the sweat and lachrymal glands. Reflexes, muscular excitability, power of perception, mental activity are all increased. The intentional tremor I interpret in the following way: We know that lead with each voluntary contraction of a certain muscle, inhibitory impulses are sent to the antagonists, or to the undesirable synergists, to avoid their hindering by simultaneous contraction. When these inhibitory impulses are diminished and insufficient, irradiating impulses manage to reach these meddling muscles, hence the tremor. Intentional tremor means, therefore, also diminished inhibition. Stellwag's symptom, i. e. the greater width of the palpebral fissure and the diminished blinking, is due to an increase of the normal tonus of the levator. From Sherrington's studies upon the palpebral muscles and the extrinsic muscles of the eye, we are justified in assuming that the descent of the upper eyelid during the turning of the eye downward is due to an inhibition of the tonus of the levator, cortically connected with the contractions of the superior oblique and inferior rectus. Accordingly Von Graefe's symptom means only that the accompanying inhibition of the levator is diminished and therefore does not follow the downward movement of the eye to its normal extent. Even Moebius' symptom, that is the difficulty which is met with in accommodation for a near object, can be properly interpreted by the assumption that the inhibition of the tonus of both external recti is diminished, the internal recti have therefore a greater obstacle to overcome. Even for the exophthalmos itself, [illegible] opinion seems to me to merit consideration, namely, that it is produced by a simultaneous increase of the tonus of the superior and inferior obliques, which in themselves could pull the eye forward. Finally, the loss of flesh and increased catabolism observed in Graves' disease is certainly due to an increased excitation. I believe that a further study of this disease will bring out many more points tending to support the view that it presents in general a deviation in favor of excitation by diminished inhibitory influences at some points and increased excitability at other points of the body. There is, however, in Graves' disease the activity of one function which makes the impression rather of an increased inhibition; it is the behavior of the vascular system. I shall not speak of the exophthalmos, which is taken by many to be a result of vasodilatation as this is not proved and the symptom can be interpreted in another way. The same argument applies to the strong pulsations of some of the large arteries. But there are two symptoms which indicate clearly that the small arteries of the skin dilate with greater readiness than normal, these are the so-called tâche cérébrale and the ever present readiness to blush. And that means that in Graves' disease the vaso-inhibitors of the skin are more favored than in the normal body. There are two possible explanations of this phenomenon. One is that it is simply a fact that in the vascular system inhibition is favored, perhaps through the rapid beating of the heart and the increased activity of the thyroid which according to Von Cyon has a special relation to the depressor nerves. The second explanation is that the vasodilatation is confined to the skin, is only local and represents a collateral compensation of a constriction taking place in a much more extensive vascular area. We know that the largest portion of the blood is and certainly can be contained in the vessels of the abdominal viscera. When a constriction of the entire splanchnic region takes place the vascular system possesses an arrangement by means of which other vessels become dilated to accommodate the blood which was driven out and to relieve the vascular system from too high a pressure. It is possible that in Graves' disease the great vascular region controlled by the splanchnic nerves possesses, indeed, a tendency to constriction greater than normal, which would be in harmony with all other manifestations, and hence the greater tendency of smaller collateral areas toward dilatation. The latter explanation seems to me to be the probable one. The strong pulsation of the abdominal aorta which we meet with in Graves' disease will occur rather, as I believe, when there is a resistance offered to the outflow of a moderate quantity of blood which the rapidly beating heart is compelled to press into the aorta, than when the blood finds an easy outflow into a wide open bed. Besides, with a rapidly beating heart and the accumulation of the largest portion of the blood in the dilated splanchnic area the patient could hardly exist very long, and will certainly show neither too much blood nor too much pressure in the peripheral regions. I believe therefore that the tonus of the vasomotor center which controls chiefly the splanchnic region, is in Graves' disease in conformity with all other functions increased, and the vasodilatation which is observed in the skin is only of the nature of a collateral compensation.

As to the activity of the thyroid it is obvious that it has specific relations to both diseases, and ought therefore to have specific relations to inhibition and excitation. I shall however not enter into a discussion of the intricate problems in this paper.

Before I finish I shall touch upon one practical point. The purposeful studies of the relations between excitation and inhibition will lead to the recognition of conditions and substances which are capable of influencing these forces and their mutual relations. This knowledge will ultimately help us in our struggle to meet the deviations. In the course of this paper the inhibitory influence of phosphates upon the excitability of the muscle was referred to several times. Every one who had occasion to treat Graves' disease systematically with sodium phosphate has probably seen, like myself, its undoubtedly favorable effect upon the disease. The tremor improves first. I seriously believe that there is some sort of specific relation between sodium phosphate and inhibition, at least in the muscle tissue.

THE MERITS OF THE VARIOUS INCISIONS FOR APPENDICITIS

By JOHN A. WYETH, M.D., LL.D.,

NEW YORK

The merits of any incision for appendicitis must be determined by the condition which it is proposed to relieve. I employ but two, the "gridiron" or McBurney incision, and the "clean cut" through all the tissues from the skin into the peritoneal cavity.

The former should be selected when the conditions justify. As I practise it: A cut through the skin, at least three and oftentimes four inches in length, is made, and this, while parallel with the linea semilunaris, is made nearer the iliac spine, so that immediately beneath the cut through the skin the transverse fibers of the internal oblique and the transversalis muscles may be encountered. If the incision is made over the linea semilunaris, the separation of the muscular bundles will not give sufficient room, necessitating the division of this fascia, which, in my opinion, should be avoided when possible. When the external oblique aponeurosis is reached it is split in the direction of its fibers, and the edges held apart with retractors. With two dissecting forceps the muscular bundles of the internal oblique and transversalis are next separated down to the peritoneum, and these are strongly retracted with dull instruments. The peritoneum is now in sight and may be incised in any direction, preferably in the direction of the incision through the skin.

This peritoneal incision should be about one inch in length. An opening of this size permits the introduction of one or two fingers, enables the operator to feel and detach, by breaking up any adhesions, and to bring the appendix and a very small portion of the cæcum through the opening into the wound, where it can be easily held until the mesoappendix is tied off and the organ itself tied with a silk ligature about one-quarter of an inch from the cæcum, and then removed.

I prefer the silk ligature to any other method of treating the stump. I have used it in all of my operations except one, and have no reason to regret using it in any instance. The funnel-shaped stump left beyond the ligature is thoroughly swabbed with pure carbolic acid.

I use a running catgut suture for the peritoneal wound, and loose kangaroo tendon sutures for reapproximating the separated muscular bundles of the transversalis and internal oblique; interrupted kangaroo tendon for the external oblique fascia, and silkworm-gut sutures for the skin, which completes the technique.

This incision should be used in all "clean" cases, in those operated upon in the period of quiescence, and in others when the inflammatory and septic processes are limited either within the lumen of the appendix or immediately about its walls, and when there is no more than a limited local peritonitis. When there is a well-marked abscess, and the septic process has gone far enough to wall off from the peritoneal cavity the diseased organ, and the pus which is around it, I do not approve of attempting an enucleation of the diseased organ and the abscess wall formed by adhesions through such a narrow incision. It is safer to enlarge the opening and have a free field for operation rather than run the very considerable risk of spreading the sepsis and causing general peritonitis.

An incision shorter than three inches, except in cases of well-marked abscess, is not advisable. In this condition it is best to simply incise and puncture and drain the abscess, and an incision one inch, or one inch and a half long, may suffice in these simpler cases, for the operation simply resolves itself into opening an abscess in which, after the skin is incised, there remains nothing but the separation of the muscular fibers, after the McBurney method, and puncture of the peritoneum adherent to the abscess wall.

When such a condition of sepsis prevails as to require a careful operation to prevent widespread infection and peritonitis, I prefer the "clean" incision through everything from the skin, and including the peritoneum. When this is to be made it should be situated over and parallel with the linea semilunaris, in order to avoid cutting the transversalis and internal oblique muscles through their fibers, which retract and leave a weak line of union. It is safer to cut through the muscular aponeurosis which forms the linea semilunaris.

In this operation the peritoneum is sutured with catgut, the aponeurosis of the semilunaris with kangaroo tendon, and the skin incision with silkworm gut, or with a single row of sutures of this last-named material, which include the skin with the aponeurosis.

I wish to call attention to an error in technique which I have observed in reapproximating the separated muscular fibers of the internal oblique and transversalis in which the kangaroo tendon sutures were tied so tightly that the vitality of the muscle was destroyed.

When the "gridiron" incision is used it may not be necessary to keep a patient in bed as long as when the "through-and-through" incision is employed, but, since it takes five or six weeks for the new connective tissue bundles to become fibrillated and fairly well hardened, it has always seemed a wise conservatism to keep these patients in bed in the recumbent posture, in order to give the abdominal muscles as complete rest as is possible, and thus secure a union which is more apt to prevent ventral hernia than if they are allowed to sit up in bed or stand up or move about the room within three or four weeks after operation.

I require my patients to remain in bed six weeks after the "through-and-through" incision, and not even to sit up. Since I have carried this practice into effect I have not had a single case of ventral hernia following even, in some instances, extensive incisions. All the accidents of this nature that I have ever witnessed have resulted from permitting patients to get out of bed or sit up and move about at an earlier period.

REPORT OF A CASE OF CÆSARIAN SECTION FOLLOWED BY HYSTERECTOMY FOR IMPACTED CERVICAL FIBROID AND PROLAPSE OF GANGRENOUS UMBILICAL CORD IN A SEPTIC WOMAN; RECOVERY.*

By ABRAM BROTHERS, B.S., M.D.,
NEW YORK.

GYNECOLOGIST TO BETH-ISRAEL HOSPITAL; ADJUNCT TO THE CHAIR OF DISEASES OF WOMEN, NEW YORK POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL.

I believe that the case which I have to report presents a number of interesting and somewhat unusual features.

P. G., a married Italian woman, forty years old, had given birth to three children without difficulty and was now in labor with her fourth child. During three days a midwife had been in attendance, but, as there was no progress, Dr. E. G. Tuffs was sent for on April 12, 1902. He found a prolapsed umbilical cord and sent for Dr. H. B. Jones to assist him. Under chloroform anæsthesia, an attempt was made to reduce the cord and dilate the cervix. A hard mass seemed to block the pelvis, almost completely rendering all efforts at dilatation futile. I was then invited by Dr. Tuffs to visit the patient.

On placing the patient on the table the funis was found to be in a gangrenous condition and protruded a distance of six or eight inches from the vulva. On introducing the examining fingers the pelvis was found to be filled up with a rounded hard mass attached to the posteria cervical lip and practically filling the lumen of the bony pelvis. High up, anteriorly, the os cervicis was discovered as a slit wedged against the symphysis pubis. It was open a distance of several inches transversely, but, anteroposteriorly, barely permitted the passage of the two examining fingers. High up the fetal head could just be reached. The patient's temperature was 103° F and pulse 130. Delivery through the natural passages, even with the aid of craniotomy, was out of the question, and, although the child was known to be dead and the mother's chances of recovery after any form of intervention were very slim, I suggested immediate transferral to the hospital, with the object of performing a rapid Cæsarian section with removal of the dead fœtus and drainage of the uterus per vaginam. Under the desperate circumstances we intended to leave the tumor for subsequent consideration. The cord was replaced in the vagina and kept there with a gauze packing.

---

*Specimen and report presented at a meeting of the Bellevue Alumni Association, May 7, 1902.

Within an hour the patient was in the operating room at Beth Israel Hospital. With Dr. Goldstein as my chief assistant and in the presence of Drs. Todd, Jones, Gaertner, Freedman and the house staff, I made the usual longitudinal incision through the abdominal wall. A rubber tube was passed low down surrounding the uterus below the level of the tumor. As the uterus was drawn out of the abdominal cavity a large portion of the distended intestine escaped and caused considerable annoyance before it could be replaced and kept back with sterilised towels. The uterine wall was incised in the median line longitudinally and the membranes ruptured. A most offensive odor greeted our nostrils. The decomposing fœtus and gangrenous cord were extracted and the latter divided between clamps. The placenta, with its adherent membranes, was next removed. The patient's pulse not being any worse under the anæsthetic, it was decided, after thoroughly washing out the uterine interior with pitcherfuls of sterilized hot water, to remove the septic uterus at the same sitting. This was done in the usual manner, catgut being used to secure the vessels, and, after draining with gauze per vaginam and leaving a small strip at the lower angle of the abdominal incision, the wound was closed with worm-gut sutures embracing all the layers of the thin abdominal wall. This was done contrary to my usual practice of suturing the abdominal wall in three layers, because the operation had occupied somewhat more than an hour and I wished to spare the patient any additional shock.

Under the untiring efforts of Dr. Rabinowitch, the house surgeon, and of Dr. Goldstein, the house physician, the patient next day was in better condition than at the time of operation. Her temperature dropped to 101° F. During the next few days her bowels reacted after various cathartics and rectal enemata had been tried. She began to retain nourishment and temperature dropped to the normal. Everything pointed toward an uneventful recovery.

Excepting a certain irritability when given her food and medicines, we thought, from the little communication which we had with her in her native language, that she was in a normal mental condition. The nurse reported, however, that at times she seemed to be picking at the dressings.

On the ninth day pulse and temperature were normal. The dressings and sutures were removed and the wound was found to have healed by primary union. The patient, however, seemed to be unduly irritable and kept on muttering things which we could not understand. During the night she picked a good deal at the dressing and, in the absence of the nurse, jumped out of bed, evidently in a moment of mental aberration. This was only reported to Dr. Rabinowitch on the following morning. Examining the dressings he found them soiled and on their removal the wound was found to be gaping with eventration of some of the bowel. He very properly put the woman at once under anæsthesia, replaced the bowel and sewed the wound with the first suture material at hand, which happened to be chromicised gut. For several days the patient was in a septic state with elevated temperature and dry, brownish-coated tongue. She gradually emerged from this state and about the fourteenth day from the time of the first operation she was practically out of all danger. She is still in the hospital (at the end of three weeks) because the skin incision gave way again and will require, very probably, some secondary sutures or healing by granulation. (Two weeks later the patient was almost in condition to be discharged.)

To me the features of interest in the case were the following:

1. The fact that the woman had spontaneously given birth to three living children although the tumor must have been of some years' growth.

2. The recovery of the mother after cord and uterine contents had undergone decomposition with resulting maternal sepsis.

3. The mental derangement which showed itself about the ninth day and was evidently the direct result of the operation.

4. The escape of the intestines for several hours after the spontaneous reopening of the wound, without fatally influencing the progress of the case.

5. The desirability in sepsis preceding delivery (in cases requiring Cæsarian section) of immediately combining abdominal hysterectomy with Cæsarian section. The risk of additional shock is fully met by the advantage of removing from the woman's system the infected uterus. I have in similar cases, known women to die of subsequent septicæmia after the uterus had been emptied through the natural passages. Hence, sepsis preceding delivery offers to me a strong indication for the removal of the uterus either at the time of delivery or shortly afterwards if the septicæmia does not rapidly abate.

EXTERNAL SPEECH-PHYSIOLOGY, OR SO-CALLED LIP-READING.

By CORA D. GORTON,
NEW YORK.

As external speech-physiology may now be placed in the category of descriptive sciences, and as the art of lip-reading has been so systematized as to be acquired in a relatively short space of time, aurists and general practitioners are seeking enlightenment upon the subject, in order that they may understandingly advise with such of their patients who, being afflicted with defective hearing, may be benefited by a knowledge of the art of reading the lips.

This being so, it is my purpose to here set forth, briefly, some of the principles underlying the science, and to indicate how these principles may be applied.

While the present agitation of the subject may lead many to believe that this science is of somewhat recent origin, in reality it originated hundreds of years ago in foreign countries, but only within the last few years has it been reduced to an art by systematizing and arranging it upon scientific and phonetic principles.

The positions and actions of the organs of speech produced by the muscular activities of the mouth of a speaking person are most pronounced, and the eye is trained to read this rapidly-changing display of features automatically and correctly.

Every motion of the lips stands for something to the person who knows what to watch for and how to interpret it. One grows to note, unconsciously, every mark of facial expression. Through experience it becomes no tax upon the memory.

Faces differ in strength of expression, some speakers presenting an almost entirely blank one;

yet there *are* aids to be found, even with that most serious of impediments—the heavily-moustached mouth. Even under a short course of discipline the sight becomes unusually acute, and results, at times, are marvelous, the proficient reader often passing among strangers as an intelligent hearing person.

The vowel letters, a, e, i, o, u, according to the phonetic method, are presented to the pupil first, as they are *fixed* shapes with open apertures of the mouth, and have in speech longer duration than the consonants, thus showing stronger movements. These letters are used in the formation of all words, consequently, they form the life of speech.

The vowel sounds of words are unchangeable, while those of the consonants have transitional shapes, with closing and opening movements of the organs. The consonants are the initial and final elements used with vowels.

The number of syllables in a word uniformly corresponds to the vowels it contains. (The diphthongs, ei, eu, etc., are read as single sounds.)

In the word Ohio, for instance, containing three vowel letters, there are manifested three distinct syllables. In valetudinarian, where seven vowels are employed, a corresponding number of syllables may be noted.

Monosyllables are more difficult to read than many-syllabled words, as are single words than sentences. Context soon becomes an invaluable aid.

The characteristics of the vowel letters externally manifested are: (1) Changes in the form of the mouth; (2) The position of the lower jaw; (3) The movements of the cheek surface.

Each vowel letter has two or more changes; "A" has the greatest variety of sounds, and, according to my experience as an instructor of the art, the most important ones to be read from the lips are the long, short, Italian, and broad sounds.

Experiment before a mirror, if the reader chooses, with the following words, representing in order the four sounds mentioned, and you may form an idea of the distinctions as produced by the mouth in speaking them: fāmous, long a; fămished, short a; färmer, Italian a; fa̤lter, broad a. At all times the sounds are to be considered rather than the letters represented. To the skilled reader whole sentences appear as one long word, for he is taught to take it from the lips as a whole rather than to analyze it into its constituent parts. Not all words need necessarily be recognized in a sentence, nor are they to be read in detached form as before intimated.

During the elementary drill upon the vowel letters or sounds, the consonants are mastered also, as it is impossible to present the one in practice without the other. Conversation is made use of from the beginning, simple sentences slowly given at first, but leading gradually to the more difficult and complex, with rapidly pronounced words and profile views. In the formal drilling upon important sounds repetition is the surest aid to remembrance. Every sound that becomes familiar to the eye of the speech-reader becomes a key to every other word in which the same occurs. In this connection much attention is given to the systematic drill upon prefixes, suffixes, and all terminals which occur frequently in language.

One of the satisfactory methods for testing the reading, understanding, and general improvement of pupils is to address imaginary people in remote parts of the room, speaking naturally and at length, presenting, the profile and three-quarter views. Pupils thus learn to read the movements of the lips without the aid of the full-face expression.

Another beneficial and interesting diversion is to read to the pupil some short poem, or a paragraph from a newspaper, and have the same reproduced by questions from the teacher, or given in substance by the pupil. This process insures interest, for it is an important feature of the work to make, so far as is possible, all lessons interesting, and to demonstrate a gradual progress.

Exaggeration of the movements of the organs of speech in teaching lip-language to people who are merely deaf is to be deplored, as the pupil is thus hindered rather than helped to read the lips of strangers.

Pupils of ordinary ability will show marked improvement in the course of a few lessons, and frequently, after a few months of regular work, will become good readers. Great skill comes with practice, which must be constant and practical, such as one gets in daily intercourse with one's family and associates.

Experience proves that age, as a rule, makes but little difference in the acquirement of a knowledge of lip-reading. With a fair degree of intelligence, the art may be mastered at almost any age in life.

When one considers how deaf people are handicapped in all the walks of life, how hindered in business and social advancement, how the defect destroys ambition, and often leads to melancholia, the importance of a system which will reduce the evil influences of the affliction cannot be overestimated.

68 West Forty-ninth Street.

A NEW METHOD OF OPERATING FOR OBSTINATE CASES OF RECTOVAGINAL FISTULÆ.

By HIRAM N. VINEBERG, M.D.

ADJUNCT GYNECOLOGIST TO MT. SINAI HOSPITAL; ATTENDING GYNECOLOGIST TO ST. MARK'S HOSPITAL, ETC.

The method to which I wish to draw attention is one which I carried out in a case operated upon at St. Mark's Hospital on May 18, 1900:

The patient had had a small fistulæ, as a result of a rectovaginal abscess. The vaginal opening, which was quite small, was just within the posterior commissure; the rectal opening, which was much larger, was about an inch from the anal border. She was a very stout woman and did not present a good subject for plastic surgery. She had been operated upon by one of our best known gynecologists without success. My first operation upon her, which consisted of the usual method of splitting the sphincter, denuding the edges of the fistula and suturing this separately, was a total failure; in fact, the fistula was left larger than before. It then occurred to me to excise the rectal mucosa to a point beyond the fistula, draw down the mucosa and suture it to the skin as in a Whitehead operation for hemorrhoids. This I, accordingly, did, and excised about an inch and a half of the rectal mucosa. I then dissected the rectal mucous membrane for fully an inch beyond the cut border, so as be able to bring it down to the cutaneous border of the anus without undue traction. The mucosa was then sutured to the skin by a number of catgut sutures and with a couple of deep silkworm-gut sutures. The patient made a good recovery, having primary union throughout, and has been perfectly free from any rectal symptoms since.

I believe an important feature in the success of the method lies in the free dissection of the rectal mucous membrane beyond the excised portion, so as to be able to attach it to the cutaneous margin of the anus without any tension. The ill results at times following the Whitehead operation, in my [illegible] be possible due to the failure on the part of the operator to carry out this technic. The mucous membrane of the lower part of the rectum is, as we all know, very soft and friable, and if there be the slightest tension the sutures cut out. The result is that the mucous membrane retracts, leaving a large raw surface between it and the cutaneous border. Even when the surface does not suppurate it is very slow in healing and is likely to be followed by a marked stenosis.

I have not had an opportunity to put the method into practice since then, as, in my opinion, it ought not to be resorted to excepting for rebellious cases that have failed to be cured by the typical methods. When I carried out the procedure, as far as I knew it was original with me. Before publishing it, however, as an original method it was my intention to look up the literature to ascertain if some one else had not already resorted to a similar procedure.

I put off doing so from time to time, with the proverbial result of procrastination. But at a recent meeting of the New York Obstetrical Society (January 14, 1902), Dr. A. P. Dudley described what he designated as "Dudley's operation for rectovaginal fistula." The method, as he described it, was based on exactly the same principles as that which I had carried out in my case. He operated upon his case in July, 1901, in the Mary Hitchcock Hospital, Burlington, Vt., fourteen months after I performed my operation.

The only difference between his case and mine is that the fistula in his case was situated higher up, and he resected, as he stated, about three inches of the rectal mucous wall. His case was complicated by hemorrhoids, which he first excised according to the Whitehead method. He then excised the rectal mucosa higher up, that embracing the fistulous opening, and sutured the upper end of the mucous wall to the anal cutaneous border.

I was now determined to carry out, without further delay, my intention of searching the literature upon the subject. I found that Dr. Paul Ségond had already performed the operation in 1895, and described it in "Annales de Gynecologie et d'Obstetrique," Vol. XLIV, 1895. In Ségond's case the fistula was larger and situated higher up in the rectum than in Dudley's case. The operation was done without incising the perineum, and proved to be a complete success. To Dr. Paul Ségond, therefore, belongs the credit of priority, although Dr. A. P. Dudley and myself devised the operation independently of him and of each other. It appears to me an appropriate name for the operation would be "The Cure of Rectovaginal Fistula by Excision."

*51 Madison Avenue.

Pain in the Diagnosis of Digestive Diseases.—S. P. Scherer (*The Medical and Surgical Monitor*, March, 1902) says: In hyperchlorhydria there is pain from two to four hours after meals, burning and gnawing in character, passes away when stomach is empty, is relieved by alkaline medication or albuminous food, aggravated by acid fruits, smoking, anxiety, etc.

In ulcer pain comes on when food is taken into the stomach; tender point over seat of ulcer and to the left of the twelfth dorsal vertebra. Not so severe when stomach is empty; relieved by orthoform, 10 per cent. sol. Pure gelatin should be given every hour for protection to mucosa.

Pain in hypersecretion is paroxysmal, greatest at height of digestion, aggravated by slowly digesting foods. Pylorus is the seat of greatest pain and tenderness, frequently confounded with gallstone colic, relieved immediately by lavage, [illegible] to produce suitable [illegible].

Pain in gastroptosis is not severe, often associated with hyperacidity. More of a dull heavy feeling, increased by eating or drinking, splashing sounds well marked soon after eating or drinking. Stomach feels well when empty. Cure: mechanical support by abdominal binder, food finely masticated, and rest at least one hour in twenty-four hours, strengthen flabby muscles.

Pain in cancer is constant or paroxysmal, influenced by the pathological conditions, more severe when stomach is full of stagnating food. Sharp, lancinating or distention, may follow around the course of intercostal nerves, patient constantly aware of some gnawing disturbance, rapid emaciation, relieved temporarily by opiates.

In hypersthenic gastritis pain and tenderness are over entire stomach, aggravated by foods and stimulants, relieved when stomach is empty, aggravated by overexertion and excitement. Indications: lavage with one-half of one per cent. of argentum nitrate. Hot applications over stomach after meals, rest.

These diagnostic points are only of importance when taken in connection with careful clinical history, physical and chemical examination of patient, as the symptomatic treatment alone of digestive diseases is usually unsatisfactory both to patient and physician.

A Harmless Local Substitute for Ergot.—This substance to which W. Fischer gives the name of "metroglycerin," is a preparation containing 60 per cent. of glycerin in a combination which has the specific action of the concentrated agent, but is free from its toxic properties and can be rendered sterile. A series of experiments is reported showing its freedom from undesirable local or systemic by-effects, while clinical experience justifies the assertion that it is the ecbolic *par excellence*. In abortion 50 c.c. and in labor 100 c.c. are introduced into the uterus by means of a sterile syringe and catheter, and used in this way during the past five years the author has found it universally safe and reliable. It is indicated in all conditions of uterine inertia in abortion and labor as well as for the induction of abortion and premature labor when necessary.—*Monatsschrift für Geburtshülfe und Gynækologie.*

Report of Experiments with Yellow Fever Fomites at Las Animas Hospital, Havana.—John W. Ross conducted his experiments in the city of Havana itself, in buildings similar in construction and material (*mamposterra*) to those occupied by people of the poorer classes of the city—damp, poorly lighted, badly ventilated, with floors on the level of the ground. They were conducted at the season of the year when the dreaded scourge is at its worst and does its most deadly work. The facts obtained from the procedures is in accord with the convincing experiments conducted by the Yellow Fever Commission of 1900, and the conclusion reached is the same, namely: "Yellow fever is not conveyed by fomites, and hence disinfection of articles of clothing, bedding or merchandise, supposedly contaminated by contact with those sick with this disease, is unnecessary."—*New Orleans Medical and Surgical.*

Immigration Record Broken.—While the exact returns of the immigrants which came through the Immigration Building on Ellis Island in the month of May have not been computed, it is known that all records have been broken. About 85,000 was the figure for May. This is 12,000 higher than any figures which are remembered by the old immigration officials. On one day during the month more than 7,500 immigrants were received on the island or arrived at New York city. The number actually landed and examined was only 6,088, a little more than 200 below the record. The total of immigrants who were examined and who arrived last week, including those on the steamers *Celtic* and *L'Aquitaine*, was over 24,000.

INVESTIGATIONS INTO THE CAUSE OF CANCER.

THE April number of the *Journal of Medical Research*—devoted to a consideration of the investigations undertaken at the Surgical Department at Harvard Medical School into the cause of cancer—has been published at a very opportune time. Never in the history of cancer has the disease excited the widespread attention, both among scientific men and the general public, that it is arousing now. The increase of cancer in every land, its loathsome nature, the personal interest taken in the subject by eminent people, and the baffling mystery of its origin, have all combined to invest the malady with a peculiar importance. This sentiment has been strongly expressed of late, by the donation. on the part of rich men, of large sums for the especial object of providing every facility to investigate the origin of cancer.

Scientists have been busy for many years in attempting to reach this end, and with some degree of success. The parasitic theory of the origin of cancer for some time received full credence in many quarters; indeed, some were, and are still, fully convinced that ample proof had been afforded that cancer was caused by parasites. Latterly, however, a considerable amount of doubt has been evinced as to the validity of this theory, and many now hold with Stiels and others that the origin of cancer is due to degeneration of the nuclei of the epithelial cells. While Hansemann attributes the cell inclusions in cancer to (1) Degeneration of cells and anomalous secretion; (2) Phagocytosis; (3) Invagination; (4) Abortive and pathological mitosis; (5) Special organs of the cell, archoplasm or paranucleus; (6) Extra-cellular hyaline drops (Russell's); (7) Cancer cells themselves.

The *Journal of Medical Research* for April consists of articles on "Coccidium Infection of the Rabbit's Liver," by E. E. Tyzzer; "Molluscum Contagiosum," by Charles J. White and W. H. Robey, Jr.; "Culture Experiments with Malignant Tumors," by Oscar Richardson; "Four Pathogenic Torulæ," by Joseph D. Weis; "The Relation of Blastomycetes to Cancer," by Edward H. Nichols; "Cell Inclusions in Cancer and in Non-Cancerous Tissue," by R. B. Greenough.

These articles, the result of careful research, practically cover the whole ground, and the conclusions arrived at by all the writers are of a negative nature, but are decidedly in opposition to the parasitic theory.

Dr. Edward H. Nichols summarized as follows: It has been claimed by the adherents of the theory of the parasitic origin of cancer that (1) A proliferation of epithelial cells analogous to the lesions seen in cancerous tumors can be produced by certain well-known protozoa—nodules caused by the coccidium oviforme; (2) Certain skin lesions characterized by epithelial cell proliferation are due to the action of a so-called protozoon—molluscum contagiosum; (3) Blastomycetes are constantly present in human cancers, and are the cause of the lesion; (4) By experimental inoculations of animals with "blastomycetes," true epithelial or cancerous nodules can be produced; (5) Finally, the well-known endocellular bodies seen in the protoplasm of cancer cells have a definite morphology, are "parasites," and the cause of cancer.

As a result of the work pursued by the investigator in research during the past year, and published in the *Journal of Medical Research*, it is concluded that: (1) The lesion produced by the coccidium oviforme is essentially a process of chronic inflammation, and is not analogous to the lesion seen in cancer; (2) The lesion in molluscum contagiosum is characterized by certain changes in the epidermis, is not due to the action of a protozoon, and is not analagous to cancer; (3) The so-called "blastomycetes" ("saccharomycetes") of Sanfelice and Plimmer are torulæ; (4) The lesions produced by these "blastomycetes" (torulæ) are essentially nodules of peculiar granulation tissue, are not cancerous, nor in any sense true "tumors; (5) Blastomycetes are not constantly present in human cancers; (6) The peculiar bodies seen in the protoplasm of cancer cells are not parasites, nor the cause of the lesions, but probably are, in part at least, atypical stages of the process of secretion by glandular epithelium.

It will be observed that the whole trend of the investigations made at the Harvard Medical School is absolutely opposed to the parasitic theory of the cause of cancer.

The articles are destructive of the belief that microorganisms have anything to do with the production of cancer in man. One of the most important conclusions reached is that the "blastomycetes" are not feasty substances at all, but torulæ, the difference being that the latter do not produce spores, and do not develop any mould-like vegetation.

It is not in the least to be expected that these pronouncements will be regarded as final, but will doubtless be warmly combated by the upholders of the parasitic theory of the origin of cancer. Nevertheless, the investigators at Harvard have done excellent service, in their efforts to get at the truth concerning the cause of cancer, and the several papers are valuable contributions to the literature on the subject.

THE IMPROVEMENT OF MARKET MILK.

INHABITANTS of cities are beginning to appreciate the importance of being able to procure pure milk. They have reached this stage of reasoning by practical experience, and by education. At one time an unaccountable indifference prevailed with regard to the quality of the milk, or rather it might be said that ignorance of the bad effects consequent upon the consumption of contaminated milk existed. However, the community at large, taught by physicians and sanitarians as well as by observation, has come to the conclusion, that it is not only desirabsolutely necessary to the preservation of health that the milk supply should be as pure as possible. Nevertheless, concerned as the majority of the population may be of this need, ideas as to the best means of effecting its fulfillment are extremely vague.

Therefore the suggestion of a feasible plan for the improvement of market milk should be welcome. Such a plan has been proposed by Mr. R. A. Pearson, M. S., Assistant Chief of Dairy Division, U. S. Department of Agriculture, and which he has published in pamphlet form.

The suggestion made is that a milk commission should be formed, consisting of a responsible body of citizens who are interested in an improved milk supply.

The Commission should select and secure the advice and assistance of four experts—a veterinarian, a physician, a bacteriologist, and a chemist—all more or less familiar with the conditions and peculiarities on dairy farms.

The Commission should send to each dairyman who supplies milk to the city a circular naming all the particular conditions which should be found on every farm where milk is produced for city use, and announcing that when any dairyman notifies the Commission that he is fully conforming to the conditions specified, or endeavoring to do so, his dairy will be inspected, and, if it is found to comply in letter and spirit to all the requirements, his name will be placed upon an "approved" list, and he will receive an official endorsement in the form of a certificate.

The requirements are far too lengthy to transcribe here, but they would seem to cover every possible detail with respect to ensuring a supply of uncontaminated milk.

Mr. Pearson is strongly in favor of awarding certificates to dairies conducted in an approved manner, holding that it may be very useful to one who sells milk by assisting in securing fair prices and new trade, for many of the best class of milk users would value the assurance thus given.

Regarding dairy laws and regulations, Mr. Pearson says: Thirty-one States have laws of more or less detail referring to milk for city use, and practically all large cities have special regulations or ordinances relating to milk. These laws and regulations have, undoubtedly, done a great deal of good, and their benefits should not be underestimated. But experience has shown that in some respects they are deficient. For example, of what special benefit are milk laws to the person who wants milk of high quality and as pure as it can be produced, or not at all. There are many such persons. Laws do not require the production of that kind of milk, and if they did require it the probability is that they could not be enforced. This is fully appreciated by those who have charge of their enforcement. The laws usually state that milk shall contain at least 3 per cent. of fat; sometimes they prescribe more and sometimes less. Frequently preservatives are prohibited. Legal force is directed principally toward carrying out these requirements. They usually prohibit the sale of impure or adulterated milk or milk from diseased cows, but they do not define these requirements, and naturally opinions differ upon them. Sometimes they provide for the inspection of producing dairies, but it is seldom that any great part of them are visited and such visits are often only visits; a little extra attention is usually given to the dairies within city limits. The result is that in many places no attempt whatever is made to enforce sanitary conditions, unless the attention of the authorities is called to an especially flagrant case, which may be dealt with under the general sanitary laws. More satisfactory results of laws may be expected, but they will doubtless come very slowly. The laws may be depended upon to assist materially in raising the average quality of milk, which is extremely desirable, but there will always be a great variation in the units that go to make the average, and consumers who are not reliably posted run the same chance of purchasing from a dairy that is below the average as from one that is above. The laws themselves and the manner in which they are enforced are in great need of improvement. Under present conditions they not infrequently have more effect in teaching consumers to avoid milk than in inducing suppliers not to violate their provisions. The public read so many startling reports of diseases among dairy cows and of prosecutions of dishonest milkmen that they do not know what dairyman or dealer to trust, therefore they protect themselves by going without milk. There are thousands of such persons in every large city and hundreds in every large town. The statement of a milk inspector that the worst dairies have been improved or abolished is not satisfactory to them, for they do not care to run the risk of getting milk even from those next to the worst. As long as they have no way of knowing where they can procure pure milk they will use as little as they can.

Both pasteurization and sterilization of milk have their drawbacks, for it is by no means certain that by either method all the harmful bacteria are destroyed. In fact, most of the prominent authorities declare that pasteurization and sterilization are to a great extent, ineffective processes. This being so, it is eminently desirable that absolutely natural milk, the product of healthy cows, should be easily procurable.

Mr. Pearson claims that such milk can be reliably obtained by adopting the plan described above. There would seem to be no reason to doubt his statement, and cities and towns would do well to appoint milk commissions based upon the foregoing suggestions.

THE NATIONAL GUARD HOSPITAL CORPS.

A striking example of the use of an efficient ambulance corps was given at the accident which occurred during the parade in honor of our French visitors on Tuesday, May 27. A bridge, built over an excavation made for building purposes, was crowded with a mass of people of both sexes, and gave way under the weight, precipitating the greater part of its occupants more than thirty feet, among a quantity of débris.

The hospital corps attached to the National Guard fortunately chanced to be near at the time of the accident, and its members were mainly instrumental in extricating the fallen and injured.

The majority of those hurt had been brought up to the street, and were being conveyed to the nearest hospital on litters and in Troop C's Red Cross ambulance when the first city ambulance appeared on the scene.

The manner in which the hospital corps went about their work was a proof of their thorough training, and afforded an excellent object lesson on the utility of such organizations in emergencies.

Sir Henry Thompson on Automobiles.

To the ordinary pedestrian who cannot afford to indulge in the luxury of automobiling, the motor car is a nuisance, often an abomination. This is especially the case in crowded cities, and the automobile, driven, as it too frequently is, at a reckless speed, is a source of danger to life and limb, and the cause of shaken nerves to many a harmless citizen. There should be strict laws regulating the speed of these machines within reasonable limits in thickly populated localities.

As to the motor car, considered from the health standpoint, there has until recently been little said. Sir Henry Thompson, however, has just published a book on motors, in which he appears as an enthusiastic advocate of this form of exercise. He declares that the easy jolting which occurs when a motor car is driven at a fair speed over the highway conduces to a healthy agitation; it "acts on the liver" in much the same way as horseback exercise acts. He says the exhilaration which accompanies driving in a motor is particularly helpful to people who are somewhat enervated. Furthermore, the action of the air on the face, and the continual inspiration of fresh air, tend to promote sleep, and is an excellent aid in the prevention of insomnia.

To dwellers in cities the automobile is of great benefit, as it enables them in a short time to reach the fresher air of the country. It is difficult to exaggerate the necessity for those who live in the densely populated parts of cities and large towns to take every possible opportunity of breathing the purer air of the country. The air in towns is impregnated with carbon. It is also, in dry weather, loaded with dust, a great part of which is composed of dry and pulverized horse manure. In wet weather, fluid manure, from the same source, is absorbed by and then exhaled from the road or wood pavement, with similarly injurious effects.

These impurities are practically absent from the air of the country, and so access thereto is one of the great benefits which may be derived from the use of the automobile.

All this is doubtless true, and the automobile has proved a great boon to the overworked city man. Nevertheless, the fact cannot be denied that the automobile has been and is still abused.

Used in moderation, and as a form of healthful recreation, the exercise is worthy of all the praise that has been heaped upon it. But, on the other hand, when the motor car is made the means of senseless speed tests, and when traveling at seventy miles an hour seems to be the object of all up-to-date automobilists, the practice is hurtful to the health of the travelers, and a menace to the community at large.

Automobile exercise in moderation is good, but when practised to excess is bad for all concerned.

The Superabundance of Medical Men.

There are few countries of the civilized world in which the supply of medical men is not more than equal to the demand. Probably Russia is almost the only exception. In Great Britain competition among doctors is painfully acute, and a similar statement applies with equal force to France and Austria. It is notorious that the evil is more accentuated in the United States than in any other part of the globe, and that, unless steps are taken to restrict the output, the situation from being serious will become absolutely alarming.

In Germany the aspect of affairs, viewed from the physician's standpoint, can hardly be termed encouraging, for the practisers of the healing art increase and multiply out of all proportion.

Mr. Oliver J. D. Hughes, United States Consul-General to Germany, has recently sent to the Assistant Secretary of State at Washington some quotations from an article which appeared in *The Aerztliche Central-Anzeiger*, with regard to the position of medical men in Germany. It appears from the article in question that in 1880, on an average, one physician was counted for every 3,400 inhabitants; in 1900, there was one for every 2,000, and, in all likelihood, in 1906, the proportion will be one to 1,850 people.

Not only is the present position of medical men in Germany unsatisfactory, but their prospects for the future are even more gloomy.

The total number of physicians in Germany now amounts to 28,500, only 6 per cent. of whom are in the employment of the State The remaining 94 per cent. get no pension, are not freed from municipal taxes, and most of them are compelled to pay a considerable house rent.

It is computed that, up to 1906, about 500 physicians will die every year, while 1,350 young physicians will come from the medical schools, so that their number will be increased by 860 yearly.

The German physician's lot does not compare favorably with that of the American. He has to study for at least six years and a half, generally for a longer term than this, and must spend more than 12,000 marks ($2,856) on his studies. After all this work and expenditure of money it is stated that more than one-half of the German physicians make less than 3,000 marks ($714) a year.

From 1887 to 1896 the increase of the population of Germany amounted to 115 per cent., while the number of physicians during the same period augmented by 63.8 per cent.

The Prevention of Enteric Fever among Troops on the March.

War would be robbed of one of its worst terrors if any effective means could be devised whereby the water used for the soldiers' consumption might be rendered reasonably uncontaminated. In hot countries, during or after a long march, drinking is a necessity, and if the soldier is unable to procure sterilized water when he requires it, he will infallibly quench his thirst with whatever kind of water is within his reach, despite all efforts of his officers to the contrary.

The need is to have a plentiful supply of water, together with a satisfactory apparatus for ridding it of its noxious properties.

The *British Medical Journal* of May 3 has an interesting editorial bearing on the subject, in which is described a plan about to be adopted in the British Army:

Special water carts, of the Lefebvre pattern, are to be attached to columns, in the proportion of two to each 1,000 men. These water-carts of French design are of special construction. The type of cart adopted by the British Army has a large square tank of wrought iron, holding 150 gallons, surrounded by an insulating jacket. A special feature of the cart is that it has at the back a small compartment holding an iron cylinder, in which are placed asbestos bags, packed with a mixture of charcoal and potassium permanganate; this is the "clarifier;" it is provided with a suction pipe worked by hand, by which water from a stream, pond or river can be forced through the charcoal into the reservoir. All the parts can be taken to pieces for cleaning and the cart, which is mounted on two wheels and weighs, when full, one ton, is drawn by mules. These carts are to be used for collecting the water. The water thus collected will then be passed through an apparatus for sterilizing it, either by heat or by filtration, and delivered into ordinary water-carts, which will be used only for receiving this 'safe water.'"

For sterilizing by heat it is intended to use an apparatus of the type of the Waterhouse-Forbes water sterilizer, the great advantages of which are accurately described in "Munson's Military Hygiene." The particular form of water sterilizer, however—the writer in the *British Medical Journal* goes on to say—is really a detail in the scheme, and its application must, to some extent, depend upon local circumstances; the essential point is that water-carts from which men are supplied with water for drinking should never receive any other water than that which has been so treated as to satisfy the medical officers that it is safe.

The construction of the special water-cart described above would seem to be ingenious, and if it acts as well in practice as it promises in theory, will prove a great success. Any method that will ensure a supply of water which is not calculated to originate enteric fever among troops on the march will be gladly adopted by every army in the world.

THE HEREDITY OF POETIC TALENT

Some months ago, in the pages of a prominent review, a writer of note discoursed at length on the subject of genius, its heredity, its occurrence among the different professions and callings, and its various manifestations. The conclusion was come to, that the medical profession was curiously sterile in the production of men of genius, more so indeed than any other profession. As to the soundness of these conclusions, there was at any rate among medical men, a belief that they were not well founded, and many conspicuous examples were cited to demonstrate the fallacy of the reasoning. Whatever doubt there may be as to the possession of genius among doctors, dead or alive, every one is agreed that many poets have been accorded this divine gift.

According to the *Lancet*, May 10, in a discussion opened at the Medico-Psychological Society of Paris and reported in the *Archives de Neurologie* for April, Dr. P. Chaslin referred to the subject of the heredity of poetic talent, basing his remarks chiefly on a recent publication by Dr. Mobius, which dealt exhaustively with the same topic. Dr. Chaslin and Dr. Möbius arrived at the following conclusions: first, that great poetic talents were solitary and exceptional, even amongst persons exhibiting a taste or aptitude for poetry; secondly, that the mother of a poet was always an intellectually gifted woman, whereas the son of a stupid woman was always stupid; and, thirdly, that poetic talent was hereditary and was transmitted through the mother alone. Dr. Chaslin cites numerous instances in support of these conclusions.

Francis Galton, however, in "Hereditary Genius," takes an altogether opposite view to this, and has stated positively, "in the case of poets and artists, the influence of the female line is enormously less than the male," and he supports his assertion with a "summary of relationships of twenty-four poets grouped into twenty families."

Poetic talent or genius is like inventive or literary talent, capricious, and does not pass from generation to generation as a rule. There are a few scattered instances where the child of a poet has been touched himself with the divine afflatus, but these are the exceptions. Speaking generally, the children of poets do not shine any more than the sons of inventors, statesmen, orators, social reformers make names in the same pursuits followed by their fathers. With regard to the question as to whether conspicuous talent comes from the father or mother, despite Galton's dictum, the matter cannot be called finally settled. The long-held belief that a man's talent is inherited chiefly from his mother, as Mobius asserts, will be long in dying.

VOLCANIC ERUPTIONS AND THE ISTHMIAN CANAL

Attention has already been called in some of the medical journals to the extreme unhealthiness of the country bordering on the Nicaragua and Panama routes of the projected Isthmian Canal.

Of these two routes, probably Panama bears a more sinister reputation for insalubrity than Nicaragua for the reason, perhaps, that the former has been exploited while the latter has not been touched.

The *Scientific American*, May 24, points to another menacing feature which distinguishes one of these routes. The article referred to declares that the Martinique disaster conveys a special warning to the people of the United States, on account of the seismic and volcanic eruptions which may affect the route in question.

So far as Panama is concerned, it is stated that no trace of volcanic agency can be found there, and that there is within 180 miles of the canal no volcano even of the extinct variety. Nicaragua, on the other hand, has always been a center of seismic disturbances; its route is lined with, or closely approximate to, volcanoes, some of which have shown evidence of tremendous latent energy. There have been occasions within the past century when the volcano Cosequina in the northwest of Nicaragua has been in active eruption, and earthquakes have been plentiful in the same region.

The recent appalling occurrences in the West Indies have naturally occasioned a great fear of volcanoes, and the existence of volcanoes in the immediate vicinity of the Nicaraguan route is calculated at the present time to create a certain amount of distrust of the section of the country in which it is proposed to build the canal.

There can be but little doubt that when the canal has been built along whichever route is chosen, efforts will be put forth to free the district from the diseases which now prevail, and further, that when the present dread of volcanoes has subsided, the fact that Nicaragua appears to be volcano-ridden will exert small influence on the choice of route.

American Medical Editors' Association.—The annual Meeting of this Association will be held at Saratoga Springs on June 9. The preliminary program includes the following: "President's Address," Alexander J. Stone, St. Paul; "An Evolution in Journalism," T. D. Crothers, Hartford, Conn.; "The Reciprocal Relations between Physicians and Medical Journals," Burnside Foster, St. Paul; "A Step Forward in Affairs for the Profession," C. H. Hughes, St. Louis; "The Evolution and Influence of Medical Journalism," Dudley S. Reynolds, Louisville; "International and State Medical Comity," Clark Bell, New York; "The Editorial. Its Place in Medical Literature," Frank P. Norbury, Jacksonville, Ill. The annual dinner of the association will be given in the Hotel Kensington. The secretary of the association is Dr. Otho F. Ball, Linmar Building, St. Louis.

News of the Week.

The American Urological Association will hold its annual meeting at Saratoga on June 13 and 14. This association has been formed to promote the study of the male and female urinary tract in health and disease, its membership being open to all regular physicians legally qualified to practise medicine and surgery in any part of North or South America or the West Indies. The annual meeting is held each year at the same place as that of the American Medical Association on the last day of and the day following that meeting The meetings of the New York branch, at present the only one, are held on the first Wednesday of each month except June, July, August, and September. It is permissible to read a paper before the association in any modern language, but the annual report will be published in English and Spanish. The preliminary program contains the titles of twenty-four papers. Anyone intending to present a paper, the title of which has not yet been published, should communicate at once with the secretary. The following are the officers of the association: *President*, Ramón Guitéras; *Vice-President*, Wm. K Otis; *Treasurer*, John Van der Poel; *Secretary*, Ferd. C. Valentine; *Assistant Secretary*, A. D. Mabie, all of New York city.

The Beth-Israel Hospital was opened with appropriate exercises on Sunday, May 25. The hospital is located at Jefferson and Cherry streets, in the heart of one of the most densely populated sections of the east side. The hospital has four large wards for patients, one of them a children's ward, and an isolation ward for contagious cases. Then there are ten rooms for urgent cases or private patients, an operating room, a laundry, meat and milk kitchen and sterilizing and disinfecting plants. The whole of the ground floor is given over to the dispensary department and has been arranged with a view to meet an exceptionally large demand. The waiting room is capable of seating 300 persons and the necessary consultation rooms and pharmacy are arranged with a view to providing for a service of more than 30,000 a year. The cost of the hospital, including the furnishing, will be about $225,000. Mr Harris Cohen is President of the Hospital Association, and Dr. Abram Brothers Chairman of the Building Committee. The Rev. Samuel Schulmann delivered the opening address, and addresses were also made by Borough President Jacob A. Cantor, Messrs. Jacob A Schiff, Louis Marshall, and Abraham Nelson, and Dr. Louis J. Ladinski.

Red Cross Conference.— The Seventh International Red Cross Conference, under the Presidency of General Richter, was officially opened in St. Petersburg by the Russian Minister of Justice, M. Muravieff, on May 29, in the presence of the Dowager Tsarina, and many other notabilities. A hundred delegates, from various countries, were present. A banquet was given to the delegates the same evening in the Tahrida Palace. A flattering reception was accorded to Miss Clara Barton, President of the American Red Cross.

Pasteurized Milk Depots.—Mr. Nathan Straus's summer depots, where pasteurized and modified milk may be obtained for children, were opened on June 2 for the tenth year of their existence. Following are the locations of the depots:

151 Avenue C (laboratory and depot); 241 East Fifty-ninth street; 235 West Sixtieth street; 305 East One Hundred and Fourteenth street; 65 Market street; Hebrew Institute Roof Garden, East Broadway and Jefferson street; Central Park (near the Arsenal); Tompkins Square Park; City Hall Park; Battery Park; Recreation pier foot of West Fiftieth street; Recreation pier foot of East Twenty-fourth street; Recreation pier foot of East Third street; Recreation pier foot of Barrow street, North river.

The Reception Hospital at Coney Island was reopened last week for the summer, under the charge of Dr. John Burns of the Kings County Hospital. During the summer months of last year it treated 1,300 cases.

Trouble among Hospital Directors.—Application for a writ of visitation was recently made in the Supreme Court by the attorneys for certain directors of the Austro-Hungarian Hospital, who wish to have the books of the institution and management by the resident physician-in-charge, Dr. John Guttmann, looked into. The application follows a disagreement in the board of directors. In the complaint it is charged that Dr. Guttmann and his friends have arbitrarily taken possession of the building, sent the patients elsewhere, and closed the hospital. In reply, Dr. Guttmann says that the hospital has been closed for six months owing to a lack of funds.

A Monument to Dr. Thomas Dunn English.—The Society of American Authors, of which the late Dr. Thomas Dunn English, the author of "Ben Bolt," was a member, has undertaken to erect a monument to his memory, and has issued an appeal for subscriptions for that purpose. Should any funds be left after the monument is provided for, they will be turned over to Dr. English's family. Contributions should be addressed to Morris P. Ferris, 32 Broadway.

Boric Acid as a Meat Preservative.—The German Sanitary Department, after an examination extended over a long period, and an exhaustive series of experiments, has decided that the use of boric acid or borax preparations to the extent necessary for the preservation of meat should not be permitted. On the other hand, Professor Edmund v. Lippmann stated, recently, that he had made analyses of oranges, lemons, and other tropical fruits, showing that they all contain large quantities of boric acid. The *Chemiker Zeitung*, commenting on this, asks how it is possible that the universal consumption of these fruits, containing such quantities of boric acid, could be regarded by everybody as highly beneficial to health, if, in reality, boric acid is necessarily injurious, as the Imperial Health Office asserts.

National Confederation of State Medical Examining and Licensing Boards.—The twelfth annual meeting of this association will be held in Saratoga on Monday, June 9, under the presidency of Dr. N. R. Coleman of Columbus, Ohio. Members and ex-members of State medical examining boards, physicians and educators who are interested in the cause of higher medical education are cordially invited to attend. Every State or territorial board whose duty it is to examine or license physicians intending to practise in the jurisdiction of the board, by whatsoever name it may be called, is urged to affiliate with the National Confederation, if it has not already done so. The Secretary is Dr. A. Walter Suiter, Herkimer, N. Y.

The American Medico-Psychological Association.—The fifty-eighth annual meeting of this association (formerly known as the Association of Medical Superintendents of American Institutions for the Insane) will be held at Montreal on June 17–20, under the presidency of Dr. R. J. Preston of Marion, Va. The annual address will be delivered on the evening of June 18 by Dr. T. Wesley Mills of McGill University. The secretary is Dr. C. B. Burr of Flint, Mich.

A League for the Suppression of Inoculable Diseases.—At a meeting of physicians, held at the office of Dr. J. C. Shrader, of Iowa City, on April 14, an association was organized with the object of educating the laity regarding their sexual relations so far as may enable them to avoid the widespread evils of venery which are so disastrous, not alone to the health and comfort of men and women, but of children who are innocent victims of venereal disease. The name selected for the league was "The Iowa Society for the Suppression of Preventable Diseases." The following are the officers: *President*, Dr. J. C. Shrader; *Vice-President*, Dr. [illegible]; *Secretary and Treasurer*, Dr. J. G. Mueller, all of Iowa City.

The Confederation of Members of Reciprocating State Medical Examining and Licensing Boards.—A meeting of this association was held in Chicago on May 20. Representatives from the Illinois, Wisconsin, Indiana, and Michigan boards were present, and the details for the reciprocal exchange of certificates between Indiana, Wisconsin, and Michigan were perfected upon the basis of the two qualifications passed at the January meeting of the Confederation, viz.: (1) That a license or certificate of qualification of at least one year's date and based upon presentation of a satisfactory diploma, and an examination before a board in specified branches of medicine and surgery, may be accepted at the discretion of a board in lieu of an examination, and as a basis upon which the license of a State may be issued. (2) That a license or certificate of qualification of at least one year's date, issued by a State board of registration or medical examiners based upon presentation of a satisfactory diploma and upon the recommendation of a State board of registration or medical examiners as to the reputability of the applicant, may be accepted at the discretion of a board in lieu of an examination, and as a basis upon which the license of a State may be issued. The boards of the above mentioned States meet in June and will take such action then as will result in the immediate exchange of certificates.

The following officers were elected: *President*, J. R. Currens, Two Rivers, Wis.; *First Vice-President*, J. M. Dinnen, Fort Wayne, Ind.; *Second Vice-President*, W. F. Curryer, Indianapolis, Ind.; *Secretary*, B. D. Harison, Sault Ste. Marie, Mich.; *Treasurer*, W. A. Spurgeon, Muncie, Ind.

Philadelphia County Medical Society.—At a stated meeting, held May 28, Dr. John B. Roberts reported a case of deformed nose treated by subcutaneous injection of paraffin. The patient was a man whose nasal bones had been fractured and considerable deformity had resulted. White paraffin was sterilized by heat and its solidifying point reduced to 105° F. by addition of petrolatum. The paraffin was then injected by means of a metallic hypodermic syringe, also sterilized by heat. After a little manipulation, the mass soon became hard, and a shapely nose was the result. There was little pain, and scarcely any reaction. Dr. B. Alexander reported a case in which a similar operation had been successfully performed. Dr. Moses Behrend read a paper entitled "The Dangers of Inflating the Stomach with CO_2 Gas, Its Diagnostic Value, Report of Three Cases with Autopsies." In all of these cases a sense of oppression succeeded by depression followed the consecutive ingestion of a teaspoonful of tartaric acid in four ounces of water followed by a like amount of sodium bicarbonate. In one death resulted from hemorrhage due to the rupture of a vessel in a preexisting gastric ulcer, and in the two others from distention of the œsophagus, due in the one case, to the presence of carcinoma at the cardiac orifice, and in the other to undetermined causes. Dr. L. J. Hammond read the "Report of a Case of Gunshot Wound of the Thorax Involving the Heart." The symptoms were slight, and a lesion of the heart was not suspected. Improvement apparently took place, and the patient was permitted some liberty in moving about and in sitting up. Death resulted suddenly, and post-mortem examination disclosed a penetrating wound of the apex of the left ventricle with an enormous amount of pus and blood in the pericardial and pleural sacs.

Medical Appointments in the Philippines.—The Civil Service Commission will hold an examination on June 17 and 18 to fill positions of medical inspector and physician under the civil government of the Philippine Islands. The salaries to be paid vary from $1,800 to $2,000, and the positions in some instances include quarters in addition to the salaries named. Some of the appointments from the medical examination may be made to the position of president of provincial boards of health at salaries of less than $1,000 per annum, but in these positions living expenses are usually much less than in Manila and the opportunity for outside practice greater. The examination is open to all citizens of the United States who comply with the requirements.

An Impostor.—Physicians are warned against a young man, heavily built, tall, good talker, who professes to be an agent for *Collier's Weekly*, and solicits subscriptions to this periodical, offering a three-volume history as a premium. The manager of this weekly has declared this man an impostor.

Camden (N. J.) District Medical Society.—At the annual meeting, held May 13, the following officers were elected for the ensuing year: *President*, Dr. John G. Doron; *Vice-President*, Dr. John W. Marcy; *Secretary*, Dr. Paul Mecray; *Treasurer*, Dr. Joel W. Fithian; *Historian*, Dr. H. H. Sherk; *Reporter*, Dr. Joseph H. Wills; *Trustee*, Dr. H. Genet Taylor; *Censor*, Dr. W. H. Ireland.

Obituary Notes.—Dr. T. RITCHIE STONE, of Washington, died suddenly, on May 31, of heart disease. Dr. Stone was an old resident of Washington, having been born there in the same house in which his death occurred in 1857. He received his early education in the local schools, and took his medical degree from the University of Virginia in 1884.

Dr. SAMUEL R. COCHRANE died of apoplexy at his home in Albion, N. Y., on May 25. He was a graduate of the Medical Department of the University of Buffalo in the class of 1867.

Col. EDWARD P. VOLLUM, Surgeon U. S. A., retired, died in Munich, Bavaria, on May 31. Col. Vollum was seventy-five years of age, and had been on the retired list for eleven years. He was born in New York, appointed an assistant surgeon in the army from that State forty-nine years ago, and served through the Civil War with distinction. A year before he was retired he was made Chief Medical Purveyor of the army. In March, 1865, President Lincoln breveted him lieutenant-colonel for faithful and meritorious services during the Civil War.

Dr. CLARENCE M. VAN SYCKLE died of typhoid fever at his late residence in Brooklyn on May 13. Dr. Van Syckle was born at Boonton, N. J., on June 14, 1878. He was a graduate of the public schools and of the Brooklyn High School. His professional education was obtained at the College of Physicians and Surgeons, and at the Baltimore Medical College, from which he was graduated in 1901. Since receiving his degree he had practised in Brooklyn.

Professor ADOLPH KUSSMAUL, formerly professor of medicine at the University of Strassburg, died on May 27, at the age of eighty years.

Correspondence.

OUR LONDON LETTER.

(From Our Special Correspondent.)

NURSES—PAROTID TUMORS—BACTERIA—LYMPHANGIOMA—SARCOMA OF SYNOVIAL MEMBRANES—HORIZONTAL DILATATION OF AURICLE—VICTORIA CROSSES.

London, May 16, 1902.

Nurses, like the poor, are always with us—some good, some, alas, bad; all more or less imperfect human beings. Doctors, who see most of them and are best able to judge of them, are, as a rule, content to employ the good and dispense with the services of those who may prove unequal to the immediate duty required of them. Not so the patient and friends, who, naturally, see more of the individual, and have to bear the results of failure. Current literature has so often depicted the nurse as an angel that some allowance may be made for the disappointed employer, who declares her to be a nuisance. That she has proved herself such in many households is undeniable, and that is at the bottom of her "unpopularity," which Miss F. M. Johnston admitted and tried to account for in the April number of the *Nineteenth Century and After*. I do not say that she has succeeded in explaining the fact, and think she lays too much stress on the notion that the employment tends to render the nurse indifferent or callous. There seems no more reason for a nurse to become hardened than a doctor. But Miss Johnston's admission opened the floodgate, and newspapers are having their say.

The May number of the *Nineteenth Century* contains two replies to Miss Johnston, one by Mr. Sidney Holland, the other by Miss I. Stewart. The latter—*place aux dames*—describes nurses as, "for the most part, hard-working, womanly women, with the faults that belong to other women," and, as to the special charge of indifference, she asserts that the better part of their nature and character is "developed and strengthened by contact with much suffering, the exercise of much self-denial, and a cheerful submission to duty."

Mr. Holland, as an official of the London Hospital, who is largely responsible for the management of its nursing staff, takes up the question from an institutional point of view, repudiates the charge that hospital nurses are overworked, and holds that the public expect too much of private nurses. Of course, he defends the present system, for it is a source of profit to his hospital, which sends out its nurses to private cases. Other hospitals do likewise, but the plan is open to abuse, and, on the whole, unsatisfactory. An excellent hospital nurse may often find herself out of her element in the sick-room of a private house. This would be more likely to be felt in a case in which her special abilities were not called for.

The war has opened the eyes of many to the necessity—not to dwell on the propriety—of employing more men as nurses. Nevertheless, many women who claim to be womanly are loud in their assertion that women are the fittest nurses for all cases; they claim an exclusive right to the nursing profession, and deride the suggestion that mere modesty should have a say in the matter. It is only when a powerful man becomes delirious or insane that they are willing for men to undertake the case, and then they will often prefer an untrained man to a trained male nurse. Our hospital authorities are greatly to blame in this matter. We have a certain number of men thoroughly well trained as nurses, but our hospitals will not employ them, nor will they afford facilities for training others.

Messrs. Raymond Johnson and T. W. P. Lawrence started a discussion at the Pathological Society on Parotid tumor and other endotheliomata. They showed a number of specimens, and illustrated their paper by lantern slides, and asked whether the so-called parotid tumor and others of identical structure were of epithelial or connective tissue origin. In the specimens in museums they did not find any adenomatous structure, and had come to the conclusion that they were, in fact, endotheliomata, but they had no data as to whether they arose in the endothelium of blood vessels or lymphatics. In reference to the well-defined and limited distribution of salivary-gland tumors, it was suggested that similar formations might arise in other parts of the area of distribution of the carotid vessels. Other contributions to the subject followed.

Mr. Seligmann read an account of three cases of tumors which he considered endotheliomata. Two in the soft palate and the other in the abdomen.

Drs. Rolleston and Grünbaum showed sections from four tumors (three from the cheek, one from the lip), which they classed as endotheliomata. One was typical, one was a perithelioma, and somewhat resembled a villous carcinoma. The other two, from the lip and cheek, respectively, closely resembled parotid tumors; like them, contained cartilage, and arose from endothelium living lymphatics.

Messrs. Emanuel and Nuthall read an account of six cases of growths in the alimentary tract, and showed specimens. They could trace no connection with the epithelium. In all the mucous and serous coats were unaffected. Endothelioid cells were found in the growths.

Dr. Targett was inclined to regard these specimens as cancerous, arising from the deep layer of the mucosa.

Drs. Corner and Scott showed sections from a tumor of the lip and another of the submaxillary gland, both of long standing and with fibrous capsules, and containing no vessels.

Mr. Shattock discussed the nature of a mixed tumor of endotheliomatous type, which had long been in University College Museum. It belonged to the same group as parotid tumors.

Mr. Gask showed sections of a complex papillomatous growth, probably arising from the endothelial lining of the synovial sheath of the ankle-joint, after an injury.

Dr. Payne, looking at the various cases and specimens before the society, was inclined to think parotid tumors originated in embryonal "rests." Mr. Targett leaned to the old view that they were altered gland tissue.

At a subsequent meeting of this society (May 6) bacteria were to the fore. Dr. Klein announces that he had found in dead rats sent to him from Bristol a bacillus which closely resembled that of plague, morphologically and pathologically, but differed in cultural qualities.

Drs. Foulerton and Kellas read a paper on the action of currents or discharges of high potential and rapid frequency on bacteria. They experimented by spraying the current over the surface of an emulsion in water of the organisms. They tested thus the bacillus typhosus b. coli communis, b. dysenteriæ (Flexner), b. anthracis and some streptococci and staphylococci. A proportion of the b. anthracis were destroyed in twenty minutes, and the emulsion was sterilized in forty-five minutes. The emulsion of b. dysenteriæ was sterilized in thirty minutes. In these two cases the exact lower limit had not been determined. Emulsions of the other bacteria were sterilized by exposure to the current for from ten to twenty minutes.

Dr. Bokenham reported similar experiments he had been making, and said the results varied a good deal with the conditions. Thus with a brush discharge the emulsions were all sterilized in from ten to twenty minutes, but with a condenser discharge the effect was negative; indeed, in some cases the vegetative growth seemed to be rather reinforced.

Mr. Leslie Milburn described a bacillus he had isolated from bodies of laboratory guinea-pigs dying from pseudotuberculosis. The organism resembled that obtained by Muir and Klein from the disease in birds.

Mr. Seligmann reported that he had found the fluid withdrawn from two knee-joints of cases of Charcot's joint disease complicated with locomotor ataxy, had a remarkable effect on the growth of bacteria. The fluid completely inhibited the growth of b. coli, typhosus, streptococcus pyogenes, staphylococcus albus, aureus and citreus. The effect ceased when the fluid was dilated with 50 per cent. of broth.

At the Clinical Society last Friday Mr. Spencer related a case of congenital diffuse lymphangioma terminating in lymphosarcoma after lymphangitis. The patient was a girl born with the right leg longer than the left, but it gave no trouble until, at four years old, it became inflamed. Hectic soon set in, and in three months she died. It was suggested that lymphatic-gland sarcoma would more accurately describe the disease.

Mr. Turner related a case of that rare affection sarcoma of synovial membrane. It was in the ankle-joint of a man of thirty-two who had knocked his foot against a screw two months before it began to swell.

Mr. Lockwood read an account of a case of sarcoma of the synovial membrane of the knee in a woman who had suffered in the joint for three years. The interest in the case was considerable, from the difficulty of diagnosis. It was believed, in fact, to be tuberculous, and resection was performed, but the absence of carious material or pus excited suspicion, and on examination by two pathologists independently, it was pronounced sarcoma. When first seen two points might have excited suspicion that the disease was not tuberculous: (1) Absence of muscular wasting; (2) Free and painless mobility of the joint after having been the seat of supposed tuberculous disease for three years.

Mr. Marsh, president, referred to the case reported in the "Transactions," vol. 32, which resembled these. The patient is now alive, and was in hospital lately with a consolidated lung, which, however, cleared up. He said the temperature, which led Mr. Lockwood to suppose his case [illegible] is not a [illegible] grave [illegible] [illegible].

Drs. W. [illegible] and [illegible] O[illegible] read a paper on [illegible] of the last Voyage," referring to the five cases recorded by Drs. Owen and Fenton, and one shown at the meeting in January. Of course, a complete account of the affection is at present impossible, but rather lengthy details of the cases were given. Dr. Owen had inquired [illegible] but could only hear of [illegible] other cases.

On Monday the King bestowed the Victoria Cross on Captain E. T. Inkson, R.A.M.C., for his distinguished service in the battle-field.

In Wednesday night's *Gazette* it was announced that the King had signified his intention to confer the Victoria Cross on Surgeon-Captain A. Martin Leake of the South African constabulary for conspicuous gallantry in attending to wounded in action at Vlakfontein on February 8. He was shot three times, but continued to attend to the other wounded until he rolled over thoroughly exhausted. Even then he refused water until all his wounded had been served. Such are the sort of men that Lord Wolseley declared are "not soldiers," and the Duke spoke of as "lower civilians," but to please the "combatant officers."

The Irish College of Surgeons bestowed its honorary fellowship on Surgeon-Captain Crean, who received the Victoria Cross for gallantry in the field last December.

Progress of Medical Science.

The Boston Medical and Surgical Journal, May 29, 1902.

Papilloma of the Bladder.—G. H. Washburn reports the case of a woman of forty-nine years who complained of strangury pains in the region of the bladder and urethra. These had been present more or less for three years and had not been relieved by operations previously performed for the removal of tumor of the bladder. An operation was performed and there was found within the bladder a papillomatous growth as large as a good sized hen's egg. Other smaller growths were scattered all over the bladder wall. An oval piece of the bladder wall to which the larger tumor was attached, was cut away while the small growths were removed by cautery. Recovery was satisfactory.

F. B. Harrington reports three cases of papilloma of the bladder in men. The first patient died a month after operation, the other two made a good recovery. In the first case a microscopic examination of the growth was made and the tumor was regarded as malignant because fairly satisfactory evidence was found of the presence of atypical epithelial cells arranged loosely and in columns in the submucosa, and also because of the great variability in size and shape and abnormalities in appearance of the cells.

Maurice H. Richardson removed by suprapubic cystotomy a small papilloma of the bladder characterized by an excessive hemorrhage. He advises suprapubic exploration in all cases of hæmaturia in which from the urinary examination there is reason to expect bladder tumors. Preliminary examinations with the cystoscope and the lithotrite should be made when the patient's strength is good. Exploration by suprapubic cystotomy is indicated early in the history of hemorrhage, for then the patient's powers of resistance are best, and the tumor is more easily and thoroughly extirpated. Prolonged delay is responsible for most of the failures, immediate and remote, that follow suprapubic cystotomy for bladder tumors.

Journal of the American Medical Association, May 31, 1902.

Action of Silver Nitrate and Chromic Acid in Chronic Glossitis under the Influence of the Electric Current.—M. L. Ravitch treats his cases as follows. After painting the patient's tongue with a 15 per cent solution of nitrate of silver or 5 per cent solution of chromic acid, the patient is told to hold the wet positive sponge electrode in one hand while the negative metal electrode is rubbed over the painted diseased areas for from ten to fifteen minutes, an excess of saliva is produced, and it is caught by the patient or operator holding a large piece of absorbent cotton to the mouth. Pain of which most patients are apt to complain is greatly relieved by galvano-chemical applications, the hyperæmic condition of the tongue gradually subsides, the tissues become more natural, the patches gradually fade away and the tongue assumes its healty color. From twenty to thirty applications is all that is needed even in the severest cases. Irritant condiments must be forbidden and the digestion cared for.

Rotary Lateral Curvature and Pott's Disease of the Spine.—D. W. Marston discusses the differential diagnosis and rational treatment of these two conditions. In the former he advises the following: (1) Mechanical support and proper gymnastic exercises are to be combined. (2) The exercises are to be taken while the patient wears the support. (3) The apparatus is removed while the patient sleeps. (4) Where the deviation is more than half the diameter of the vertebræ no unyielding support is permissible. (5) After absorption of bone has taken place the primary curve cannot be eradicated, the "cure" being in the establishment of compensating curves, which maintain the equilibrium of the spinal column. In tuberculosis of the spine on the other hand we must remember the importance of the following: (1) Fixation and extension are to be employed. (2) The existence of abscess and ulceration do not contraindicate the immediate application of proper immobilizing apparatus. (3) Forcible correction of deformity is advised only in selected cases. (4) Finally, the success or failure in the treatment of either of these diseases is dependent largely upon the intelligence and willingness on the part of the patient, the care and help of the parents or friends, and prolonged watchfulness at regular intervals on the part of the surgeon.

Surgical Conservatism of the Ovaries and Fallopian Tubes.—Edwin Ricketts makes a plea for greater conservatism in the surgery of the pelvic organs. He states that in cases of congenital stenosis of the Fallopian tubes causing sterility, that are diagnosed only after the abdomen has been opened for other reasons, dilatation of the tubes often results in a cure. In healthy Fallopian tubes associated with a thick tunica albuginea, a free longitudinal and transverse incision, followed by dissection of the same promises a cure for these anteoperative distressing symptoms of pain and general lassitude along with an exhausted nervous system. With a thickened tunic, through which can be plainly seen protruding a few or a number of small flattened or round cysts, the ovary containing them may be retrodisplaced and held firmly by bands of adhesions. To free the same by carefully dissecting them away and puncturing them often means success. He who always resorts to hysterectomy for fibroids, whether large or small, should not be regarded as a conservatist in pelvic surgery. Myomectomy in many instances, under such circumstances, may be chosen as the operation of election. Large myomas are successfully removed to save the uterus and the opposite Fallopian tube and ovary.

Medical News, May 31, 1902.

The Smallpox Problem.—Ernest Wende says that it should be made indispensable that health officers qualify by a course of study in sanitation before being eligible to office. Success in combating this disease depends on an enlightened system of isolation, quarantine and disinfection, based upon a thorough understanding of the origin and transmission of the disease, the duration of isolation and quarantine to be regulated by the period of incubation and the period of infection. The enforcement of these regulations should be accomplished by members of the police department rather than by doctors or sanitary inspectors. The orders should emanate from a central authority and their execution should be prompt. The patient should be at once removed to a suitable hospital, no distinction being made.

A Contribution to the Subject of Infant Feeding.—S. Henry Dessau holds that by far the simplest, cheapest, and best food for daily use is a fair average quality of cows' milk diluted with water, the amount varying with the age and digestive capacity of the child. The "top milk," the upper part of milk that has stood in a vessel at a temperature not above 60° F., for from four to six hours, is sometimes preferable. The proportion of fat to proteids in this milk is much greater. Because cows' milk contains no sodium salts, while human milk does, a pinch of common salt or phosphate of sodium is added, also a heaping teaspoonful of raw cane sugar to the quart. This mixture is placed in a double boiler, with cold water in the outer vessel, and left on the fire ten minutes after the water has begun to boil. The greater the dilution of cows' milk, the easier of digestion the curd becomes. For babies under three months of age it is generally well to use equal parts of water and milk. For older babies one part of water to three of milk is usually a good proportion. If barley or oatmeal gruel is used, it must be cooked for at least one hour and dextrinized by the addition of diastase.

The Bacterial Pathology, Symptomatology, Diagnosis, Treatment, and Quarantine of Tonsillar Inflammations. William G. Bissell discusses first, follicular tonsillitis simplex. This affection is without known microorganismal origin. Positive diagnosis can be made only by cultural methods, which in this instance will reveal the staphylococcus pyogenes aureus and albus to the exclusion of other organisms. Treatment is simple and prognosis excellent. Calomel internally, glycerin, with chloride of iron on the tonsils, is indicated. The next class of diseases shows the Klebs-Löffler bacillus. Quarantine should be established. Antitoxin should be administered. If the membrane be dense, a local application of Löffler's solution, 10 per cent. nitrate of silver, 10 per cent. protargol is of value. Dotell's solution, or Seiler's tablets in solution, assist. The prognosis of tonsillar and pharyngeal diphtheria is excellent if the disease be recognized early and if the proper treatment be followed.

Another class of diseases is inflammation of the tonsil, in which the streptococcus pyogenes is present to the exclusion of other organisms. The treatment from the local standpoint is the same as that of diphtheria. Constitutionally, diphtheritic antitoxin does little or no good. Antistreptococcus serum seems to be of value. There should be some quarantine measures. The next class considered are those inflammations of the tonsil due to the micrococcus of sputum septicæmia. The treatment is about the same as for the infection by the streptococcus pyogenes, except that no antitoxic substance has as yet been discovered. Tonsillar infections due to the oidium albicans are combated by local stimulative alkaline washes and a general tonic treatment. The writer then speaks of disinfection.

Philadelphia Medical Journal, May 31, 1902.

Two Cases of Folie du Donte.—John H. W. Rhein reports these cases. The first patient was a woman, twenty-four years of age. Her symptoms had begun when she was sixteen years old. She was afflicted with the desire to repeat whatever she did or said. She had the fear that she had committed a sin, the character of which she could not define. There is no history of insanity in the family. The second patient was a woman of forty years, who suffers from the fear of being contaminated. She feels this fear especially after handling her handkerchief. These cases illustrate a disease which has been described under the title of folie du donte. The writer thinks that it may be concluded that folie du donte, *i. e.* a train of symptoms in which doubt and fear of contact with external things predominate, may be a manifestation of neurasthenia, with the same prognosis as this disease, or that it may be a distinct form of mental disorder of degenerative type, having some relation to neurasthenia, but incurable, with remittent symptoms, occurring mainly in women, and beginning about the menophania. The symptoms of this affection may be observed also in certain forms of insanities, such as hypochondriasis, melancholia and in syphilitic inanities.

On Cystoscopy, Its Value and Dangers.—Frederic Bierhoff states that, in addition to using a reliable cystoscope, much importance attaches to the source of the electrical current. This may be either a dip-battery, storage-battery, or the street current as used for incandescent lighting. A proper rheostat must be connected with the source of the current to regulate the supply which reaches the cystoscope. Examination is more difficult in the male than in the female. It is wise in determining the question whether the urethra is of sufficient caliber to admit of the insertion of the cystoscope, to employ for the purpose of emptying the bladder, a catheter which is slightly larger than the instrument to be used. The bladder should be capable of a sufficient degree of distention for satisfactory illumination. In the male usually 150 c.c. of fluid suffice, while in the female 200 to 250 are better. There is a certain routine of examination which gives the minimum of discomfort and the maximum of information. It is: After turning on the current and being satisfied that the light is of sufficient intensity to permit of clear vision, the lower margin of the sphincter is first examined, then the trigone, and the ureters; these are located and their character and activity, as well as the character of the urine noted, and then the lower posterior wall of the bladder is examined. Then one of the lateral quadrants in its entirety is completely and carefully examined. Then the upper and anterior wall and, finally, the other lateral wall. Cystoscopy is not always easy, as there may be strictures or spasmodic contraction of the compressor urethræ. The dangers of cystoscopy have been much exaggerated; disasters are due to faulty technique, or carelessness on the part of the examiner. Where a proper degree of asepsis is observed, it should be no more dangerous than catheterization or the passage of a sound. The more intricate and delicate manipulations should be left to the expert, but the simple cystoscopic examination should be within the grasp of every general practitioner.

American Medicine, May 31, 1902.

The District of Columbia Cancer Record for Twenty Years.—Clarence A. Smith draws the following conclusion from these statistics: (1) On the basis of comparing cancer deaths with those of thirty years and over, no increase of the disease is found in the last decade over the preceding; (2) Classification of cases into accessible and inaccessible reveals practically no increase in the former, but entirely in the latter, probably the result of improved diagnosis and certification of deaths; (3) Aside from cases of the female generative organs, the sexes are equally liable to the disease; (4) The white and colored races are alike subject to cancer, the latter showing a greater increase in cases of the uterus and liver; (5) While cancer deaths during the last decade have increased over those of the previous decade by a larger percentage than those from any other disease, we are not justified in attributing this to an increase in the disease itself.

Pneumococcus Arthritis.—Rufus I. Cole considers this a rare condition. He reports several cases, and from a study of them concludes that there is a tendency to involvement of the larger joints, though small joints may also be affected. There is a tendency to the involvement of more than one joint (thirteen out of forty-one cases). There is a tendency to involvement of joints already the seat of a chronic affection. (In thirteen cases a history either of chronic rheumatism, old injury, previous arthritis or gout.) The effusion is usually purulent, but may be serous. The mortality is high (twenty-eight deaths, thirteen recoveries). The clinical features of the condition and the prognosis depend more on the septicopyemia, of which it is usually but a manifestation, than on the joint lesion itself. When recovery occurs the course is usually a long, slow one, and usually ankylosis of the joint results. The local treatment should consist in free opening and draining of the joint. The fact that in a few cases of mild infection of the smaller joints spontaneous recovery has occurred might justify one in adopting conservative methods in such cases. Considerable experimental work has been done on the artificial production of pneumococcus arthritis in animals.

Bubonic Plague.—Joseph J. Curry states that most writers divide this disease into three classes or types: (1) Pestis bubonica, or bubonic plague; (2) Pestis siderans or septicæmic plague; (3) Pulmonic plague. Bubonic plague is by far the most frequent type. There is a type called pestis minor (mild, or walking plague), with very low mortality, cases of which invariably precede epidemics. The invasion of plague is generally sudden, and is often accompanied by a chill, followed by high fever. The onset is quite similar to that of the malarial fevers. Soon after the initial fever, there appears a glandular swelling in the groin, axilla, or neck, generally in groin, The swollen gland is extremely tender. There is great mental depression. Death occurs usually in from two to five days. Absolute diagnosis of the bubonic type is made, readily and safely by aspiration of the swollen glands. It would be difficult to make a diagnosis of septicæmic plague, in the absence of other cases of bubonic or pulmonic plague, save at post-mortem. In the pulmonic type the bacilli occur in enormous numbers in the watery, bloody expectorations. Rats are very susceptible to this disease, and often die in great numbers in the course of an epidemic; flies, ants and other insects act as carriers of the plague bacilli. The first and greatest prophylactic measure is cleanliness, Rats and mice should be destroyed. Food and drink should be protected from possible contamination. During epidemics all food should be cooked.

The Lancet, May 17, 1902.

Remarks on the Subsequent History of Children Born While the Mother Was Insane.—A. F. Tredgold studies this question, using several statistical tables for the purpose. He believes that the only logical conclusions, from the facts at his command, are the following: (1) The mental and physical condition of the child is in no wise influenced by the mere fact of the mother being insane during pregnancy; (2) Neither is the condition of the child influenced by the variety of insanity, the duration of the attack, or the age of the mother, nor even directly by the number of attacks from which the mother may have suffered; but that (3) This condition is directly dependent upon the presence or absence of morbid hereditary influences.

Liquid Air as a Freezing Medium in the Laboratory.—W. H. B. Stoddart says that liquid air evaporates quite slowly when stored in the vacuum flasks used by the manufacturers. An untouched gallon evaporates from the storage flask in about six weeks. In ordinary constant use in the laboratory a gallon lasts a little longer than a fortnight. Liquid air is therefore very much cheaper than ether for laboratory purposes. Further, it acts much more rapidly than ether—about from twenty to thirty compressions of the indiarubber bulb are always sufficient to freeze the gum and the tissue [illegible] Lastly, the [illegible] When [illegible] to a good [illegible] to the country.

A Case of Rodent Ulcer of the Nose and Eyelids Treated with the X Rays.—The case is reported by [illegible] Taylor, whose patient was a [illegible] The condition has existed for some twenty years. Treatment was begun on May [illegible] A [illegible] of [illegible] was used for twenty minutes [illegible] weekly. [illegible] to four times a week. Up to about August no healing had been very [illegible] but on this date treatment had to be suspended because of the sharp reaction, indicated by a sudden appearance of a [illegible] red erythema surrounding the ulcer, attended by the destruction of the newly formed epithelium over the surface and of the surrounding epidermis, brought about, I think, by change of the x-ray tubes from one of high vacuum to one of medium vacuum. It took five weeks for the effects of this reaction to disappear, when spontaneous healing began and was very rapid, for on October 15 the ulcer had cicatrized with the exception of a small area which proved obstinate, and where an application of potassa fusa had been made six years previously. On this date treatment by the x-rays was resumed, but they were applied to this unhealed spot only for ten minutes three times weekly, the newly-formed scar tissue being specially protected from their action with double lead-foil shields. Treatment was completed by December 20. At that time there was not the slightest evidence of the disease, neither has there been any recurrence. It is interesting to note also that the conjunctiva of the everted lower lid and that of the inner canthus was covered with a smooth layer of opaque horny epithelium and no trace of the puncta remained.

A Case of Malformed Fœtus.—The peculiarities of the case are thus described by N. Erlington. The body was well developed and the lower part of the face was that of an ordinary full-time child. The frontal bones were widely separated and were flattened back so as to be almost at right angles to the face. The eyes were very far apart and the eyeballs protruded. The parietal bones were small and what should have been their upper margins were pointing almost directly backward. The occipital bone was only represented by two small strips of bone lying close to the posterior edge of the parietal bones. All the cervical and the upper five or six dorsal vertebræ were apparently wanting. The chin rested on the second piece of the sternum, the ears, which were abnormally large, lay in front of the shoulders. The back of the head and the neck was occupied by a mass of freshly formed blood-clot, which in one place had burst through the skin; there was no hair and the skin of the head was very thin. The labor occurred at full term and the mother was certain that the child was alive two hours before her pains began, which they did only three hours before the child was born. The author had to be content with an external examination, and consequently cannot say what was the condition of the brain and the spinal cord. There was nothing during the pregnancy out of the ordinary except the amount of liquor amnii, which was very excessive. He thinks that there is no doubt that the child died from the effect of pressure during parturition. The presentation, as may be imagined, was somewhat bewildering, but the progress of the labor was very rapid and the child was born with the chin presenting under the symphysis pubis without any difficulty.

The Lancet, May 24, 1902.

Improvements in the Operation for the Radical Cure of Inguinal Hernia by the Use of Some New Instruments and Gold-Wire Sutures.—J. T[illegible]ni has devised a hook for the spermatic cord, special retractors, and a spatula for depressing the floor of the wound, all of which are figured in his paper. He recommends the use of gold for sutures, as it can be drawn into wire finer than silk, and is also stronger and more flexible. The suture is fixed by twisting the ends of the wire three times. With it and with the instruments above referred to, the author is able to complete the radical operation in ten minutes. Operating in the same place and with the same assistant, out of 100 consecutive operations for the radical cure of hernia, of which not a few were of a serious nature either from their size or from adhesions or from the age of the patient, he has uniformly obtained healing in eight days without any suppuration, early or late, and without a single relapse.

Linen Sewing-Machine Thread for Ligatures and Sutures.—Arthur [illegible] J. [illegible] says that this material can be obtained everywhere, and that it is relatively very cheap. It can be easily sterilized by boiling in plain water and then stored in methylated spirit. It is remarkably strong, and ties a most [illegible] knot. It is easy to work with, and runs through the eye of any suitable needle easily, having been spun with special care in order to travel evenly through the sewing-machine needle. He has used several sizes, and now limits them to three, viz., No. 40, which is as thick as could be desired for the abdominal wall or ligatures of the larger arteries; No. 60, which is thinner, but still very strong; and No. 100, which is as fine as can be desired, save for a suture of the intestine. He finds it convenient to procure No. 40 as a white thread, No. 60 as red, and No. 100 as black. He has prepared it by simply boiling it for an hour in ordinary water and then keeping it in spirit. A little of the dye comes out of the finer threads in boiling, but does not appear otherwise to alter the thread, which can be boiled over and over again without rotting it. It is well borne by the tissues, and altogether seems to be an ideal article for the purposes named.

A Contribution to the Study of Tropical Abscess of the Liver.—Ten cases are reported by B. J. Graham. Special attention is called to the complicating abscesses in the pleural cavities and lungs. If extensive pleural adhesions have formed the patient is saved from very great danger. Two important diagnostic points with reference to the existence or non-existence of adhesions are the following: (1) The upper level of the dulness caused by a liver which is enlarged upward is, speaking generally, considerably lowered when the patient is placed on his left side. If, however, the lower part of the pleural sac is obliterated by adhesions, this does not occur, because the lung cannot be sucked down into the pleural sinus by the falling away of the liver—that falling away which so frequently causes pain when the patient attempts to lie on the left side. (2) In very thin people, even when the parts are normal, it is often possible, on careful inspection, to see the lower margin of the lung on the right side move upward and downward during respiration. It may sometimes be observed on the left side, especially if the spleen be enlarged, or if there be a great enlargement of the left lobe of the liver, or, indeed, any tumor in this situation, and on the right side it is more obvious when the liver is enlarged than when it is of normal size. This sign requires somewhat careful inspection for its discovery and it is only of use in emaciated or very thin subjects. If it be present, it is a certain proof that there are no adhesions in this situation, and that there is little or no pleural effusion. Persistent discharge of chocolate-colored pus from a pleural or pulmonary abscess is no positive proof that the liver abscess has not healed. A pulmonary abscess consequent on a hepatic abscess should be opened without delay, and the site of election for the incision is in the lower axillary region.

British Medical Journal, May 17, 1902.

A Note on the Operation for Removal of Malignant Disease of the Breast.—Douglas Drew has, during the last two years, removed in almost all cases the sternal part of the pectoralis major, and in the more recent cases both pectoral muscles. But it is too early yet to draw definite conclusions concerning immunity from recurrence. It makes an extensive operation more extensive, but shortens very much the time occupied in clearing the axilla. The after-condition of these patients shows remarkably little inconvenience. In many cases it does not seem greater than when the muscles have been left intact.

An Analysis of Forty-six Cases of Cancer of the Breast Which Have Been Operated upon and Survived the Operation from Five to Thirty-two Years.—Thomas Bryant believes that the interval which may take place between the primary amputation of a breast for cancer and its recurrence in the scar or second breast, when such occurs, is very uncertain. While in half the cases tabulated in this paper recurrence took place in five years or less, in the second half the interval varied from six to thirty-two years. As to the seat of the recurrence it appeared in or about the scar of the original operation in fourteen cases, in the scar and axilla in only one case, in the sternum in three cases, in the second breast in ten cases, and in five of these the scar of the first operation was also involved. The writer notes that it is not his custom to clean out the axilla in all cases of recurrent cancer, and yet his results do not suggest an inadequate operation. They show that operations for cancer of the breast when undertaken at an early period of the disease are not as unsatisfactory in their ultimate results as we have been led to believe. Even should the disease recur after the primary operation, the prospects of prolonged life without second or third operations are neither unreasonable nor unsatisfactory. When recurrence has been treated by second or third operations much benefit may be conferred. The result of operation would be much better than they now are if they could always be undertaken during the early development of the disease. Every breast tumor, neither clearly inflammatory nor encapsuled, which seems to involve gland tissue, and may therefore be cancerous, should be at once explored and removed, if found to be cancerous, with the whole gland; and recurrent growths when localized should be similarly treated. In advanced and neglected cases, where the lymphatic glands and covering integument are involved, the so-called complete operation may be called for, but its results are not by any means so likely to be as favorable as these reported by the writer, whose operation is rather between the modern operation known as Halsted's and the older one by which rarely anything more than the diseased breast itself with the skin covering, when involved, was removed. In cases of recurrence not favorable for operation, unless the removal of the ovaries can be shown in the future to be successful, the *x*-rays should be employed. The influence of the rays, to make them effective, must be maintained for several months after it has seemed to be beneficial; a three-months' course, with about three applications a week, appears to be the shortest from which any permanent good is to be expected, and this treatment is full of hope.

A Case of Premature Senility of the Uterus.—Augustus W. Addinsell reports the case of a woman, aged twenty-six years, who consulted him for sterility. She had at that time been married a year, but during all that time had never menstruated. Examination, both internal and external, revealed nothing abnormal. It is now nearly seven years since she was married, and during this period there has been no appearance of mentruation, with the exception of a slight show for one day only. She appears to be in good health, and is strong and active. She complains of heats and flushes at irregular intervals. Both ovaries seem healthy, but no cervix can be felt, merely a dimple in the vaginal roof. Bi-manually, no uterus could be made out, but the sound passed just under one inch. Inquiry into the history brought out the fact that the honeymoon had been spent in Switzerland, and within a fortnight of marriage the patient had sustained a great shock from what she feared might be a fatal accident to her husband. This occurred about the time that menstruation was expected. The nervous shock probably brought about the condition of premature senility of the uterus.

British Medical Journal, May 24, 1902.

Malignant Smallpox Fatal within Six Hours.—E. R. Coffey describes this case. The patient was a boy of ten weeks. When first seen the whole face was covered with a subcutaneous hemorrhagic rash. Besides this there was a rash slightly elevated on the surface which resembled that of measles. Beneath the jaw and around the neck and on the buttocks there were red patches, as if the surface had been touched with blood. The temperature was 101°. The child was partly unconscious and groaned as if in pain. The child had been perfectly well on the previous day, but on the noon of the day when seen it was dead. The diagnosis of malignant smallpox was made. The rapid fatality and difficulty of diagnosis made the case a most unusual one.

Case of Sporadic Cretinism, in Which a Relapse Occurred Owing to Omission of Thyroid Extract.—Arthur Hall reports this case to show that cretins should be kept under careful observation if the results of treatment are not to be spoiled. The child was first seen at fifteen months. It was just weaned and was put at once on thyroid extract. In a month the improvement was general, and in four months it was very great. In a little less than a year from the first treatment the thyroid was stopped by the parents, who thought that the child was becoming weaker. From that time the child steadily went backward. The child is now seven years old and is less a cretin and more of the child with myxœdema. The writer believes that in spite of the valuable time that has been lost by the cessation of treatment, that with judicious treatment and careful watching, the child will yet develop into a fairly useful member of society.

Myxœdema in Mother and Child.—Although the occurrence of this disease in mother and daughter may be a coincidence, still S. W. MacIlwaine thinks that it may show an inherited susceptibility of the thyroid to toxic influences. The mother had previously been in excellent health, but was suddenly seized with a persistent attack of diarrhœa and vomiting, which was followed by phlebitis. Graves' disease was diagnosed. The skin became affected, and also the hair, and small doses of thyroid were given, and in three months all of these symptoms disappeared, leaving no doubt that the case was one of myxœdema. Four years later the child was born, and when one year old was seized with dysenteric diarrhœa. She became a typical cretin, but on the thyroid treatment she recovered. The myxœdematous state was clearly secondary to some pre-existing toxic condition. It was an incidental symptom-group, not a primary disease.

A Case of Complete and Temporary Paralysis of the Limbs in a Child, Probably a Case of Recovery from the Initial Stage of Acute Anterior Poliomyelitis.—This case is reported by Judson S. Bury. The patient was a girl aged nine years. It was first noticed that the child had a chill. This was followed by fever and then her legs seemed to fail her. She became unable to move any part of her body except the head. She had no pain and no alteration in cutaneous sensibility. The knee-jerks were absent. The action of the bladder seemed to be normal. There was no history of sore throat. In less than a month she left the hospital quite recovered from the paralysis. As to the site of the lesion, the flaccid paralysis and the loss of the deep reflexes point to an affection of the lower neurons for the limbs and trunk. The absence of all sensory and of all other symptoms than paralysis indicates that the motor path was alone at fault. Just as difficult to settle as the site of the lesion, is its nature. The action of some poison seems to be the simplest explanation. Yet such a speedy recovery is remarkable. No facts were obtained which threw any light either on the nature or on the mode of entry of a supposed infectious agent. If it is assumed that a toxin did attack the lower neurons of the parts paralyzed, the rapid disappearance of the paralysis would suggest that the toxin had been quickly destroyed.

Deutsche medicinische Wochenschrif , May 8, 1902.

Acute (Trophoneurotic) Bone Atrophy Following Inflammatory and Traumatic Lesions of the Extremities.—P. Sudeck says that inflammatory lesions and traumatism of the extremities may be followed by an acute bone-atrophy, which is usually very persistent. In addition to the bone atrophy there may also be present an atrophy of the soft parts following traumatism. As a rule, all of the bones on the peripheral side of the lesion are involved in the atrophy. This atrophy is to be regarded as trophoneurotic, arising reflectively from the peripheral irritation. At first the radiographic picture, as shown by the Röntgen ray, is characteristic. The spongiosa shows the presence of a large number of small spaces, arranged in groups so that the whole has a dappled appearance. Later the cortical portions of the bone show numerous similar spaces. The most prominent symptoms are stiffness, pain and loss of motion in the affected parts. The diagnosis rests primarily upon the etiology and the radiographic picture as described above. As a rule, the prognosis is unfavorable, more or less loss of motion and stiffness prominently remaining. Under appropriate treatment, however, a few cases proceed to complete recovery. During the acute stage the affected parts should be immobilized. Just as soon as the pains subside, however, massage and exercise should be begun. Localized hot baths are also very useful in relieving the stiffness at this stage. If the massage and exercise give rise to pain, they should be discontinued, as under these conditions, additional irritation is caused thereby. It is important that a careful differentiation should be made between this condition and tubercular or syphilitic bone affections, since the treatment of the latter when applied to this form of bone-atrophy works irreparable injury.

The Abortive Treatment of Furuncle by the Means of Subcutaneous Disinfection.—A. Bidder says that beginning furuncles and carbuncles may be aborted by the subcutaneous injection of a 2 per cent. aqueous solution of carbolic acid, and also that advanced lesions may be rapidly cured in the same manner. Weaker solutions may give equally good results, but they have never been employed by the author. On the other hand, stronger solutions (3 and 4 per cent.) have frequently been advantageously used. In beginning furuncles or carbuncles the needle of an ordinary hypodermic syringe, filled with the carbolic acid solution, is introduced close to the border of the zone of inflammation and inserted in a diagonal direction until the center of the lesion is reached. A few drops of the solution are then injected and the needle withdrawn. The canal thus made serves for the exit of the main portion of the solution, which is then to be injected in the following manner: Beginning at a point on the border of the zone of inflammation, directly opposite to the place where the needle was first introduced, the needle is inserted to the center of the lesion in a manner entirely similar to that above described. The entire contents of the syringe

Diabetes Insipidus and Paralysis of the Bladder.—C. [illegible] reports a case of diabetes insipidus, during the course of which a paralysis of the bladder supervened. Careful examination failed to show any cause for the paralysis either in the central nervous system or in any other location. While it is possible that the same may have been due to an overfilling of the bladder, this supposition is not probable. The patient was forty-two years of age, and a primary degeneration of the bladder may hence be excluded. It is well known that various nervous manifestations are often present in diabetes insipidus. The etiological status of these manifestations is not certain, but it seems sure that it is identical with that of the diabetes. The occurrence of paralysis of the bladder in diabetes insipidus has not been previously reported and it is highly probable that in this case it is to be regarded as of similar origin to the frequent nervous manifestations above mentioned. Since the report of the above a similar case has been observed in a patient fifty-four years of age.

Münchener medizinische Wochenschrift, May 13, 1902.

Paranephritis and Pyonephrosis Following Furunculosis.—A. Cohn reports five cases of paranephritis, and one case of pyonephrosis, which were preceded by a furunculosis. No other cause could be discovered and the author thinks that the infecting microorganisms gained entrance through the furuncles. In the case of pyonephrosis it is certain that the infection did not proceed upward from the bladder. There are many cases of paranephritis in which the etiology is entirely obscure, and it is impossible to ascertain in what manner the infection has gained entrance. In view of the above cases, it is possible that such may have taken place through a small furuncle which has been overlooked in the examination of the patient. Increased observation along this line is greatly to be desired.

Reflex Spasms Caused by Ascaris Lumbricoides.—J. P. Naab draws attention to the pronounced nervous symptoms which may be produced by ascaris lumbricoides. The author has recently observed several cases in which the clinical picture closely resembled that of meningitis. The child was suddenly seized with convulsions and rapidly became comatose and thus remained for several hours. The diagnosis was at first doubtful, but later an examination of the stools revealed the presence of numerous worms. In all the cases the administration of santonin and calomel was followed by prompt recovery. There is evidently no relation between the number of worms and the intensity of the cerebral symptoms, since the latter were very pronounced in several cases where only one or two worms were found. From a diagnostic standpoint the presence of an excessive secretion of saliva is of much importance. In all of the cases which showed marked cerebral symptoms the secretion of saliva was so abundant during the night that it flowed in considerable quantity from the mouth. In cases where the stools cannot be immediately examined the presence of this symptom should be given great weight.

Influence of the Movements of the Diaphragm upon the Liver.—K. Walz designates as "respiratory" those changes in the shape of the liver which are produced by the movements of the diaphragm during respiration. The so-called "rest-stage" of the liver occurs at the end of expiration. During ordinary respiration this "rest-stage" is moderately prolonged and while it lasts the blood enters and leaves the liver unimpeded, the circulation in the liver vessels being very slow. The gall-bladder is lax and its contents remain *in situ*. The inspiration-stage of the first grade occurs at the end of ordinary inspiration. It is not present, however, in pure costal breathing. During this stage the blood and the bile are driven out of the liver vessels, but the [illegible]

[illegible]

Acute Dacryadenitis.—[illegible] concludes from his researches that this is an extremely rare disease. It is more apt to affect both lachrymal glands than one only, and may implicate the whole or only part of a gland. As a rule, it disappears in a few days, but it may go on to suppuration. The bilateral dacryadenitis is more apt to resolve, while the unilateral is more likely to suppurate. As a rule, it originates in some infection already existing in the organism, but it may arise from various causes.—*Giornale Internazionale delle Scienze Mediche*, April 30, 1902.

A Contribution to the Treatment of Aneurysms by Gelatin.—Claudio Mancini reports two cases which, while they cannot be regarded as conclusive, demonstrate that gelatin is absorbed, that it coagulates the blood, that it is not dangerous, and that it is certainly a valuable auxiliary in the treatment of aneurysms. It does not, of course, have the slightest effect upon the cause of the arterial dilatation, but it is to be used in combination with measures directed to that cause. In the case of patients who are apparently unable to tolerate subcutaneous injections it is probable that the substance can be advantageously administered in the form of enemata.—*La Riforma Medica*, May 2, 1902.

Paranephritic Hæmatic Cyst.—This case is reported by Walther. The patient was a young woman of twenty-two years who was referred to him with the diagnosis of perforating appendicitis. The patient presented the appearance of one suffering from internal hemorrhage. Chloroform was administered and in the renal region there was palpated a tumor the size of a fetal head. Lumbar incision revealed a large hæmatic cyst which contained a liter of blood and clots. The cyst was attached to the upper border of the right kidney. It was excised, the wound was drained and recovery took place. It was examined histologically and proved to be a paranephritic cyst.—*La Médecine Moderne*, May 7, 1902.

The First Symptoms of Deafness.—Castex enumerates certain symptoms, which he says are characteristic of beginning deafness. In the child there is often noticed an air of distraction, which is really due to bad hearing. Again the child will often listen with the head obliquely tilted. In the adult it is often noticed that a question addressed to him will have to be repeated. Many times the individual affected first discovers his infirmity at the theater because he notices that in order to hear he must occupy one of the front seats, or he hears the music better than the talking. Again others are not able to follow general conversation. Certain patients with tympanic sclerosis hear well over the telephone. The voice of the deaf patient is often a sigh. Some old people hear better from a distance than nearer, or they will hear a whispered voice better than a loud one, because the affected organ has lost the ability of accommodation and perception.—*Le Bulletin Médical*, May 17, 1902.

A Case of Exophthalmic Goiter Simulating Pulmonary Tuberculosis.—A. Peguiner reports the case of a man twenty-five years old who became emaciated, had a severe cough, fever, suffered from profuse sweats, and from digestive disturbances. There was no hæmoptysis, the appetite was excellent, and both the stethoscopic signs and the results of bacteriological examination were negative. The beginning of the illness was sudden, following a violent emotion; there was tachycardia, intense carotid pulsations, but a weak radial pulse, and a slight hypertrophy of the right lobe of the thyroid gland. There were present the characteristic tremor of goiter, irritability, and the signs of Graefe and of Buzzard-Charcot. A milk and vegetable diet was ordered. Alcohol, tea, coffee, and tobacco were forbidden. Every other day a shower-bath with water at 45° F. with massage. Every morning, theobromin was given and at every meal bromhydrate of quinine. Complete rest of body and mind, and a sojourn in the country in a climate of high altitude was ordered. In four or five months the patient was decidedly better. The writer does not consider the results of surgical treatment always encouraging.—*Journal des Praticiens*, May 17, 1902.

Grippal Hemorrhagic Cystitis.—M. A. Breton reports three cases of this nature. The first patient was a woman about fifty years old. Four or five days after the first symptoms of the disease, the urinary troubles suddenly began. Pain was strictly localized to the vesical region, and was both spontaneous and elicited on pressure. Polyuria, vesical tenesmus, a burning sensation during micturition and finally hæmaturia appeared. There was neither sugar nor albumin in the urine. The hæmaturia persisted for three days, but finally yielded to rest and treatment. For twelve days the signs of cystitis lasted. The upright posture or walking aggravated the symptoms. At the end of about nineteen days, the cure was complete. The second patient was a woman of sixty-five years. The hæmaturia lasted for eight days and was very abundant. The fact that this patient could not stay in bed accounted for the violence of the attack. The third case was a woman of thirty-four. The hæmaturia lasted for about nine full days, because she was not able to stay in bed from the first. Treatment of these cases consists in rest in bed, milk diet, emollient drinks, ergotine, hot vaginal douches, suppositories of opium and belladonna for the pain and tenesmus. Benzoate of soda relieves the cystitis.—*Gazette des Hôpitaux Civils et Militaires*, May 13, 1902.

American Journal of the Medical Sciences, May, 1902.

The Unilateral Occurrence of Kernig's Sign as a Symptom of Focal Brain Disease.—Joseph Sailer believer that Kernig's sign may occur as a symptom of focal encephalitis, and in this condition may be present upon only the opposite side of the body. Sometimes it is associated with spastic paresis of the leg upon that side. In these cases there may be a persistent tonic spasm of the flexor muscles of the arm, which, however, does not resemble Kernig's sign in its mechanism. The most reasonable explanation of Kernig's sign that we possess at present is to ascribe it to an irritative lesion of the pyramidal tract that diminishes but does not destroy its functional activity. It is obvious that it is not a lesion of the meninges, but of the subjacent nervous substance that causes the occurrence of Kernig's sign. Practically, all cases of leptomeningitis are associated with a more or less severe degree of encephalitis. As far as the writer has observed, however, the occurrence of the sign in the course of a typical case of encephalitis has not been recorded.

Localization of the Mental Faculties in the Left Prefrontal Lobe.—Charles Phelps states that it is immaterial, so far as it concerns a control of the mental faculties in the prefrontal region. Whether the function of this lobe is one of coordination or one of inhibition, or whether it is a direct control of mental, moral and emotional phenomena comparable to the control of mobility in the motor areas, or whether it is a control of sensori motor processes. It is simply a question of topography, entirely independent of psychological considerations. The writer believes that: The more absolutely the lesion is limited to the left prefrontal lobe the more positive and distinctive are the symptoms of mental default. The integrity of the mental faculties remains unimpaired in the right frontal lesion, though it involves the destruction of the entire lobe, or even extends to the entire hemisphere. The exceptional instances in which seemingly opposite conditions exist are always reconcilable, on more careful examination, with the assertion of an exclusive control of the mental faculties residing in the prefrontal region of the left side. The writer adds that if the same nature and degree of proof which is deemed sufficient for the localization of other cerebral functions may be accepted in case of the mental faculties, their center of control has been established.

The Causes and Varieties of Chronic Interstitial Pancreatitis.—Eugene L. Opie says that chronic interstitial pancreatitis is slightly more frequent in males than in females. Two-thirds of the total number of cases occur between the ages of forty and sixty years. The most frequent cause of the disease is obstruction of the duct of Wirsung, due to pancreatic calculi, to biliary calculi in the terminal part of the common bile-duct, or to carcinoma invading the head or body of the gland. Duct obstruction may be followed by the invasion of bacteria, which take part in the production of the resulting lesion. Ascending infection of the unobstructed duct of Wirsung may follow an acute lesion of the duodenum or of the bile passages, and may cause chronic inflammation In cases in which there has been a history of long, persistent vomiting, chronic diffuse pancreatitis may be found at autopsy, and is, probably, the result of an ascending infection of the gland. General or local tuberculosis is occasionally accompanied by chronic diffuse pancreatitis, affecting chiefly the interstitial tissue of the gland. Chronic interstitial pancreatitis is not infrequently dependent upon the same etiological factors, notably alcohol, which produce cirrhosis of the liver, and in about one-fourth of the cases the two lesions are associated. Following duct obstruction and ascending infection the lesion, affects, principally, the interlobular tissue, only secondarily invading the lobular tissue and sparing the islands of Langerhans. Diabetes results only when the lesion is far advanced. Accompanying the so-called atrophic or Laennec's cirrhosis of the liver, the pancreas is at times the seat of a diffuse chronic inflammation, characterized by diffuse proliferation of the interacinous tissue, which invades the islands of Langerhans. A similar lesion accompanies hyaline degeneration of the islands of Langerhans and the condition known as hæmochromatosis. Interacinar pancreatitis is usually accompanied by diabetes mellitus. When diabetes is absent the lesion is of such slight intensity that the islands of Langerhans are little implicated.

The Lateral Chain Theory of Ehrlich as Explanatory of Toxins, Antitoxins, Bacteriolysins, and Hæmolysins.—F. P. Gay states that Ehrlich has conceived each cell as possessing, in addition to its nucleus, multitudes of atomic "lateral chains" or "receptors," each with its affinity for a certain assimilable substance. The toxin unit must be considered as more than a simple body; it possesses at least two parts, a "haptophore" group, which unites it to the cell receptor and a "toxophore" complex, which is the poisonous element. Excess of toxin-elective "receptors" cumbers the cell, and they are eventually thrown off into the circulating blood, where they form the antitoxins. When "circulating receptors" or antitoxins are present in the blood the haptophore group become anchored and never reach the cell, which accounts for the neutralization of the action of toxin by antitoxin. Toxins are "uniceptors," that is, they have only one uniting arm, the haptophore group. Bacteriolysis depends on two elements: A specific body acquired by immunization which is not destroyed at 55° C., and a substance present in all normal sera, destroyed by heat or by standing. A hæmolytic serum contains two substances, to which Ehrlich gas given the names of "immune body" and "complement." The immune body has two affinities, a stronger one for the red blood cell, and a weaker one for the complement. Red blood corpuscles contain a united immune body. The immune body having two uniting processes is an "amboceptor." The complement resembles in its constitution and action a toxin; it has a haptophore group, which unites with the immune body, and a "zygomatic complex," which acts on the red blood cells saturated with immune body in a manner partly toxic and partly fermentative. The complement can unite with red blood-corpuscles only in the presence of the immune or intermediary body. Just as the inoculation of toxins gives rise to antitoxins, so inoculation with "hæmolysins" gives rise to antihæmolysins, which are more complex, however, being composed of "anticomplements" and "anti-immune bodies." There is reason to suppose, although the heating of hæmolysins destroys the action of the complement, that in reality it is not wholly destroyed but forms a "complementoid," which can form anticomplements. This concept of Ehrlich's gives a rational basis for serum therapy as we have it, and suggests by analogy the problems of the serum therapy that may arise.

The Etiology of Infantile Paralysis.—Alfred M. Gossage states that, from present evidence, it is impossible to arrive at any definite conclusion as to the exact nature of the disease. Clinical records are strongly in favor of at least two, and probably three or four, definite diseases, being included under the term anterior poliomyelitis: (1) One in which the paralysis comes on suddenly without previous ill-health; (2) One in which the onset of the paralysis is preceded by general symptoms, such as fever, vomiting, pain in the back, etc.; (3) The disease occurring in the epidemic form; and (4) Adult poliomyelitis. The three last-mentioned may possibly be forms of the same disease which may sometimes occur sporadically, and at other times in the form of an epidemic. Occasionally cases occur sporadically which are like the epidemic cases, the disease having spread to the nerve centers in the brain and to the peripheral nerves, and in some of these even death has ensued. In spite of the fact that a purely vascular lesion (hemorrhage into the gray matter of the cord or thrombosis) would best explain these striking cases where the onset is absolutely sudden, without any other sign of ill-health, we are compelled to regard such a cause as improbable. Of the other two possible ways by which the cells in the vencord lesion might be looked upon as a local inflammation or a primary degeneration of the nerve cells, it is impossible at present to quite ignore the latter. An acute degeneration of the nerve cells might be brought about by some poison circulating in the blood which might be formed by the growth of the microorganisms which are the causes of such diseases as scarlet fever, or by the growth of a microorganism which is specific to infantile paralysis. Such a primary degeneration is a possible cause for some cases of infantile paralysis, but the view seems to be open to [illegible]. The one objection [illegible] from the post-mortem examination is that among the [illegible] there are some of a [illegible] in the ventral horns. There is no direct evidence of the [illegible] of a specific organism for this disease, [illegible], but the clinical aspects and the post-mortem appearances are strongly in favor of this theory. It is probable that the organism associated with anterior poliomyelitis is specific to this disease and is not concerned in the [illegible] of any other morbid condition. Since there seem to be two or more different diseases included under the name of infantile palsy, there would probably be two or more specific organisms. It is impossible to go beyond this at present.

Bulletin of the Johns Hopkins Hospital, May, 1902.

Syphilitic Disease of the Cerebral Arteries.—F. C. Goldsborough reports the results of autopsies on a case of syphilis. There was shown to be predominantly an affection of the vessels, the meninges and central nervous substance being relatively little involved. The lesions consisted in thickening in the walls of the vessels, which were histologically gummata with the characteristics of gummata in other situations. These gummatous lesions were most advanced in the adventitia and were generally accompanied by proliferation of the intima in a corresponding locality. From this it would appear that the process probably begins in the adventitia. It is on account of its characteristic histological appearance as specific in its nature as the tuberculous change in the vessels in tuberculous meningitis, and is not to be confused with the ordinary arteriosclerosis.

Paracolon Bacillus.—Richard P. Strong reports the single case of infection with paracolon bacillus which has been seen at Manila. The body was observed forty-two hours after death. There was considerable post-mortem change and gas in the subcutaneous tissues. The hospital record at Santa Cruz, where the patient had died, stated that there had been no departure from the ordinary type of typhoid fever. Gwyn has reported a case of infection with the paracolon bacillus in a patient with all the clinical symptoms of typhoid fever. Cushing has reported a case of paracolon infection, the organism being obtained from an abscess of the rib following an attack of prolonged fever resembling typhoid. The serum in both these cases agglutinated the organism. No serum reaction was tried in the present case. So it cannot be said whether or not the organism was a post-mortem invader. There were no macroscopic lesions of the intestine to serve as a portal of entry. No other cause of death, however, could be found. Although the report is incomplete from the circumstances surrounding the case, the writer deems it worthy of being recorded.

The Effect of Certain Poisons on Inorganic Ferments.—Henry C. Jones states that the inorganic ferments are preparations of finely divided metals, such as platinum, gold, silver, iridium, etc. The metals are obtained in this finely divided condition by dipping two wires of the metal in question into pure water, and passing a direct electric current from one wire to the other through the water. The metal from the wire [illegible] is torn off in a state of such fine division that it remains suspended in the water in the form of a solution. These solutions of the metals are not true solutions, and in order to distinguish them they have been termed pseudo-solutions or colloidal solutions. Solutions of starch, albumin, and the like are analogous. The colloidal solutions of the metals have some remarkable properties which seem to resemble in many respects the properties of the organic ferments. A colloidal solution of platinum accelerates the oxidation of alcohol to acetic acid in the presence of the oxygen of the air, as well as the organic ferment *mycoderma aceti*. Finely divided iridium decomposes calcium formate into calcium carbonate, carbon dioxide, and hydrogen in the same manner as certain bacteria. The analogy between the action of the finely divided metals and ferments holds also for diastatic phenomena, such as the inversion of cane sugar. The finely divided metals do not enter into the reaction which they effect. Substances which act by means of their surface alone, without entering into the reaction, are known as catalyzers, and such reactions are termed catalytic. Experiments have shown that the colloidal solution of platinum can recover from the poisonous action of [illegible], provided the poison is not too concentrated. Bredig does not claim that there is any strange identity between the metals and the enzymes. But he believes, from the great number of analogies, that the colloidal solutions must be considered in many relations at least as inorganic models of the organic enzymes. The writer refers the action of the colloidal solutions of the metals, the enzymes, and catalyzers generally to the surface energy possessed by these substances. In this way we have an important step in the solution of the nature of catalysis, which underlies so many processes of both living and dead matter.

Book Reviews.

Psychology, Normal and Morbid. By Charles A. Mercier, M.B., F.R.C.P., F.R.C.S. London: Swan, Sonnenschein & Co. New York: The Macmillan Co.

This comprehensive treatise on psychology has, from the first page to the end, the freshness of originality, principally because the subjects therein discussed are considered from a point of view very different from that of other writers. The book has been written mainly, it would seem, for those interested in the subject of insanity, but it will be found instructive and suggestive to him who is not particularly concerned with the study of [illegible] of the insane but who is in pursuit of general culture.

The contents of the volume are a brief and rather unsatisfactory discussion of Sensation; Thought, under which are discussed abstraction, faults of thinking, axiomatic reasoning, belief, faults of belief and apperception; Volition, Memory, Pleasure and Pain, and Subject Consciousness.

The chapters devoted to Reasoning are particularly worthy of note. The author has striven to prove that the Syllogism is not the sole form of reasoning, and that it is, indeed, but a subordinate mode of axiomatic reasoning. The subject of belief and delusion is discussed in an attractive and scholarly manner. The writer states that in the section on Memory he has endeavored to clear up the ambiguities which have made the term one of nebulous meaning. We regret to say that success has not crowned his effort, for unless it be the section on Pleasure and Pain there is no more unsatisfactory chapter in the book.

Although it is impossible here to enter into an analysis of Dr. Mercier's work, we wish to record our opinion of its value and of its merit. The time is not far distant when a course in psychology must form a part of the medical student's studies. In the meantime the student who wishes to lay a solid foundation for the superstructure to be constituted by his future experience, can do no better than to study the volume under review.

Morphinism and Narcomanias from Other Drugs. Their Etiology, Treatment, and Medicolegal Relations. By Dr. T. D. Crothers. Philadelphia: W. B. Saunders & Co. [illegible]

This small volume is written in a somewhat [illegible] style. Selections from the table of contents are: The History of Morphinism, Opium Taking, Its Prevalence and Diagnosis, Treatment of Morphinism, Alcohol, Cocainism, Drug Habits, Mania, [illegible] Tobacco, [illegible] and Chloroform, [illegible] and [illegible].

Some of the author's [illegible]. In speaking of treatment he says: "Pleasant [illegible] which can [illegible]. In such [illegible] the stimulating [illegible] of a stranger [illegible] does much [illegible] will. The surroundings, with the central purpose of removing the morphine, will encourage general effort on the part of the patient. This idea should be made dominant at the beginning."

"The question of restraint is dependent largely on the condition of the individual." It is indeed. And the condition in this state must be one which shall justify two examiners in lunacy in certifying to the insanity of the individual, otherwise the *slightest* restraint is illegal. The author talks about putting morphinists in asylums as if it were possible to do it.

The so-called slow method of withdrawing morphine is the one which the author seems to favor. Treatment after withdrawal of the drug is spoken of in some detail.

The author's views, as herein expressed in reference to some of the comforts of life, are not likely to be taken very seriously. "The continuous and excessive use of tea may be considered not only an active cause of serious neuroses, but also a prominent symptom of psychosis, which may merge into many and complex disorders." We should like to be informed of the name of the neurosis, and ask what psychosis has "the continuous and excessive use of tea" as a prominent symptom. "There can be no doubt that the use of tobacco is poisonous." "It is an interesting study to know how far the tobacco habitué is impaired mentally, and how far he could be called responsible for his conduct and his thought." It is indeed. How far Tennyson, John La Farge, and the greatest financier of the age, or of any age, J. P. Morgan, all habitués of tobacco, are impaired mentally, would be an interesting study—for one who is mentally impaired. How far Mark Twain could be called responsible for his conduct at Albany, last winter, when he appeared in behalf of the osteopaths, has given the reviewer much concern. Now, it is apparent, and the answer is, Dr. Crother's former and distinguished townsman was not responsible—it was the weed! The author says that persons who use tobacco to excess "are of faulty memory, and both sight and hearing are equally depressed, and their statements can scarcely be depended upon in matters requiring great accuracy." When an author allows himself a free rein in this fashion, it seems, to an unprejudiced reader, that he might back it up with some other evidence than his "I said it."

The Drug Habits and Their Treatment. By T. D. Crothers. Chicago: G. P. Engelhard & Co.

A brochure of 80 pages, an abbreviation of the volume reviewed above, evidently intended for the layman.

Gynecological Pathology: a Manual of Microscopic Technique and Diagnosis in Gynecological Practice for Students and Physicians. By Dr. Carl Ohil, Privat-Docent, Berlin. Translated and Edited by Samuel Myllis Bandler, M.D., Adjunct Gynecologist to the Beth Israel Hospital, New York. Illustrated by one hundred engravings. Pp. XV–237. New York: William Wood & Company, 1901.

This little book must prove of great practical value to gynecologists, as it covers a subject which is treated somewhat superficially in the larger manuals of pathological anatomy. Introductory sections on technique are followed by exhaustive descriptions of the histology of simple erosion and commencing epithelioma of the cervix uteri. The sections on the nominal and pathological anatomy of the endometrium are especially good. The changes during menstruation, uterine and extra-uterine gestation, are clearly described and figured. Endometritis, glandular and hypertrophic, diffuse hyperplasia receive thorough treatment. Neoplasms are considered briefly, but clearly, especially carcinoma, sarcoma and deciduoma. Chapter V, on the tubes, is most interesting and instructive. Tubal gestation is exhaustively discussed, while the results of inflammation are treated at considerable length. The important chapter on the ovaries is introduced by a short description of the normal histology. The sections on oophoritis are too brief, but neoplasms are treated at length, with the exception of dermoids. A full description of the latter growths, however, appears in Part III, on embryology. It is impossible, in a brief notice, to do justice to the many commendable features of this work. Attention is called particularly to the number and beauty of the illustrations, which are not only artistic, but are such as are seldom seen in the ordinary textbooks on gynecology. These alone, aside from the valuable text, render the book a distinct help to the student and practitioner, to whom we cheerfully recommend its perusal. The translator has done his work in a scholarly manner, and deserves no little credit for his efforts as editor of the American edition.

The Practical Medicine Series of Year Books, comprising two volumes on the year's progress in medicine and surgery. Issued monthly under the general editorial charge of Gustavus P. Head, M.D., Professor of Laryngology and Rhinology, Chicago Post-Graduate Medical School, Vol. IV. Gynecology, edited by Emilius C. Dudley, A.M., M.D., Professor of Gynecology, Northwestern University Medical School; Gynecologist to St. Luke's and Wesley Hospitals, Chicago, with the collaboration of William Healy, A.B., M.D., March, 1902. Pp. 212. Chicago: The Year Book Publishers.

The name of the distinguished editor of this useful little book is a sufficient guarantee of the care and discrimination exercised in the selection and arrangement of the ample material at his command. With a few unimportant exceptions, we find little to criticise. It may seem to the attentive reader that too much space has been allotted to abdominal surgery, in view of the editor's comment in the preface that "plastic work has shown a tendency to become a lost art." Surely the past year has witnesed some valuable additions to minor gynecological surgery. The chapter on pelvic infection is quite comprehensive. Chapter VIII, on uterine tumors, is the longest of all, and contains a lucid description of the editor's method of uniting the broad ligaments after removal of the fibroid uterus. The accompanying drawings are admirable, but the question naturally arises: "Is not the technique made a little too easy?" Celiotomists will at once infer that there must be many cases in which exact apposition of the stumps is impracticable without undue tension. We do not wish to be hypercritical, but it would seem as if fifteen pages were too many to devote to the author's own device. We miss any reference to the original work, which has, during the past year, been done by the Germans in the study of ovarian pathology—especially of dermoids. The editorial comments are brief and to the point, showing a most commendable conservative tendency. Only one who has had experience in translating and condensing into a few lines lengthy, and often obscure, articles from foreign journals can appreciate the labor entailed in preparing such a year book as the one before us. We doubt not that no small degree of credit is due to the collaborator for his work. The index, typography and binding are worthy of praise.

A Handbook of Appendicitis. By A. J. Ochsner, M.D., Professor of Clinical Surgery, College of Physicians and Surgeons, etc., Chicago: G. P. Engelhard & Co., 1902.

This small volume records the author's experiences with appendicitis, and it consequently exhibits a good deal of the personal element. An attempt has been made to systematize and epitomize the subject, and the result is fairly satisfactory. We cannot say that any long-felt want is filled by the appearance of this book, but it is satisfactory as far as it goes.

The Perverts. By William Lee Howard, M.D. New York: G. W. Dillingham Co.

"Love, however obfuscated in the gloomy umbrage of ethics or in the obmutescence of patristic senility, is the conscious but uncontrollable action of physical attributes governed and stimulated by unconscious psychic forces." These "weedy, sedgy, spumy statements are an effort at detruncation of a purely lycanthropic condition arising from false ascetic pietism"; but despite delapidated detruncation disastrously debilitating him, "Leigh rushed to the bar and in a smothered voice sessile with words called for whiskey." He was "the pitiable, pusillanimous, progeny of the decayed, delapidated dregs of a former vital and equilibrated cell-protoplasm, the inevitable, invariable incarnation of the *damnos a hereditas*."

These lines are not a transcript from the archives of a lunatic asylum—at least they are not so far as the reviewer knows. He has copied them from a book called "The Perverts," which, we regret to say, is written by a member of the medical profession. Viewed as a story, the book is incoherent. From the standpoint of literary execution, it is execrable; and as an example of bad taste in subject matter, it stands at the head of the list.

Ophthalmic Myology: a Systematic Treatise on the Ocular Muscles. By G. C. Savage, M.D., Professor of Ophthalmology in the Medical Department of Vanderbilt University, author of "New Truths in Ophthalmology," ex-President of the Nashville Academy of Medicine, ex-President of the Tennessee State Medical Society. Sixty-one illustrative cuts and six plates. Published by the author, 139 North Spruce street, Nashville, Tenn. Printed by Gospel Advocate Publishing Company, Nashville, Tenn. 1902.

This volume of 589 pages is of convenient size, well printed and fairly well illustrated. Chapter I treats of the "fundamental principles of ocular motions," discussing the various phases of the subject in a systematic, logical manner. Orthophoria is discussed in Chapter II, the different methods employed and instruments used to determine the power of the extrinsic muscles of the eyes are fully and clearly described. Then follow chapters of the heterophorias, the chapter on cyclophoria occupying thirty-three pages. Strabismus is discussed under the generic term Herotropia. A chapter is devoted to the consideration of "paralysis and paresis of the ocular muscles" and one to the "muscles of the iris and ciliary body." In the consideration of chorea, epilepsy, catalepsy and neurasthenia the author may, perhaps, have exhibited a degree of enthusiasm, and have expressed belief in the causative effect of eye strain that would be considered extreme. The work bears evidence of much study and a careful analysis of the subject given. The discussion is full even to the point of repetition. There are few questions in ophthalmology that give the practitioner more concern than anomalies of the eye muscles, and oculists will heartily welcome any unbiased attempt to elucidate it. The book is well worth careful perusal.

Society Reports.

AMERICAN GYNECOLOGICAL SOCIETY.

Proceedings of the Twenty-seventh Annual Meeting, Held at Atlantic City, N. J., May 27, 28, and 29, 1902.

The Society convened in the Ballroom of Hotel Rudolph, under the Presidency of Dr. Seth C. Gordon, of Portland, Me.

An address of welcome was delivered by Dr. Philander A. Harris, of Paterson, N. J., which was responded to by President Gordon.

A Case of Wandering Spleen Packed in the Pelvis, Complicated by Typhoid Fever; Splenectomy, with Recovery.—Dr. Thomas A. Ashby, of Baltimore, who reported this case, drew attention to the anatomy and function of the spleen. He said it has been influenced by bodily ailments, the organ being large in the well-nourished and small in the poorly fed individual. In 1897 [illegible] recorded nineteen cases of splenectomy, with fourteen recoveries. These cases were reported by eighteen different surgeons. Sixteen were observed in women and three in males. In properly selected cases there was no doubt that the spleen could be removed with as good results as those which followed the removal of the uterus, the ovaries, or kidney.

The chief interest in his case was from the standpoint of diagnosis. The patient, a young woman, had lived all her life in a malarial section of country, and had had repeated attacks of malarial fever. She had contracted a malarial spleen which, from its increased size and weight, had exercised such traction upon the suspensory ligaments as to permit the spleen to wander down into the pelvis, where it became impacted behind the uterus and filled the pelvic basin. How long it had remained in this position there was no way of determining. In the meantime she became infected with the typhoid organism and developed typhoid fever. In the initial stage of the disease her temperature took a high range, and pelvic pains were soon felt. Her family physician, being called in at once, palpated the abdomen, and finding a large mass in the pelvis, and, along with this, marked tenderness and high temperature, concluded that he had a large inflammatory tumor to deal with. At this time there were no typical symptoms, and there were no typhoid cases in her family or neighborhood. He at once brought the patient to the hospital for treatment. At the time of the first examination the physical signs were markedly those of an inflammatory mass in the pelvis. There was pain on pressure, a doughy sensation to the touch, and the skin over the region of the tumor was so red and shiny that the surface indications were those of a suppurating mass ready to break through the skin. When anæsthetized the following morning the physical signs had markedly changed, and Dr. Ashby's diagnosis, before opening the abdomen, was that of an ovarian cyst or inflammatory tumor. He determined to make an incision to find out the true character of the condition and to remove the same. As soon as the incision was made, the spleen was discovered, and its removal at once decided upon. The enlarged size of the organ, length and weakness of its ligaments, made an attempt at its restoration and attachment to its normal position a physical impossibility. The only safe course was to remove the organ, and this was done without the least difficulty, as its pedicle was not larger than one's little finger at the point of its attachment under the diaphragm. It was ligated in section and the stump well covered with peritoneum. The subsequent behavior of the patient's temperature could not be accounted for until the typical typhoid reaction was obtained some six or seven days after the operation. From that time on the typhoid condition was regarded as the primary disease and was treated accordingly. The abdominal section presented no features to occasion the least alarm. Patient ran the regular course of the fever, and her convalescence was uneventful. Her health since her recovery had been better than prior to the attack of typhoid fever.

Dr. I. S. Stone reported a case of splenectomy, with recovery. He thought there was no longer any danger from hemorrhage in properly selected cases of splenectomy.

Dr. Wm. T. Howard said that splenectomy had been done three times successfully in Baltimore by Dr. Kelly. In each case an incorrect diagnosis was at first made.

Dr. Lapthorn Smith detailed a fatal case of splenectomy.

Dr. A. Palmer Dudley had seen three cases of enlarged spleen, in two of which splenectomy was performed by himself, the third case having been operated upon by another practitioner. One of his patients died, while the other recovered.

Dr. J. Wesley Bovée reported two cases of splenectomy, with one death.

Dr. Joseph E. Janvrin had removed a [illegible] spleen which weighed seven and eight pounds. The operation was rapidly done, but the patient died from what he considered [illegible] or surgical shock.

The Medical Side of Gynecology.—Dr. Edward W. Jenks, of Detroit, said that there was a medical side to gynecology which could not be ignored, for a special training, together with a thorough knowledge of general medicine, were prerequisites for the making of an ideal gynecologist. Fully one-half of the women seeking advice and relief from disorders peculiar to their sex were suffering from some deranged condition of the eliminative organs, as shown by constipation or defective elimination of solids in the urine. Even where there were lesions of the pelvic organs no relief from distressing symptoms could be secured until the underlying constitutional causes of pain and general poor health were first ascertained and removed. There were many derangements of the system which closely resembled diseases of the pelvic organs. Pain in the back, the commonest complaint of women, might be due to coccygodynia, neuralgia, or chronic malarial toxæmia, or other constitutional causes; pain in the abdomen, sometimes attributed to the ovaries, might be due to habitual constipation or to an atonic condition of the large intestine.

He was convinced that some of the medical schools were responsible for the neglect of medical gynecology. Surgical technique was taught in all its refinements, but symptomatology, differential diagnosis, and the treatment of diseases of women amenable to medicinal remedies could not receive adequate attention in the brief time devoted to them, if one judged by the results. The glamour of gynecological surgery had obscured the commonplace, but equally important, study of gynecological medicine. He made an eloquent plea for the medical side of gynecology, and urged that it be not relegated to obscurity in our zeal to advance gynecological surgery. He entered his protest against so many calling themselves gynecologists who ploughed only in one furrow of the field of gynecology, while the field itself was only a part of the great domain of medicine and surgery.

Lacerations of the Cervix Uteri and Pelvic Floor.—Dr. W. L. Burrage, of Boston, read a paper on this subject in which he made a plea for their more careful study, their diagnosis and treatment. He said the glamor of successful abdominal surgery had left the less dangerous and less showy plastic surgery in the background. Lacerations of the cervix and pelvic floor merited a more careful study than they had received; that if they were repaired early, fewer major and mutilating operations would be called for later; that the normal conditions were the ones the gynecologist should endeavor to restore, and until he was successful in doing this no attempt should be made to improve nature. Emmet gave the principles underlying repair of lacerations of the pelvic floor to the profession in 1883. These had been generally accepted as correct, and as yet no one had proved them to be erroneous. He urged the members of the society to stand by these principles and to devote their energies to perfecting details of operative technique rather than to invent or advocate operations which involved principles diametrically opposed to those of Emmet.

He had operated for laceration of the cervix two hundred and one times, and for lacerated perineum and pelvic floor a hundred and sixty-two times.

Symposium on Retrodisplacements of the Uterus.—Dr. Matthew D. Mann of Buffalo, N. Y., discussed the etiology, pathology and symptoms. He believed that the round ligaments were important factors in holding the uterus in place, and that they acted in the manner pointed out by Kellogg. If the ligaments be stretched, the uterus falls behind the center of gravity, and the round ligaments are not able to pull it far enough forward, so that intraabdominal pressure falls on the posterior wall, with every effort to increase backward displacement. Weakening of the pelvic floor, relaxation of the pelvic outlet as the result of child-bearing, with or without rupture of the perineum, will allow the uterus to sag downward, and the fundus to fall backward. Relaxation of any of the supports of the uterus tends to backward and downward displacement of the uterus, and if the ligaments and pelvic floor are relaxed, then, eventually, there will be prolapse to a greater or less extent, dependent upon the amount of relaxation. He spoke of the uterovesical ligament as having considerable influence in the production of uterine displacement. He mentioned other factors which caused the uterus to become displaced backward, one of which was rupture of the perineum, which enables the vaginal walls to come down. If these came down, with cystocele or rectocele, then the vaginal wall, dragging upon the cervix, pulls the organ downward, and tips it over backward.

In displacement of the uterus the circulation and nutrition of the organ are interfered with, so that in a short time the woman would get a chronic congestion, with thickening and enlargement of the connective tissue of the uterus. This might be called, for want of a better term, chronic metritis.

Another cause of displacement of the uterus was laceration of the cervix, which allowed the organ to sink down into the pelvis, to turn slightly backward, the displacement going on from bad to worse. He had seen two cases of displacement of the uterus, one following whooping cough in an adult, the other from straining at stool. In the latter case the uterus was forced outside of the body from constant straining at stool, although the hymen was intact. He then mentioned the symptoms of the retrodisplacement of the uterus and among them he spoke of backache, bearing-down pains in the pelvis, etc. He did not believe that every case of posterior displacement of the uterus caused symptoms, but the majority of cases of backward displacement did cause symptoms. A woman with a backward displacement of the uterus would not continue to be well. She might be well for the time-being, but eventually she would suffer. He did not believe a backward displacement of the uterus could exist for any great length of time without the woman suffering more or less. Besides the symptoms familiar to the gynecologist he thought there were a great many reflex symptoms. A woman with a retrodisplaced uterus might suffer a great deal from reflex symptoms without the presence of pelvic symptoms. He cited cases in point.

Non-operative Treatment of Retrodisplacements of the Uterus.—Dr. F. H. Davenport of Boston, Mass., read a paper with this title. The paper takes up three points: First, the methods of non-operative treatment; second, the indications for their employment, and, third, the results.

The only important method of non-operative treatment is that by pessary. Twenty-five years ago it was practically the only method, and for that reason it was developed to a remarkable degree, not only as regards the variety of displacements, but also the numerous forms of pessaries devised for their relief. Massage, electricity and general tonic treatment cannot properly be called methods, but are merely adjuncts. The choice, then, lies between treatment by operation and that by pessary. With the development of surgical procedures, that by supports was thrown into the background, and neglected. There are cases, however, which are well adapted to the pessary treatment. Such are, first, cases of simple retroverted uterus without complication, which have presumably lasted only a short time; second, retroversion following childbirth; third, cases complicating neurasthenia as a result, where operation is inadvisable until the patient's health is built up.

The pessary treatment is not applicable to cases in young girls where local treatment of any kind is inadvisable, to cases complicated with lacerations, or to cases of long standing, where secondary changes in the circulation of the uterus have followed. Many of these which should be operated on refuse operation and choose the pessary. What, then, are the chances of cure? The author's own statistics have shown that of all cases treated by pessary about one-third are cured either anatomically or symptomatically by the use of a pessary for from one to two years. In selected cases the showing would be far better. Such success, however, presupposes close study of the case, care in the selection of the pessary, and constant supervision while it is worn.

The only displacements which need correction are prolapse and retrodisplacements, and the latter may be usually corrected by one of two varieties of pessaries, the Langford and the Albert Smith. The treatment by pessary, therefore, while it should be scientific, is simple.

The Alexander Operation.—Dr. Clement Cleveland of New York, in a paper on this subject, described the Alexander operation in detail. Although usually performed for retrodeviations of the uterus, he has found it useful in the cure of forward displacements. The selection of cases, however, is very important. In cases where adhesions exist, it is better to follow some of the other methods or resort to the vaginal route. In cases where the Alexander operation is not indicated, he prefers the operation devised by Dougal Bissell, and styled by him "internal shortening of the round and broad ligaments," with which the writer has had many good results.

To obtain the best results from the Alexander operation, a pessary should be worn before, and for two months after, the operation. It is also advisable that the patient should wear one for a few months after confinement. The patient should be kept in bed for three weeks after the operation, and the dressings should be changed daily. The main point in the performance of this operation is to reach the external ring with a clean cut from the surface. To a beginner the great stumbling block is the mistaking the superficial fascia for the aponeurosis of the external oblique. The doctor believes that by including in the first suture the pouch of the peritoneum or infundibuliform process, it not only strengthens the attachments of the ligaments, but adds to the support of the uterus. Sterilized iron-dyed silk is recommended to hold the ligaments.

Hernia, as a result of this operation, is rare, and when met with, is due either to faulty technique or suppuration. The chief causes of failure are (1) Suppuration in the wounds, and (2) The too tightly tying of the ligament sutures.

In comparison with other methods, the writer prefers the Alexander operation for an uncomplicated case of displacement. In his opinion, the vaginal method of operation should be confined to women who have borne children.

Suspension of the Uterus.—Dr. Hunter Robb of [illegible]. Olive, in speaking of the advantages, disadvantages and results of suspension of the uterus, [illegible] that [illegible] are not [illegible] the [illegible] procedure being [illegible]. Before we are able to speak with authority as to the results we must have more accurate data, which can only be obtained by a more rigid classification and a subsequent analysis of sufficiently large series of (1) Uncomplicated cases of suspension. (2) Those cases of suspension in which other pathological conditions are present, but in which the [illegible] of the suspension [illegible] operation. (3) Those cases in which the suspension is only a supplementary operation.

He believed that in suspension we have a method of permanently relieving a large percentage of patients suffering from retroflexio uteri. Dystocia in future pregnancies [illegible] the [illegible] of ligature [illegible]. Hernia of the abdominal wall, adhesions, and [illegible] of general [illegible] are [illegible] and should not occur.

Intraabdominal Shortening of the Round Ligaments Per Vaginam for the Cure of Retrodisplacements of the Uterus.—In a paper with this title Dr. J. Riddle Goffe of New York said that gynecologists are uniformly agreed that the ligament which serves the most important function in supporting the uterus is the sling of tissue reaching from the promontory of the sacrum, known as the uterosacral ligaments, to the posterior wall of the cervix, plus the uterovesical ligament reaching from the anterior wall of the uterus to the symphysis pubis. This is reinforced by the cellular tissue and ligamentous structure in the base of the broad ligament. So long as the uterosacral ligaments retain their proper tone and length, swinging the cervix high in the hollow of the sacrum, retroversion of the uterus is impossible. It is for some malign influence affecting the uterosacral ligaments, therefore, that we must look for the cause of retrodisplacements of the uterus, and it is consequently to the repair or the recovery of function in the uterosacral ligaments that we must look for restoration to normal condition. Unless the indirect result of any operation for maintaining the uterus in its normal position is to enable the uterosacral ligaments to involute and recover their tone and sustaining power, that operation becomes a failure. That this can be secured by direct operative procedure upon the uterosacral ligaments themselves he is convinced from experience.

The next most favorable tissue to utilize for this purpose is the round ligament. This is attested by the results secured by many operators upon the round ligament in various ways. Alexander and others have demonstrated that the round ligaments, when shortened at the external abdominal ring, are efficient in maintaining the uterus in its normal position when applied to cases of retrodisplacement uncomplicated by inflammatory process. Olshausen has shown that the round ligaments when caught up near to the uterus and attached to the edges of the abdominal incision are efficient and satisfactory in restoring the uterus to its normal position. Wylie, Mann, and many of their followers have had complete satisfaction in simply doubling the round ligaments upon themselves and stitching them in that position through an abdominal incision. Duhrssen, Wertheim, and Vineberg have presented most conclusive statistics bearing upon the entire efficiency of shortening the round ligaments through the vaginal incision by catching them up near the horns of the uterus and stitching them to the anterior vaginal wall. The same German operators, Duhrssen, Wertheim, etc., and in this country Byford and the essayist attest to the equal efficiency of operating through the anterior vaginal fornix, and doubling the ligaments on themselves in accordance with the Wylie-Mann suggestion. He had not found a method which had given him such universal satisfaction as this. He reported 130 cases that he had subjected to this procedure during the past sixteen years and he knew of only three failures, and these were due to having departed from the typical procedure in which a modification was attempted. Among these cases ten are known to have become pregnant and eight have gone to full term, the pregnancies resulting most comfortably and satisfactorily, the uterus retaining its proper position thereafter. Of the miscarriages one was in a hospital [illegible] and in the other the cause could not be learned.

The superiority of this method over [illegible] ligament [illegible] upon the general question of the value of the vaginal route of attack over the abdominal route, and the comparatively wider field of application as compared with the Alexander operation.

Among his cases he finds [illegible] of congenital retroversion in young, unmarried women, whose ages ranged from fourteen to thirty-seven years. In these cases, although the vagina was small and the hymen intact in all of them, he was able to perform the operation and effect a complete cure in all.

Operations on the Uterosacral Ligaments in the Treatment of Retroversion of the Uterus.—Dr. J. Wesley Bovée of Washington, D. C., recounted briefly the surgical treatment of the uterosacral ligaments in retroversion of the uterus. The first operation for shortening the uterosacral ligaments through the vagina was done by him on June 28, 1897, and since that time he has had seven other cases, all successful. By the abdominal route he began shortening these ligaments, February 21, 1900, and since then on three other occasions the operation has been done.

The method of shortening these ligaments through the vagina, as he has planned and practised it, is to place the patient in the extreme lithotomy or Simon's position, and with a self-retaining perineal retractor in place, the posterior lip of the cervix is grasped with a vulsellum forceps and drawn forward. An anteroposterior incision is made through all the structures of the posterior vaginal fornix except the peritoneum, and extending approximately from the cervix to the rectum. By careful dissection the ligaments are brought plainly into view. Then grasping one of them with a forceps midway between the extreme points to be united and lessening the traction on the cervix at the same time, the fold of the ligament is brought down into the vagina; then a curved needle armed with kangaroo tendon is passed through the ligament at the extreme points noted and another through the loop thus formed and through the posterior portion of the cervix below the insertion of the ligament. When the other ligament has been treated in a similar manner the two deep sutures are tied, and then the others. The wound is now spread well open and the two ends of it approximated by a continuous kangaroo tendon suture. When the wound is closed it appears to have been originally a transverse one. Sometimes he has modified it by separation of the anterior vaginal wall from the uterus and converting the wound into a longitudinal one or by transplanting the wall higher on to the uterus. When adhesions have been thought to exist in the retrouterine space, the culdesac has been entered and the adhesions separated. In all instances he has shortened the round ligaments through the anterior fornix.

By the abdominal route the plan he has followed is to use the Trendelenburg position, remove the intestine and omentum from the pelvis, and by the use of a special long retractor hold the uterus and appendages well forward and upward. Then, tracing the uterosacral ligaments with the fingers, to properly locate them, a longitudinal incision is made through the peritoneum near the inner margin of one of these. The ligament is then partially dissected loose and is treated much as the vaginal route. The peritoneum is closed by a purse-string suture, or by the plan of closing the vaginal wound

The other side is treated similarly and the abdomen closed. He has, in a few instances, shortened the round ligaments at the same sitting.

The results of the various operations for shortening the uterosacral ligaments were given. The author's own work in shortening the uterosacral ligaments consists of eight vaginal and four abdominal operations.

As to the advantages of the operation, the extraperitoneal shortening of these ligaments, with the adjoining portion of the vaginal wall, is practically devoid of danger, and is frequently indicated. The abdominal route is less frequently required. Yet, with the abdomen opened, perhaps for some other purpose, shortening of these ligaments would be very little extra risk to the patient, or an extra tax upon the part of the surgeon. It does not have the same conditions incident to ventrosuspension and ventrofixation which are considered by some as real dangerous, and it is supporting nature's supports to this important reproductive organ.

A Further Contribution to the Study and Practical Significance of Lactation Atrophy of the Uterus.—Dr. Hiram N. Vineberg of New York read this paper. Although the writer six years ago drew the attention of the profession to lactation atrophy, the subject has not yet received the consideration that it deserves, as is evidenced by the literature and the recent textbooks on obstetrics. It is a physiological process accompanying lactation, with or without amenorrhea, the atrophy or superinvolution being temporary only, the return to the normal size being in some cases dependent upon the cessation of lactation. In others, again, the regeneration of the uterine tissue occurs while lactation is still going on. It is not to be confounded with what is commonly known in this country as hyperinvolution, which is usually permanent in its character, although in some rare cases it terminates in this form. While the author has seen during his ten years' service at the dispensary over five hundred cases of lactation atrophy, he has not met with more than twenty cases of permanent hyperinvolution.

When the atrophy is slight and is manifest only by a thinning of the uterine walls, it is known as "eccentric atrophy," when it is more marked, as is evidenced by a marked diminution in the size of the uterus, the term "concentric atrophy" is employed.

The cervix usually participates in the atrophic process, but the ovaries, as a rule, do not. The hyperinvolution or atrophy is fully established between the eighth and twelfth week, and persists for a variable period in different nursing women, its persistence usually being dependent upon the continuance of lactation. Anæmia does not play an important rôle in the causation of the condition, as has been stated by some writers, notably Engström. The author had the blood examined in a series of cases, and he found that the degree of atrophy bore no relation to the diminished number of red blood cells and to the lowered percentage of hæmoglobin. Cases with the smallest uteri had the highest number of red blood cells and the highest percentage of hæmoglobin.

Hyperinvolution may occur independently of lactation, as shown by Hansen and P. Müller. Most writers hitherto have concerned themselves chiefly in showing that lactation atrophy is not an injurious condition, and that it seldom leads to permanent atrophy. But the writer drew attention to its decidedly beneficial effects upon the uterus in bringing about a normal hyperinvolution. Therefore, women who nurse their babies are rarely the victims of subinvolution, with its usual sequel, chronic metritis, one of the most unsatisfactory and rebellious conditions to treat. When, as is usually the case among the better classes, the mother is unable or disinclined to nurse her baby, it is the duty of the attending obstetrician to keep the parturient under observation, and treatment, until nearly the same degree of hyperinvolution is established as obtains in lactation. This period will seldom be less than eight weeks and will frequently extend to three months. Unfortunately, the importance of this desideratum is not very generally recognized. The accoucheur rarely considers it necessary to examine the parturient after the second or third week.

In concluding, the writer drew attention to a peculiar circumstance, that in the class of women from whom he draws his material in dispensary practice uterine cancer is exceedingly rare. From the fifteen hundred to sixteen hundred new patients he sees yearly, not more than one or two are the victims of cancer of the uterus. One would expect almost the opposite, if improper attendance during the puerperium and lacerations of the cervix play any rôle in the causation of that dread disease. He asked the question whether the circumstance that these women are shielded, in a great measure, against the occurrence of chronic metritis, renders them less susceptible to the development of uterine cancer.

President's Address.—The Relation of the Gynecologist, Obstetrician and General Surgeon.—Dr. Seth C. Gordon of Portland, Me., selected this for his Presidential address.

He said it was the custom of late years to say that gynecology had passed its usefulness, and had become merged into general surgery, and that there no longer existed the necessity for attempting to prolong the life of this hopelessly doomed department of medicine. With this proposition he took issue, and maintained that, until modern obstetrics approached more nearly to the ideal standard, there would be a large field for the gynecologist proper. Scientific gynecology had its birth in America, and was founded by Marion Sims. No gynecological surgery prior to his day had made any impression on surgical practice that had endured until the present time. That which the keen, brilliant genius of a Sims made possible, the intelligent, patient, practical commonsense of an Emmet made probable to every afflicted one of womankind. The field was wide and from all parts of the country came the sufferers from childbed injuries, many of which were due to the faulty obstetric work of that day. Among the causes were long-delayed use of the forceps; careless and needless use of forceps; a disregard of the accidents occurring; and a total lack of aseptic precautions during the progress of labor. From the first came vesicovaginal fistula; while from the second came lacerations of the uterus and perineum, many of which could have been remedied had the accoucheur regarded them at all, and treated them according to the best known surgical principles. The great fault lay in entirely ignoring such accidents.

There are many faults yet to be overcome in the practice of obstetrics before the millenium shall dawn for the gynecologist. While public institutions are doing good work in eliminating germ diseases, and bringing the mortality almost to the vanishing point, much missionary work needs to be done among professional men in private practice.

The criticisms he offered were: (1) The too early use of the forceps. When the pendulum began to swing from rarely using the forceps, it went to the opposite extreme, using them far too often. A very large majority of cases will, if left alone, terminate naturally; (2) Cases of accidents occurring in labor are not properly repaired at the time.

The fashion of late seems to be to prohibit antiseptic douches after labor. While it may be necessary in normal labors, with no accidents, lacerations should be kept surgically clean, and it can be done only by frequent irrigation and germicides. Surgical cleanliness on the part of the accoucheur and patient from the beginning of labor until convalescence, insure safety to one and duty well performed on the part of the other.

As an additional safeguard against laceration of the perineum, he believes the timely use of anæsthetics in-

[illegible] In [illegible] the part of the [illegible] of the [illegible] [illegible] [illegible] The [illegible] [illegible] [illegible] and [illegible] the patient.

[illegible] hemorrhage is less due to the use of [illegible] and to the prolonging of the anæsthetic. [illegible] careful [illegible] [illegible] of the uterine [illegible] during the [illegible] of the child and [illegible] until firm contraction is [illegible] [illegible] every case. His own experience fully [illegible] in making the operation then a direct [illegible] of adherence to this [illegible] [illegible] prevent post-partum hemorrhage.

Modern methods of Cæsarean section had given such good results in diminishing mortality that the indications of [illegible] had practically ceased, and the [illegible] which [illegible] such abundant gynecological material had correspondingly decreased. This great progress was practically due to anæsthesia, asepsis, and improved technique, and for this credit should be given to gynecologists who had perfected the operative details of abdominal section, made possible by the discovery of anæsthetics and cleanly surgery.

Laceration of the cervix, especially of long-standing, was not always an indication for trachelorrhaphy, destruction or extreme atrophy of tissue of the cervix being a decided contraindication to the operation. Thousands of women suffered much more after trachelorrhaphy than before. The cervical canal was closed too much, drainage prevented, and often infection developed in the uterus and tubes, and the last condition was much worse than the first. Emmet never taught such gynecology as that. He did not even teach that all lacerations of the cervix required an operation. On the contrary, he believed that many of them did not require any interference simply because they were not producing any morbid symptoms. The tendency had been too much in the direction contrary to Emmet's teaching, with the result that gynecology had been brought into disrepute. Many symptoms attributed to laceration of the cervix had been found to be due to disease of the other pelvic organs.

The plastic operation of perineorrhaphy, so often done by the general practitioner, to say nothing of the general surgeon, was far too often apologetic, when compared with the work of Emmet, Thomas, Marcy, and others throughout the country.

The best work for malignant disease of the pelvic organs had been done by gynecologists. Probably no man could show better results in the way of relief and even cure of cancer of the uterus than Dr. John Byrne. Whether hysterectomy in any stage of the disease was to be the ideal method was by no means well settled. He believed that a more careful examination and more close observation of women under the care of physicians would detect malignant disease in its earlier stages, at a period when hysterectomy might be the ideal operation.

Much yet remained to be done with plastic operations about the vagina, not only in relation to prolapsed uteri, but for vesicocele, and diseases of the urethra, especially that of caruncle. Incisions into the posterior culdesac for acute inflammatory attacks, whether attended with pus or not, well deserve the attention of the gynecologist. While this was one of the early gynecological operations for pelvic abscess, without reference to ulterior results, it was now well-known that thousands of women could be saved from long and painful illnesses and subsequent hysterectomy by the timely common-sense application of the surgical principle of removing the products of inflammation as soon as formed.

Treatment of Placenta Prævia—Cæsarean Section Not Justifiable.—Dr. Robert A. Murray of New York, in a contribution on this subject, referred to a paper read last year before the American Association of Obstetricians and Gynecologists, by Dr. Zinke of Cincinnati, on [illegible] it [illegible] In Zinke's paper a strong plea was made for the treatment of placenta prævia by Cæsarean section. Dr. Murray [illegible] and [illegible] the [illegible] by proper treatment [illegible] the performance of the operation [illegible] In fact, only a very small [illegible] of cases of placenta prævia would be [illegible] by Cæsarean section.

Dr. J. Whitridge Williams of Baltimore questioned the propriety of Cæsarean section for placenta prævia, and said the operation had been too frequently [illegible] as to the [illegible] [illegible] If the society did not take a decided position in regard to Cæsarean section in cases of placenta prævia he feared that the operation might be employed as frequently and indiscriminately as was symphysiotomy. In his opinion there was a small field for Cæsarean section in placenta prævia.

Dr. Edwin B. Cragin of New York said the conditions which would justify Cæsarean section in placenta prævia were so numerous that they were seldom found present, and among them were a good condition of the child, good surroundings for the patient, and a cervix so rigid that there would be great difficulty in dilating it and resorting to version. These three conditions were rarely met with in cases of placenta prævia. A fourth condition was central implantation of the placenta.

Dr. Philander A. Harris of Paterson, N. J., said that when the statistics were analyzed as to the mortality of the mother and child, it would be found that the more rapid, prompt, and effective the delivery, the less the mortality, and the better the general results. If the case could be seen when the first hemorrhage occurred, it would be a favorable time for Cæsarean section, but which he would not advise, but try to effect delivery by other methods.

Dr. Charles Jewett of Brooklyn said the results under modern obstetric methods of treatment of placenta prævia were good, whereas the mortality from Cæsarean section was much larger than had been claimed by its advocates.

Dr. E. P. Davis of Philadelphia said that the Cæsarean section in placenta prævia must have a very limited application at present. Among the poorer classes of women with placenta prævia the mortality among children must be great, with a considerable mortality among mothers. However, he was not willing to universally condemn Cæsarean section in placenta prævia, for his personal experience with this operation had led him to look upon it as successful under favorable circumstances.

Dr. A. Palmer Dudley of New York said the general practitioner should be educated in regard to placenta prævia. He should study his cases more carefully, and make a diagnosis of placenta prævia sufficiently early to refer them to specialists, thus saving the lives of many children and mothers which otherwise would undoubtedly be sacrificed. He thought there was not much use in performing Cæsarean section after a profuse hemorrhage had taken place. The danger of this operation, when properly and promptly performed, was almost *nil*.

Dr. Egbert H. Grandin of New York said he would treat a case of placenta prævia after the same manner that he would a case of carcinoma or sarcoma of the uterus. He would go at it with hammer and tongs, just as soon as he was sure of his diagnosis, and no matter what the period of gestation, he would empty the uterus. His experience had been fairly extensive, and his results from this hammer and tongs policy had been very favorable as regards saving the mothers. He had never had a mother die, although the mortality was considerable as far as the children were concerned. But usually these children were nearly dead when seen.

Two Conditions Simulating Ectopic Gestation.—Dr.

Edward P. Davis of Philadelphia read a paper with this title, in which he reported the following cases:

Case I.—A multipara had pelvic pain at intervals, with disordered menstruation for several months. She had been exposed to cold and wet during the menstrual period. Her husband, a physician, had made intrauterine applications and had introduced a sound. After nine months of such illness the patient developed an hæmatocele, filling the cavity of the pelvis. Abdominal section was declined and vaginal section permitted. Considerable clotted blood was removed by vaginal incision, the cavity washed out and packed with iodoform gauze. This gauze was gradually removed in ten days after the operation. After the removal of the gauze the patient gradually developed symptoms of septic infection, ending fatally. Abdominal section was declined, and autopsy was not permitted. The examination of blood clot removed after section gave no evidence of ectopic gestation. This case resembles others recently reported by Kober (*Centralblatt für Gynakologie*, No. 39, 1901), and also observed by others, in which pelvic hæmatocele has accompanied diseased conditions of the pelvic viscera other than tubal gestation.

Case II.—An emaciated, anæmic woman, aged twenty, had previously had an abortion between three and four months. Bleeding was very profuse and was controlled with great difficulty. Several months after she became pregnant, and had attacks of intermittent pain, with hemorrhage from the vagina and a rapid feeble pulse. Upon examination the pelvis was filled with a soft, boggy tumor, completely occupying the posterior culdesac. The body of the uterus could not be distinctly outlined, but was enlarged. The patient's condition indicated hemorrhage, and abdominal section was performed. A retroverted pregnant womb was found, filling the pelvic cavity, the tubes and ovaries being normal. The womb was replaced and pregnancy proceeded for some time, and the patient left the hospital. She subsequently returned and aborted at six months. The uterus was found lined with clotted blood at the time of abortion

Segond, Routier, and Varnier have recently reported to the Obstetrical Society of Paris similar cases. In obscure cases of hemorrhage in which a diagnosis is not evident he thinks abdominal section is safer than continued uncertainty. Conditions simulating ectopic gestation usually require prompt interference and surgical treatment.

Dr. Charles P. Noble of Philadelphia presented a clinical report on ureteral surgery.

Dr. Edward Reynolds of Boston discussed the principles underlying the repair of cystocele, and an operation founded thereon.

Dr. E. E. Montgomery of Philadelphia spoke of the relative advantages of complete and partial hysterectomy.

A New Method of Anterior and Posterior Colporrhaphy.—Dr. I. S. Stone of Washington, D. C., read a paper on this subject.

Anterior operation.—The vaginal wall is incised in the median line, and after clamping the sides of this incision, the bladder is pushed away, upward and backward, until its entire base is separated from the vaginal wall and from the anterior surface of the uterus, if desired. He extends this separation as far out laterally as possible, for the whole pelvic roof shares in the prolapse. He proceeds now to lift the bladder with fingers or gauze packing, or with a sound inside the organ as far upward as possible to assure the extent of liberation. The excessively long flaps which presented over the base of the bladder as a cystocele (the distended anterior vaginal wall) are now excised, and the wound brought together edge to edge, taking care to entirely obliterate the cystocele and to leave the new anterior vaginal wall straight across. The method of applying the sutures is important, for he invariably sutures the flaps near the center of the wound to the anterior surface of the uterus with silkworm gut, silk or chromicized catgut. This is done for the double purpose of holding the bladder high above the former attachment on the uterus, and to hold the uterus forward if it has been retroverted. The bladder is held away and the deep sutures passed through the uterine wall between the attachments of the round ligaments. The wound is then entirely closed with catgut sutures. It will be noticed that he has applied the Mackenrodt method of vaginal fixation to his operation, but it was primarily to hold the bladder higher upon the uterus rather than to cure the displacement. In very large cystoceles the vaginal wall is greatly lenthened and can be shortened by removing a V-shaped section from each side of the incision in front of the cervix. The longitudinal wound in the median line will then join one made transversely across the vagina in front of the cervix.

As a test of the efficiency of the method, two patients with procidentia were selected, each with large cystoceles, who consented to operation in two stages. Both women were nearly sixty years of age. One had prolapse of twenty years' standing; the other, a stout, fleshy woman, had not suffered so long, and her disability was largely due to increase in weight. The vaginal relaxation of the thin woman was extensive and complete. The fat woman had not sustained as severe laceration as the other, but was hardly as good a subject, owing to the size of her abdomen. The anterior operation alone was done on these women, and while the uterus was not entirely retained within the vagina as a result of the work done, the cystocele was cured. One of these women had the final operation upon the posterior wall before she left the hospital; the other returned nearly a year later, was treated in the same manner, and now both are well.

Posterior Secondary Operation.—Injury to the posterior vaginal wall and perineum differs greatly in its extent, and in the direction of the tear. The rent may be longitudinal or transverse, and in any event needs to be fully exposed below the vaginal mucous membrane, which in the past has borne the brunt of surgical attack, while the fascia, the objective point, is hiding with the much discussed and rarely seen levator ani muscle, and is only influenced by sundry excursions of needle and suture, which, after all, only hold a denuded or scarified mucous membrane together while union progresses. The crest of the rectocele is grasped with the left hand, making a transverse fold, which is divided with the scissors down to the rectum. Clamps are applied to the edges of the incision, and the rectum pushed away on both sides with a gauze sponge until it is quite free of all connection with the vaginal wall. The incision in the vaginal wall is extended above and below until we are satisfied that we can secure sufficient narrowing of the vagina to answer the purpose in view. The sutures are placed with greater facility when the rectum is separated freely on each side, and one need not have any fear of not obtaining good union after the operation. After he has completed the liberation of the rectum, and has clamped such hemorrhoidal vessels as give trouble, he closes the wound in the following manner: With tissue forceps he catches up two points, one on either side, which he wishes to unite in front of the rectum. These points are usually about one and one-half inches below the edge of each flap, but the size of the rectocele will necessitate a test in each case, as directed, so that good approximation of the fascia over the rectum may be secured, which will not exert undue traction upon the sutures. The fascia is firmly and thoroughly united along the entire length of the wound. In some instances he has used a double tier of sutures, which gives excellent support to the floor of the vagina, and makes a firm obstruction to the exit of a procident uterus. After the buried sutures are placed to overcome the very hard tissue on each side, and close the ruptured recesses with interrupted catgut down to and rather below the former site of the crypt of the rectocele. Emmet's or Hegar's method may then be adopted for the final stage of the operation, according to the predilections of the operator. The operation in some respects resembles that of Hegar, the chief difference being in the method of exposing the fascia.

A Consideration of Ovarian Fibromata, Based on a Study of Two Recent Cases and Eighty-two Collected from the Literature.—Dr. Reuben Peterson, of Ann Arbor, Mich., read a paper on this subject. The writer's first case was a woman aged 41, who noticed a growth in the lower left abdomen five years previous to her entrance to the hospital. The growth had increased until it reached the height of the left side. There was little or no pain—in fact, very little discomfort from the growth. Operation performed December 19, 1901, disclosed a large tumor of the left ovary, weighing seven and one-quarter pounds. The tumor was lobulated, the smaller lobe being pedunculated. The larger tumor showed partial calcification. Microscopic examination showed the tumor to be a fibroma. The patient made an uneventful recovery.

In the second case the patient was sixty years of age, and entered the hospital for distention of the abdomen from ascitic fluid of four years' standing. During this time she had been tapped sixty-five times. At the operation, April 25, 1902, there was found an irregular, hard, fibromatous tumor of the left ovary, weighing three pounds. There were a few adhesions present, and the other ovary was the size of a hen's egg from a surface papilloma. There were seven hundred cubic centimeters of clear ascitic fluid removed at this time. The microscopic examination showed an ovarian fibroma of the left side. Except for an attack of gallstone colic, proved by the passage of four gallstones, the patient made an uneventful recovery.

While fibroma is one of the rarest forms of ovarian new growths, it is by no means such a rarity as was formerly supposed, as has been conclusively shown by Doran, Briggs and Coe. Briggs reported eight cases from his own practice, and the writer's two cases were met with within four months.

From a consideration of the eighty-four tabulated cases, it was found that the age is mentioned in all but one. As compared with fibromyomatous uterine tumors, it was found that these growths were about twice as often discovered from forty to fifty as are ovarian fibromata, the percentage of the former being fifty-one, as compared with 28 per cent. in the latter.

The conclusions to be drawn from the writer's cases and those collected were that (1) Fibromata of the ovary occur earlier and in relatively greater numbers during early sexual life than do fibrous growths of the uterus; (2) While relatively the largest number of ovarian fibromata are to be found during or just after the menopause, a considerable percentage of cases occur proportionately later in life than do uterine fibromyomata.

Of the sixty-six cases in which the social state was mentioned twenty-two were single and forty-four were married, showing the disease to be twice as common in married as in single women. The statistics do not bear out the statement of Dartigue, that pregnancy prior to the development of the tumor is rather a rare occurrence, since 85 per cent. of the thirty-three women where fecundity is recorded had had one child or more. The twenty-eight women averaged four children each. The cases were carefully reviewed regarding the effect of the ovarian fibromata upon the menstrual function. In only two cases is it definitely stated that the tumors gave rise to irregularity in the menstrual period. In 40 per cent. the statement is made that the patients were regular. Six patients, or 12 per cent., are recorded as having had painful periods, but there is no evidence to show that the pain was produced by the ovarian growths.

The author thinks that neither menorrhagia nor metrorrhagia is a very constant accompaniment of fibromata of the ovary. It is more apt to occur where both ovaries are affected by the disease. The growth of an ovarian fibroma may exist for many years before the tumor reaches large proportions or gives rise to marked symptoms. In other cases the growth is more rapid, reaching considerable proportions and giving rise to noticeable symptoms in a comparatively short time, say a few months. Pain is present to a greater or less degree in nearly one-half the cases of ovarian fibromata. Freedom from pain means, as a rule, the absence of adhesions of the growth to the surrounding organs. Pain is more frequently met with in tumors of moderate size. [illegible] is a complication in about 17.6 per cent. of the cases.

The growths were described as fibromata in sixty-three out of the eighty-four cases, or in 75 per cent.; [illegible] of these were fibromata, twelve were fibromata and fibroma with calcified infiltration, fibroma with mucoid degeneration, and fibroid with hyaline and myxomatous changes, one each; [illegible], or 27 per cent., were found to be fibrosarcoma; two were called myofibroma, and there was one each ascribed to the [illegible] and to the myofibroma with hyaline degeneration.

Closure of Suppurating Abdominal Wounds Following Laparotomies.—Dr. Philander A. Harris, of Paterson, N. J., read a paper on this subject. When abscess forms in the abdominal incision the skin is reopened in the line of incision to the upper and lower limits of the mural abscess. The wound is then treated as an open one until the flow of pus becomes greatly reduced in quantity. All the granulations are then removed with a sharp curette until the muscle, fascia, fat and other tissues are distinctly recognizable. The separated edges of the deep fascia are then drawn together by a series of silkworm gut sutures, which interlock each other at the opposition line of the fascia. Each one of these sutures is introduced through the skin about one inch away from the incision and each one is brought out either just above or below the point of its introduction. If the first suture both enters and emerges from the right of the median line, the next one is introduced and emerges at a point to the left of the incision and is so introduced as to interlock the first and preceding suture. The third suture is introduced and brought out from the same side as the first suture and interlocks the second one. The fourth suture is introduced from the same side as the second suture and interlocks the third or preceding one. This singular suture has for its chief object the coaptation of the deep fascia, and when properly introduced and tied it is claimed that the fat and opposing edges of the skin fall in apposition, adhere and heal without additional sutures. Most of the few cases thus treated heal promptly and generally do so without suppuration. A not unimportant part of the technique of operation is the thorough and repeated washing with a solution of bichloride of mercury, always followed with a normal salt solution irrigation. The stitches are all removed on the twelfth and fourteenth day.

Fifteen photographs which were exhibited, illustrate much of Dr. Harris' work in this relation. A not uninteresting part of the photographic illustration was the appearance of the wound after the sutures were introduced and tied, as they converted the area of the open and large wound into an elongated mound, at whose base on either side there appears a row of knots, while at the summit of the mound the opposing edges of skin simply lie in apposition, awaiting adherence and healing.

Dr. Harris is of the opinion that the stronger solutions of carbolic acid, or possibly other disinfectants, might serve as good if not better, purpose than the solution of bichloride of mercury which he has employed for this work.

Officers.—The following officers were elected for the ensuing year: *President*, Dr. Joseph E. Janvrin, New York; *Vice-Presidents*, Dr. Edward W. Jenks, Detroit, Mich., and Dr. A. Palmer Dudley, New York; *Secretary*, Dr. J. Riddle Goffe, New York; *Treasurer*, Dr. J. Montgomery Baldy, Philadelphia.

Washington, D. C., was selected as the place for holding the next annual meeting, in conjunction with the Triennial Congress of Physicians and Surgeons, the first week in May, 1903.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, Held May 15, 1902.

ROBERT F. WEIR, M.D., PRESIDENT.

Stomach Vertigo.—Dr. CHARLES SUMNER FISCHER read this paper. He said that stomach vertigo was of that character in which everything whirls around the patient like a revolving wheel. Nausea usually followed the attack, and was associated with pain in the stomach radiating to the back, and usually with constipation. There was no loss of consciousness and no misconception of the hallucinations. The attack usually occurred on an empty stomach, but might take place after an ordinary meal. At times the gastric symptoms were very indefinite. Attempts had been made to associate gastric vertigo with well-defined pathological conditions in the stomach. A review of the literature showed a wide difference of opinion regarding the state of the stomach in these cases of vertigo, and also as to its frequency. There was reason for believing that gastric vertigo might result reflexly from either cerebral congestion or anæmia. Since the work of Bouchard in 1884, on intoxications, gastric vertigo had been included in the long list of affections supposed to be due to autointoxications. It had never been proved that there was any direct relation between gastric vertigo and abnormalities of the stomach secretions. In the early stages of chronic gastritis it was quite possible that hyperchlorhydria might exist, but in the later stages it was not present and the vertigo then would be associated with diminished acidity. In all cases of chronic gastric disease in which the nervous system was diseased, one should be slow to make the diagnosis of gastric vertigo. The most common form of chronic gastric disease met with in this country was the nervous atonic variety, and it was with this form that stomach vertigo was most often associated. It was possible that in this variety the general nervous system had suffered in nutrition to such an extent as to make it particularly vulnerable to stimuli from distant organs. Vomiting was a common accompaniment of vertigo, whatever its origin, and hence, the mere presence of nausea and vomiting was not sufficient to establish the diagnosis of gastric vertigo. To attempt to make such a diagnosis from the character of the vertigo was futile. The cases of gastric vertigo could be conveniently studied in three groups, viz.: (1) Those cases of vertigo accompanied by nausea, palpitation and intense fear, following indiscretions in diet; (2) Severe attacks occurring in the course of chronic disease of the stomach without any indiscretion in diet; and (3) Mild and fleeting attacks occurring in the course of chronic gastric diseases and general neurotic conditions. He was inclined to think that true gastric vertigo was rare and belonged only to the second of these groups.

Tympanic Vertigo.—Dr. WILLIAM P. BRANDEGEE defined tympanic vertigo as that form characterized by changes or pathological conditions in the middle ear. These conditions of the middle ear comprised all those tubal changes caused by difference in atmospheric pressure; those changes in the tympanum due to inflammatory products, either fluid or solid; those changes due to connective tissue products, and those changes the result of residual products. The vertigo arising from venous engorgement of the walls of the Eustachian tube or from hypersecretion of the lining membrane, was usually mild in type, but where there were hypertrophic changes the vertigo was often exceedingly severe. Frequent inflation, preferably by the catheter, was indicated in the congestive cases. The use of the nasal douche in congestive conditions should be prohibited as a prophylactic measure. In the acute catarrhal and purulent cases early incision of the drum membrane might be indicated. After the subsidence of the acute symptoms there should be given a course of middle-ear inflation in order to restore the hearing and break up any adhesions that may exist. In the more severe inflammatory cases it might be necessary to remove the ossicles or even do a Stacke operation. The patency of the Eustachian tube should be restored, and, in the speaker's opinion, this was best accomplished by electrolysis.

The Neurological Diagnosis of Vertigo.—Dr. PEARCE BAILEY read this paper. He said that iodide of potassium was often given in large doses by neurologists, and that it sometimes was responsible for attacks of intense vertigo. In migraine vertigo was often one of the symptoms of the fully-fledged attack. In neurasthenia and hysteria vertigo was usually subjective. It was less frequently complained of in the latter, and did not appear to be so constantly present. The more important cases of vertigo coming under the notice of the neurologist were those due to organic disease of the brain. In these the centers in the medullar and cerebellum were involved, directly, as by sclerosis, tumors, hemorrhage, thrombosis, abscess and trauma, and indirectly, by changes in blood pressure. In the pons and medulla tumor was the most common cause. Vertigo due to changes in blood pressure was observed chiefly in connection with that form of epilepsy known as petit mal, and in general paresis. Cerebral endarteritis was also a fertile cause of vertigo due to brain disease; indeed, vertigo was often one of the prominent symptoms of advanced arteriosclerosis. As a symptom of apoplexy, vertigo was important, and often occurred for weeks before the apoplectic attack. In the cerebral manifestations of syphilis vertigo was a symptom of the highest importance.

Dr. WILBUR B. MARPLE said that the form of vertigo most commonly seen by the ophthalmologist was that dependent upon diplopia following paresis or paralysis of some of the ocular muscles. The less conspicuous to the observer the ocular anomaly the more apt was the patient to suffer from vertigo. If closing one eye does not cause a disappearance of the vertigo, then the other eye should be closed, when it would at once disappear. The treatment was that appropriate to the underlying cause, and the patient should be made to wear an exclusion glass. In many individuals, especially if neurasthenic, very gratifying results often followed the correction of very slight errors of refraction. For the time being any muscular anomaly should be ignored, but if the correction of the refractive error brought no relief the lack of muscular balance must receive attention.

Dr. MAX EINHORN was of the opinion that vertigo was found in almost every known disease of the stomach, and in many disorders, also of the intestine. Vertigo should be attributed to the stomach if there was a gastric catarrh or a manifest abnormality of the stomach secretion. According to his experience, this form of vertigo was not so often due to autointoxication as to some reflex disturbance.

Dr. J. F. McKERNON said that vertigo was sometimes caused by foreign bodies and growths in the external auditory canal, as well as by masses of impacted cerumen. He thought about one-half of the cases of vertigo coming to the notice of the aurist were due to residual inflammation or its results. Labyrinthian vertigo might be traumatic, syphilitic, alcoholic and endarteritic. He had seen vertigo in a number of cases of mumps not only in the acute stage had [illegible] after the inflammatory process had subsided.

Dr. E. B. Dench said that the best type of labyrinthine vertigo was found in syphilis of the labyrinth, either of the hereditary or acquired form, and here, too, brilliant results were often secured. The aural symptoms might develop long after the primary lesion, and yet by the administration of [illegible] the physiological [illegible] relief was usually afforded. The same treatment was applicable to the vertigo occurring in connection with otitis media, with the [illegible] of the [illegible]. In cases of [illegible] vertigo there was elevation of the lower tone limit and interference with the upper tone limit and no [illegible] of bone conduction. On the other hand, if the vertigo were due to disease of the labyrinth, the bone conduction would be practically nil, the lower tone limit unaffected, and the upper limit changed.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, New York City, for the week ending May 31, 1902:

	Cases.	Deaths.
Measles	545	12
Diphtheria and croup	264	36
Scarlet fever	323	26
Smallpox	63	2
Varicella	61	
Tuberculosis	212	138
Typhoid fever	26	5
Cerebrospinal meningitis		3

New Street Cleaning Process.—Commissioner Woodbury of the Street Cleaning Department intends to make this city the cleanest one in the world. To this end he is willing to test every contrivance or apparatus brought to his attention which can be utilized to bring about this desirable end. A few weeks ago he tried a pick-up sweeper with no material results. He is now testing a new cleaning apparatus, which consists of a tank made of steel holding 618 gallons of water, which is charged with compressed air used for forcing the water through a fine slit in a pipe, which juts down from the end of the tank at the rear of the wagon, from which it is thrown in a fine sheet of water. This spray of water is thrown with such force as to loosen and lift the dirt and refuse to one side of the street into the gutter. In traversing the street it covers a space of about eight feet, and begins the work in the center.

It takes about 15,000 gallons of water to clean a mile of asphalt pavement twenty-six feet wide. After the system is installed and has been in use a few days, going over the street once a day will, it is asserted, keep it in a perfectly clean condition, but to start with it is necessary to go over it two or three times in order to soften and remove the dirt which has dried to the pavement when in a slimy, sticky condition. One machine cleaned Fifth avenue from Twenty-third street to Washington Square in less than three hours' time, beginning work at about 5 A.M. One machine, with a clear street, under ordinary conditions, it is asserted, will clean 60,000 square yards in a day. Unlike street sweepers, it can do its quickest and most effective work on a wet day, as then the dirt of the street is thoroughly loosened from the pavement and it becomes a comparatively easy matter for the spray of water to push the dirt into the gutter. Under such conditions, it is declared, more than 100,000 square yards could be cleaned in a day. For a stone street it takes about 10 per cent. more water to clean the same amount of pavement and 10 per cent. more time.—*New York Tribune.*

A Large Filtering Plant.—A recent inspection by Mayor Ashbridge of Philadelphia of the great filtering plant of that city at Torresdale was most satisfactory. The work has progressed so fast that the plant will be finished in a little over two years, its cost together with the conduits for carrying the filtered water to the city being about $8,000,000. The tract of land on which the filter-beds are being built covers 416 acres. The preliminary beds are on the bank of the river, and adjoining them will be erected the low-service pumping station. Next will come the fifty-five slow-filter beds, connected with a clear-water basin, which connects with the big conduit, which carries the water over a mile to the pumping station, which supplies three-quarters of the city with water. The manner of working the plant will be as follows: With the low-pressure pumps the water will be lifted out of the Delaware River to the two rapid filters, each having a daily capacity of 60,000,000 gallons. By gravity the roughly filtered water will go to the fifty-five slow filter beds, the combined capacity of which will be 200,000,000 gallons a day. After the slow filtration the water will run to the clear water basin, and then by gravity through the big conduit 125 feet underground to the pumping station. The slow filtration beds, covering about fifty acres, will be arranged in groups of eleven, and between the groups will be courts and thoroughfares. The top soil is being saved, and when the beds have been cemented over they will be covered with the soil and sodded, and will present the appearance of well-kept lawns. They have an elevation of 214 feet above the level of the sea. At the experimental station excellent water is being supplied by both the slow and rapid processes. The cost of rough filtration will be about fifty cents a million gallons, and of the slow filtration about $2.50 a million gallons.—*New York Evening Post.*

Health Reports.—The following cases of smallpox, yellow fever, cholera, and plague have been reported to the Surgeon-General, U. S. Marine Hospital Service, during the week ended May 31, 1902:

THE PRESIDENT'S ADDRESS.*

BY JOHN ALLAN WYETH, M.D., LL.D.,
NEW YORK.

SINCE the session held at St. Paul a year ago, a former president of this Association, paying the last great debt to nature, has passed

"To where beyond these voices there is peace."

Full of years and beyond the limit allotted by the Psalmist, Professor Edward Mott Moore, born in Rahway, N. J., July 15, 1814, died in Rochester, N. Y., March 3, 1902. He was one of the founders of the New York State Medical Association, a consistent and loyal friend of our national body and of an organized medical profession. Although his achievements in science were of a high order, his life was not circumscribed within the narrow limits of professional work. He was not only a skilful surgeon, bold and original, but more than this, he was a citizen of the highest type. The welfare of his neighbors, of his adopted city, state and the Nation were his May his noble example be emulated, for it is just as much our duty to be true to the obligations of citizenship as to our profession.

Before dealing with the more urgent matters of this meeting, your attention is called to the Fourteenth International Congress of Medicine, which is to be held at Madrid from April 23 to 30, 1903.

As your presiding officer I had the honor to receive an appointment from the Secretary of State as a delegate to represent this association at the Congress, and was requested by him to appoint five additional delegates from this body. In conforming to this request the following gentlemen have accepted commissions, and have received certificates from the State Department to the Congress: Dr. Nicholas Senn of Illinois; Dr. Maurice H. Richardson of Massachusetts; Dr. George Crile of Ohio; Dr. Richard Douglas of Tennessee, and Dr. Edward B. Dench of New York.

It should be the duty and pride of the separate state associations to send at least one delegate to this important meeting, and in doing this to correspond with Dr. Angel Fernandez-Caro, Secretary-General, Fourteenth International Congress of Medicine, Madrid, Spain.

This session marks an era in the history of the American Medical Association, for we meet under changed conditions, and in this our trial year, while we are adjusting ourselves to the new order, we confidentlly ask and expect to receive not only the consideration and forbearance, but the generous help which should be accorded to this experiment in government by which we earnestly hope to avoid the embarrassments and failures that under the old régime characterized the meetings of a body so large and unwieldy as the general session.

These changes involve not only the government of the association proper, but also a changed relationship of the state association to the national body, as well as the relationship of the county to the state organization. Under the old organization our business was transacted by delegates from state, district, and local affiliated societies in the proportion of one delegate for each ten members, while now, only affiliated state organizations have the right to send delegates, and these are only entitled to one delegate for each five hundred active members, or a fraction of this number These form the House of Delegates, which is further reenforced by two members from each of the scientific sections of the association, and one each from the Army, the Navy, and the Marine Hospital service. Under the old régime the state association bore the same relationship to the national body as did the city, county, and district organizations. Now, only the state association is represented, and they create the legislative body of the American Medical Association. In other words, the House of Delegates is a federation of all the state associations.

The reorganization at St. Paul, having taken away from the county organization its right to send delegates, also deprived the city and district branches and other minor associations of the same privilege, requiring membership in the county society when such exists as a prerequisite to membership in the state and the American Medical Association. This ruling dropped, at least temporarily, from the rolls of the association a considerable number of physicians who had long been on the roster from state or local bodies which, by the laws then existing, were in affiliation with the National Association. While this action may have seemed unnecessary and unjust to these members (among whom were many of the most loyal and faithful supporters of the national body) for the common good, they should yield to the opinion of the majority, since calm reflection must convince any reasonable mind that one of the wisest steps the association ever took was when it made the county medical organizations the basis of membership in the national body. There will hereafter be excluded from membership that, fortunately, small, but none the less existing group of unworthy members of our profession who, on account of the clumsy rules which formerly prevailed, obtained a place on the roster of the American Medical Association.

To the date of the reorganization in June, 1901, the roster of this Association was so inaccurate and unsatisfactory that the secretary and president-elect undertook the difficult task of obtaining a correct list of members. While one might infer that each organized state and territorial association could, from its records, furnish, at short notice, the names of all eligible to membership in the American Medical Association, in only a very small proportion of these subordinate bodies was a reliable list available. It then became necessary to direct a circular letter, state by state, to every name on the roster then existing, asking for the necessary information. Since, for final confirmation, these names must be referred back to the subordinate organizations in which membership is claimed, it will be seen that some time must elapse before the completion of a perfectly reliable list. The lack of business-like methods with which our profession is charged is in a measure sustained by this admission, and it emphasizes the necessity of a thorough reorganization of all the societies in affiliation with the national body, upon practically a uniform plan.

---

*Delivered at the Fifty-third Annual Session of the American Medical Association at Saratoga Springs, June 10–13, 1902.

Scarcely second in importance to a uniform scheme of reorganization is that of a uniform standard of requirements for the practice of medicine in the various states. It is of vital interest to the welfare of the profession that the question of reciprocity or interstate comity should be settled so that without any sacrifice of the very highest requirements, a physician in practice in one State, having gone before a competent board, upon change of residence might be permitted to practice without being subjected to a second state examination in the place of his adoption. The House of Delegates will, without doubt, act upon this matter at this session.

Referring to the subdivisions of the scientific work of the association, Article V of the constitution empowers the House of Delegates "to authorize new sections which may from time to time be organized, as the necessity for their existence arises." With increasing membership and the consequent larger attendance, it may be imperative in the future to create new sections; but this should be done only after careful consideration, and not until it is demonstrated that the material of high scientific value offered to the twelve sections now existing is more than can be utilized in the time allotted for the meetings.

The by-laws require every member to register in one of the sections, and it would be well to limit each reader to a single paper before the section chosen. The association should insist that the officers of sections exercise a most rigid scrutiny of the papers referred to them. If we are to achieve our high purpose, if we wish to attract to our organization the great bulk of the better element of the medical profession, we must present through our sections papers which demonstrate not only the high scientific attainment of the author but the undoubted value of the material presented. We are judged by our works, and if at our meetings and in the publication of our papers in *The Journal*, which carries them to all parts of the earth, any unworthy material finds a place, it can but reflect discredit upon the association.

Article VI of the new constitution says: "The House of Delegates shall have authority to provide for and to create such branch organizations as may be deemed essential to the promotion of the welfare of the medical profession."

For the present I would not advise the establishment of these subdivisions, but ultimately it may be found necessary to divide the States and Territories according to population and geographical position into district branches where meetings may be held at the convenience of the States represented, and without interference with the annual session of the National Association.

Let us hope that the various Tri-State societies and the sectional organizations, such as the Southern Surgical and Gynecological Association, and the equally successful Mississippi Valley Medical Association, and others of like character, attracted by the high and unselfish aims of this organization, may appreciate the vital necessity of a united profession and vote themselves into district branches of the American Medical Association. Truly in such a union there would be strength so potent, and influence so far reaching that we could safeguard without doubt the material interests of the profession, elevate still higher the standard of medical education, secure the enactment and enforcement of just and rigid medical laws, enlighten and direct public opinion in regard to the broad problems of State medicine, and demonstrate to the world the practical accomplishment of our science.

Article VII of the new constitution, which deals with "Sessions and Meetings," refers the place and time for holding each annual session to the House of Delegates. They are also, under Article IX, empowered to appropriate funds for defraying the expenses of the annual meeting, as well as for enabling the standing committees to fulfill their respective duties.

I would recommend to the consideration of the association the propriety of selecting in each of the geographical subdivisions of the United States, in which the sessions are successively held, some suitable location which has been found to be well adapted to the work of the organization, and to which we could return when the meeting is again to be held in that section of the country. As a scientific body, intent upon fostering the growth and diffusion of medical knowledge, it is of vital importance to avoid in the selection of our place of meeting everything that could detract from the closest attention to the scientific program. The smaller cities with ample hotel accommodations and halls conveniently located, have always yielded a larger attendance before the sections, and consequently a greater benefit to our members than the cities of larger size with their multitude of distractions. Moreover, it seems scarcely in accord with the dignity of this great body to require through its committee of arrangements that the physicians of the State and place selected for the convention should be held responsible for the expenses of that meeting. Every suggestion of commercialism should be avoided, and this prosperous organization should assume the entire responsibility and management of these annual sessions.

One of the most important duties imposed upon the House of Delegates is the selection of those who conduct its business affairs. In the past, the association has shown a keen discernment in securing for its trustees and standing committees men, not only of executive ability, but held in high esteem as representatives of a profession which, according to the code of ethics, "should be temperate in all things, and which requires greater purity of character and a higher standard of moral excellence than any other calling."

You will in the regular order of business hear the reports of your five standing committees, and I am called upon to speak of but one, viz.: The Committee on Medical Legislation which the by-laws adopted in June of 1901 directs to be appointed by the president, and to consist of one delegate from each State. In accordance with this requirement I mailed to the president of each State and Territorial organization in affiliation with the American Medical Association a letter asking him to nominate one member for this committee. To all replies to this letter the name of the delegate was sent to the chairman of the National Committee on Medical Legislation, Dr. H. L. E. Johnson, Washington, D. C. It will be remembered that at the session in St. Paul in 1901 the association ruled that the National Committee on Medical Legislation, consisting of Dr. H. L. E. Johnson, Washington City; Dr. William H. Welch, Baltimore, and Dr. W. L. Rodman, Philadelphia, should be continued until the meeting in June, 1903, and should have the same power to act in the interest of the association that they had previously enjoyed All the legislative affairs of the association I have referred to this committee at Washington, and have authorized them to call the full Committee on Medical Legislation for consultation, advice or aid whenever their services might be required.

In his message to Congress, December, 1901, the President recommended the establishment of a Department of Commerce and Industries. In its passage through the Senate the name was changed to that of Commerce and Labor. Before the national legislature at the same time was a bill known as the Perkins-Hepburn bill to increase the efficiency and to change the name of the United States Marine-Hospital service to that of the United States Health Service, transferring this from the Treasury to the new department

The American Medical Association has on several occasions expressed its desire for the establishment of a Department of Public Health, either as a separate department of the Government, or as one of the important bureaus of a department Probably on account of a lack of thorough organization and coöperation, it has not been able to obtain this important recognition for the medical profession. In view of these repeated failures it would seem advantageous to the scheme of establishing ultimately a Department of Public Health that the Perkins bill should become a law, because the United States Marine-Hospital Service could then with more propriety be removed from the new Department of Commerce and Labor into a separate and independent department. This department should be in charge of a medical officer to direct our foreign and insular quarantine, interstate quarantine, the medical supervision of epidemics, and, in fact, all matters pertaining to the general health of any group of States, or of the entire country.

The work of this office and bureau can only be carried out with success by the earnest coöperation of the health officers of the various localities and States, and of the advisory board for the hygienic laboratory provided for in the Perkins-Hepburn bill, for the national and local authorities acting in harmony would be better able to prevent the importation of disease, and to stamp out epidemics which may occur despite the greatest vigilance, and this with the minimum disturbance of the resident public and of the commercial interests of more remote sections.

As the representative organization of the medical profession of the United States, it is our duty to coöperate with the medical corps of the army in the effort to procure legislation which will not only uphold the rights and dignity of the medical officers in the public service, but will give better protection to the health and lives of our troops.

The status of the Medical Department of the United States Army is fairly stated in a circular issued by the medical officers stationed in the Philippines, in which they claim that the present condition of affairs "is regarded as a menace to the efficiency of the medical department, as it is felt to be unfair and unjust." In no other staff department is promotion so slow as in the medical department. It is graded for rank, promotion and pay below every other staff department of the army, and, with the exception of second lieutenant, is graded below the line. A medical officer, under the provisions of the present law, to obtain a colonelcy must pass through three times as many files as an officer of the Quartermaster's, Subsistence or Pay Departments; through more than twice as many files as an officer of the Engineers' or Ordnance Departments, and more than one and one-half times as many as an officer of the signal corps. Officers of the line having obtained the rank of major, have to pass through but four files to obtain the rank of colonel, while the medical officers have to pass through nine files. All these facts are fully appreciated by the younger physicians of our country and by the volunteer and contract medical officers, hundreds of whom are now serving with troops and are declining to become candidates for a position offering such an unpromising career and so little in the line of promotion and emolument.

The Secretary of War has been officially informed by the Surgeon-General that the number of available medical officers is being rapidly diminished, and he anticipates he will soon be unable to supply the demand for medical officers to replace those constantly returning from the Philippines, unless the prohibition placed by the Secretary of War upon the appointment of additional contract surgeons is removed. He says: "The service would no doubt be more attractive to well-educated physicians if the prospects for promotion were better, and I respectfully recommend that Congress be asked at the present session to add to the medical corps of the army, two colonels, six lieutenant-colonels and twenty-five majors. This would give thirty-three additional vacancies and would furnish an incentive to volunteer medical officers and contract surgeons now in service to seek admission to the regular army. I would also recommend that the age limit for volunteer surgeons and contract surgeons who have rendered satisfactory service for two years or more be raised to thirty-six years."

No one who has carefully studied the subject can but conclude that under the statues now in force many lives have been sacrificed and much suffering has resulted from lack of thorough coöperation between the officer in command and his chief surgeon, and without doubt it would be to the interest of the service if medical officers were always consulted with regard to the location of camps and military posts for the purpose of getting expert opinion upon sanitary questions.

In order to impress upon commanding officers the importance of military hygiene, and the greater necessity for this coöperation with the medical corps of the army, the Surgeon-General has insisted that there should be established at the Military Academy at West Point a course of instruction in military hygiene.

It is the duty of this association to lend its best efforts to the Surgeon-General, a former president of the American Medical Association, and one not only in a position to suggest the legislation which would best serve the interests of the army, but one whom we know to be zealous of the interests, rights, and dignity of the medical officers of the War Department.

The committee to whom were entrusted the question of vivisection has been diligent, and it would seem successful, it its efforts to prevent unwise and injurious restrictions upon this important method of research.

The wide dissemination of the contagion of smallpox in the United States within the last few years demands the most earnest attention of the medical profession Such ignorance or indifference to the immunizing power of vaccination is a matter of surprise in an advanced state of civilization and, while laws for compulsory vaccination would without doubt be to the best interests of the whole people, it seems so contrary to the spirit of our in-strictures as to be impossible as well as impracticable. It falls upon us as physicians to labor unceasingly to impress upon the communities in which we reside the necessity and safety of this restraining process.

We will be wise if from time to time we make a critical analysis of our past, realize exactly what we are doing, and upon this base such conduct as will assure to our successors a more satisfactory condition of our profession and a higher achievement of this association. Being human we are too apt to shut our eyes to unpleasant truths, to exaggerate the value and the importance of our own performances and to think that what we have been taught to believe, or what we wish to believe, is right and unchangeable. Let us ask ourselves plainly: Is the medical profession of the United States what it should be? Has it won the influential position to which it should aspire? Has it gained the power to secure just and proper legislation? Has it lived up to its obligations, and has the American Medical Association, which claims to represent one hundred and twenty thousand regular practitioners of medicine in the United States, fulfilled its mission? How many of us after due reflection can consistently answer these questions other than by saying plainly and regretfully —No. And wherein lies our weakness? To say we are part of a young and scarcely organized country, that our profession is widely dispersed over vast regions so remote from each other that contact and coöperation are difficult will not entirely satisfy the fairly critical mind. Such excuses might have been sufficient at an earlier date, but not now. It will not be sufficient to say that, despite these and other embarrassments, we of the United States have given to mankind the unequaled boon of ether anæsthesia, that, through the achievements of members of our profession and of this association medical and surgical science has been greatly enriched, that great specialties recognized the world over have been developed, that operations bold and original have been established beyond controversy, and that by reason of these various contributions to the science and art of surgery and of medicine millions of lives have already been saved, together with the merciful mitigation of suffering which all this implies. While a repetition of this may flatter our vanity, it will not wholly satisfy us when in honest purpose we realize how great are our shortcomings.

It is a fact painful to acknowledge that of the three so-called learned professions, the ministry, law and medicine, ours is accorded the inferior position, and we who, day in and out, in every home of the land, are close to the personal friendship of our patients, respected and loved as individuals, are incapable of wielding by organization and discipline the powerful influence of a united profession aiming at a high and honorable purpose. And what have been the results of this house divided against itself? Witness the snail-like progress which marked the various steps in securing our laws for elevating the standard of requirements in medical education and for medical practice. Witness the opposition to our efforts in securing better sanitary regulations, and in the struggle to protect the public from the horde of uneducated or misguided persons who under the guise of Christian Science, Osteopathy, and other schisms, insist upon being permitted to take charge of and treat human beings suffering from disease without submitting themselves to the State examination legally required of us.

There are, in my opinion, two principal causes of this evident weakness of the profession. First: The insufficient methods of medical education which have prevailed for the greater part of the first century of our national existence. Second: The lack of organization.

The Code of this association says: "Those admitted into our ranks should found their expectations of practice upon the extent of their qualifications." We stand committed as the champion of higher medical education and the elevation of the standard of requirements applicable not only to the entrance examination but to a rigid examination before the degree is received, as well as by the State before permission to practice is granted. To this rigid examination this association, by its rules of conduct, demands another important essential. The highest order of learning, the greatest amount of skill may not make one an honor to our calling, for "there is no profession from the members of which greater purity of character and a higher standard of moral excellence are required than the medical, and to attain such eminence is a duty which every physician owes alike to his patients and his profession."

The American Medical Association is the sponsor for organized medicine in the United States, and failure to accomplish this end implies the failure of this association. We must not fail, nor will we, unless we falter in carrying out the plan of reorganization in the liberal and progressive spirit which characterized the session of 1901. It is our plain duty to endeavor to bring about the adoption by the various constituent bodies of a practically uniform constitution and by-laws for each county, and for each State, modified only as the local conditions may require, and all governed by the same rules of conduct. These rules, as at present given in the Code of Ethics, adopted many years ago by this association, should be also a subject of serious consideration at this time, for we cannot claim consistency or be logical in argument until there is but one code for the national association and for all of the State organizations represented in the national body. This, as you well know, does not now prevail. Some years ago there lived and labored among us for the good of mankind and the honor of the profession a man whose genius was of the highest order, and whose fame carried the name of American surgery throughout the civilized world. He was one of those fearless pioneers in science who found his place ever on the frontier clearing the way for those who were to follow. In 1876, at a meeting of the American Medical Association, in Philadelphia, Dr. J. Marion Sims, in his presidential address, referring to the Code of Ethics, says: "The time will come when your organic laws, like the Constitution of our country, will require modifications and amendments to suit a higher intelligence, a broader education and a greater destiny." In my opinion, the time has come when we cannot absolve ourselves from the responsibility of doing away with the inconsistencies for which we may now be properly criticised.

Such have been the changes in the statutes of a majority of the States since the Code was adopted by the respected founders of this association that we find it insisting upon conduct on the part of our members which is contrary to the laws of the States in which they reside. For instance, one section forbids a member of the regular profession to act upon a board of examiners which has to pass upon the legal qualifications of persons not graduates of regular medical colleges, while in thirty-eight of the States represented here the civil statutes require these boards, which are composed in great part of members of the association, to examine, pass upon and sign certificates or licenses to practice of Homeopaths, Eclectics, and other subdivisions of medical practice. In six of the States, including the District of Columbia, the law requires three separate examining boards. In Mississippi, North Carolina and South Carolina the examining boards are entirely composed of regular physicians, and in one of these States (Mississippi), while none but regulars are allowed on the board, the law explicitly says: "Distinction shall not be made between applicants because of the different systems or schools of practice that may be chosen." In almost all the States and Territories regular physicians are compelled by the laws of the State in which they reside to disobey the injunctions of this section of the Code of Ethics.

A modification of this and other sections of the Code must be a part of the liberal plan of reorganization which we have essayed.

In conclusion, I ask this association to stand for more than the healing art. To labor for the alleviation of suffering and for the restoration of health is a noble avocation, but to teach our fellows how to avoid disaster is a prouder privilege and a higher duty. We should be teachers of men. How better can we protect the public from disease in all its various forms and insidious processes than by perfecting in every county and in every community an organization which shall be ever watchful and insistent upon obedience to the laws relating to the public health?

STATE MEDICINE, PAST, PRESENT AND FUTURE.*

By J. M. EMMERT, M.D.,
ATLANTIC, IA.

STATE medicine had its origin with Moses, the great legislator. The bloodthirsty Egyptians of the dark ages, who in superstitious ignorance destroyed the lives of those among them who differed from their belief or creed, left nothing which the human race could follow for the preservation of health and life. Thirty odd centuries ago, the great lawgiver, Moses, laid down sanitary rules, regulations and exercises which are followed at the present day by all civilized and semi-civilized nations.

The Sanitary Code of Moses.—Some 1,300 years before the Christian era, the code contained in the Mosaic Exodus laid down restrictions on every possible act that mankind may perform to impair or impede existence. Such as they are, it is hardly possible to improve upon them at this enlightened day. Moses instructed his people that those sanitary commands were inspired by a Supreme Being; that the only health officer in existence was the Almighty, who could watch over their trespasses against the law. No matter where they might be, or what they might do, the Supreme Overseer would bring them to justice for the violation of the code of health.

It was handed down to the Israelites in an oral way for about one thousand years, when it became corrupt and neglected, like other laws of long standing when there is no one to enforce them.

About six centuries before the Christian era, the great Sanhedrin was formed; it consisted of seventy-two men, who compiled the oral law to a written law, adding to it, besides the moral, every possible sanitary regulation that may benefit human health and life. This tribunal enacted laws to improve every possible means of securing healthy food, clothing and shelter, and established minor judiciary courts in every possible community, and gave these courts the right to bring before themselves anyone who violated the sanitary measures. The laws of the Sanhedrin were enforced and well kept for hundreds of years, during the time that Judea could establish and enforce its own laws, but when it fell under the sovereignty of the Romans, they were unable to enforce the laws with Roman influence; consequently, they were kept only by the pious Jews.

The Justinian Law.—The infidels could not be compelled to keep the commands under the Roman law. Hence the pious Jews of the sixth century appealed to the Roman Emperor Justinian, under whose reign a code was compiled by sixteen eminent jurists, establishing laws for all Roman States, and quoting decisions mostly from the Jewish Talmud, including many moral and sanitary measures, which is now termed the Justinian Law. Besides adopting many of the Talmudic laws, which did not differ from the Mosaic, they added many practical and sanitary regulations. It is to the Justinian Law that our present civilization is indebted for the abolishment of polygamy. It is to the laws of Justinian that we are indebted for the prohibition of the marriage consanguinity. The combination of the Mosaic, Talmudic and Justinian laws forms a fair code for the preservation of human life. The Bible itself is one of the very best textbooks on hygiene that has ever been written. He who strictly follows its teachings will be a perfect sanitarian. "We must learn," says a distinguished writer, "to regard physical as well as moral sins as greatly displeasing in the sight of God."

Features of the Mosaic Law.—Jewish hygiene and diet are well known for their regulation to healthy food, for the Jews are restricted to certain fish of the waters and certain beasts of the field. It is from the Mosaic Law that we have learned to legislate against unwholesome food, especially of animal food. Every one of us knows with what care the Jews kill their cattle and their fowl, and with what care the autopsies are made on the animals before they are declared fit for use.

The sanitary laws of Moses provided for the segregation of lepers and the fumigation and destruction of infected clothing. These had great influence on Christian nations when contagion was recognized in epidemics, and probably most of them were, from the standpoint of to-day, either directly or indirectly infectious, and a grand advance in preservative methods became possible. All European nations enforced laws for limiting the spread of leprosy, and these, which have been handed down from ancient times, had merely to be modified in their application in order to exercise a controlling influence on the spread of fulminant febrile diseases.

Pestilence and Superstition.—Before and after the beginning of the Christian era, plagues, pestilences and famines were classed together as of divine origin. The Greeks and Romans, from the evidences of their authors, resorted to forms and ceremonies to avert epidemics. Statutes were erected to Æsculapius and Apollo; Sibylline books were consulted, nails were driven into the walls of the Temple of Jupiter Capitolinus, and the Lectisterne ceremonies were among the remedies applied to epidemics before the time of Christ. Later, festivals, mournings, and founding of religious structures were resorted to in order to appease the divine anger, to which the epidemics were attributed. For hundreds of years, thousands and thousands of human lives were sacrificed from various pestilential and infectious epidemics of which we now seldom hear. The so-called sweating plague of the latter part of the fifteenth and the first part of the sixteenth centuries has not been heard of since 1551. Black death and epidemics of cholera with its ravages as late as 1848 and 1849, and the pest of the tropical countries, yellow fever, to say nothing about the various other zymotic epidemics and infectious diseases such as typhus, diphtheria, scarlatina, etc., have become a rarity among civilized nations. Livy tells us that during epidemics the Roman citizens shut themselves up in their houses and paid attention to nothing except how to preserve themselves from the pestilence. Boccaccio refers in his tales to the attempts made by Florence to preserve her citizens from the plague which overspread Europe in 1346 by denying access to all sick persons.

---

*Oration on State medicine, delivered before the fifty-third annual meeting of the American Medical Association at Saratoga Springs, N. Y., June 10–13, 1902.

The First Quarantine.—The first arrangement for the isolation of the sick and quarantine establishment against infectious diseases reach back to the tenth century. Charles IV, in 1347, made a statute for German states including certain measures for the isolation of the sick and quarantine establishment against certain diseases.

In 1348 a "Board of Supervision," a sort of council of hygiene, which in the end served as a model for all Italy, was first established in Venice. At Majorca, in 1374, a committee of officials presided over by a physician, Lucien Colomines, was appointed with extensive powers, to whom the local magistrates at the outbreak of the plagues were directed to report.

This committee was also allowed a hospital, and it was directed that no ship should discharge passengers nor unload freight without their knowledge, nor should any port sales be held without preceding notice to the sanitary council. Suspected ships were required to keep quarantine for forty days, hence the name quarantine.

In 1348, the year of the extension of the black death, it was noted by many observers and especially recorded by Gabriel de Mussis, who fled from the Crimea to Plaisance in France, that ships and passengers from the East conveyed the disease. That same year Venice, then the center of maritime commerce, appointed three provveditors of health to take measures for the prevention of the plague. Count Barnabo, in 1374, issued a decree at Reggio, in Italy, that any person attacked by the disease should instantly leave the city, fortress or castle for tents in the open country, until recovered or dead; that persons attending the sick should not consort with others until after the lapse of ten days, that the priests should examine and notify the infected sick to the inquisitors, and that all goods and property of persons infected, or who conveyed infection, should be confiscated to the use of the church, and none but those appointed should, under penalty of death and confiscation, attend upon the plague-stricken.

In 1382 Chalin de Vinario demonstrated that contagion was the cause of the spread of the plague. The following year Count Barnabo prohibited entrance of persons from infected localities under penalty of death; and his successor, Viscount John, in 1399, ordered the city gates to be guarded against admission of strangers from infected places, infected houses to be fumigated and thoroughly ventilated for a long period, clothes and bedding to be washed and dried in the open air, bed-spreads to be exposed for days in the open air, and all refuse matter and rubbish to be burnt.

In 1400 the Berlin butchers were compelled under the law to take the following oath: "I will sell no sucking sow, no consumptive or one-eyed cattle, and no cattle purchased from poor people out of the hospitals."

Extension of Quarantine.—During the fifteenth century severe measures were employed in times of pestilence. Boards of health were frequently convoked and strict health ordinances issued. "It is forbidden to attend foreign markets and fairs. Whosoever, however, has attended fairs must undergo quarantine; the guards of the gates were strengthened, suspected persons were not admitted and strangers must bring evidence that they had not sojourned in places affected by the pestilence. 'Blotterhauser' were built, the attendants were forcibly pressed into service as nurses, the sick were shut up in their houses, suitable directions as to mode of life, even as to purification of the washings of the body and bed, on interment, etc., were published. The council sought to suppress the use of secret remedies, sorcery and necromancy, amulets were interdicted and burned."

The first quarantine port was established at Marseilles in 1526, and during this century the system of quarantine extended to most of the maritime cities of the Mediterranean, and many inland cities adopted similar precautions.

In 1546 the work on contagions and contagious diseases, by Fracastor of Venice, declaring contagion to be exhaled by the body, infecting those at hand directly through the air, and those at a distance through the medium of fomites, induced greater measures of exclusion. By degrees, the practice of quarantine extended over the whole civilized world, and the penalty measures were increased in severity. Torture and death awaited alike those who remained in the city, when ordered out, and those who entered when forbidden access. In the sixteenth century not only were ships with their passengers and cargo detained in prolonged quarantine, but towns also were surrounded by sanitary cordons and completely blockaded for long periods, and even individual houses in the towns were closed against exit and entrance. Food and necessaries were obtained with difficulty and by the most circuitous methods of exchange, whilst politics, commerce and social intercourse stagnated.

Quarantine in the United States.—The first quarantine act adopted in the United States under the colonial system was passed by the General Assembly of Pennsylvania in 1700, and was entitled, "An act to prevent sick vessels coming into this Government." It imposed a penalty of one hundred pounds on any infected vessel which landed in the province. Other quarantine acts of greater or less severity were adopted by Massachusetts in 1701, Virginia in 1722, Delaware in 1726, North Carolina in 1755, New York in 1758, Maryland in 1760, etc. The first general quarantine act adopted by Congress was passed February 23, 1799, and was designed to be supplementary to the various State acts. It was entitled, "An act respecting quarantine and health laws."

During the eighteenth century maritime quarantine and lazarets extended, especially on the Mediterranean coast, and increased in importance when inland pandemics subsided in severity. The quarantine services under boards of health, with their stations, lazarets, detentions, disinfections, numerous attendants and complicated ordinances, became large organizations. Europe was less frequently invaded by plague against which maritime quarantine was almost entirely directed; therefore the lazarets were neglected, and the administration became lax. At the end of the century John Howard made strong protests and, in the beginning of the nineteenth century, cholera and yellow fever made their advent. This revived the interest in the prevention of pandemics, and shook the confidence placed in quarantine, as it was practiced at that time.

International Sanitary Conferences.—The severe measures designed for plague in the seventeenth and eighteenth centuries were adopted for cholera and yellow fever in the nineteenth century, and they were embodied with modifications in a lengthy convention, accompanied by an elaborate international sanitary code. At the International Sanitary Conference held in Paris in 1851, and represented by twelve European powers. This convention did much to spread ideas of municipal hygiene in place of useless quarantines. Inspection of dwellings and destruction of sources of infection were strongly advocated. In the United States various yellow fever and other epidemics called attention to the subject. In the city of New York, in 1866, a metropolitan health board was established, organized on the same lines as the English sanitary acts. Later, in 1869, Massachusetts established a State board, and other States and cities rapidly followed. Ten years later, in 1879, Congress created a national board of health, and to-day municipal hygiene is receiving a great deal of attention.

Municipal hygiene in Europe has been carried to a much forther degree than in the United States. At the International Sanitary Conference, held in Vienna in 1874, much modification with regard to quarantine was commenced. Inland quarantine was rejected as inadmissible. The Conference of Constantinople recommended the establishment of a strict quarantine in the Red sea, for the purpose of preventing importation of cholera into Europe, and was met with approval. This was regarded as the strategic point in the line of defense, and therefore tended to weaken reliance upon quarantine in Western ports, and medical inspection was considered as a possible substitute in conjunction with local sanitary measures. Sir John Simon, Medical Officer of the Privy Council, in his memorandum, expressed the views of the local government board upon the prevention of cholera, which greatly influenced the opinions of the delegates. The precautions recommended in detail, the various means applicable for the removal of filth, and the protection of water supplies, combined with careful disinfection of the discharges of any person who might be attacked.

In 1881 an international sanitary conference was held in Washington, and was attended by the representatives of twenty-seven States, including all the governments of Europe, except Switzerland. They discussed measures desirable to prevent the spread of yellow fever and cholera. No uniform agreement was arrived at on all points, but some of the recommendations were adopted by many of the foreign governments. After the invasion of Egypt by cholera in 1883, and of Europe in 1884, an international sanitary conference was held in Rome in 1885. The interested powers were represented by their embassadors or other diplomats, assisted by technical medical delegates. They traced the course of shipping from its point of departure from ports and cities where cholera is endemic, for instance, Bombay, Calcutta, etc., and followed it through the Red Sea, the Suez Canal, the Mediterranean, to the open ocean. Later they considered the indications for inland precautions, and recommended the security of correct statements of sanitary conditions by the presence on big vessels of government medical officers independent of shipping companies, the disinfection on board, by means of steam chambers, of all soiled or dirty articles, the enforcement of strict precautions against the spread of cholera by the pilgrims to and from Mecca. Respecting the detention of ships, the powers represented expressed opinions that were arranged in the three following groups: Turkey, Spain, Mexico, Brazil, etc., favored the continuance of long quarantines. France, Germany, Austria, Hungary, Switzerland, Russia, Sweden, Norway, Italy and Portugal yielded to the data of modern science; whilst desiring short periods of quarantine they favored such detention as deemed necessary upon travelers and commerce; England and India advocated free passage without detention. Regarding quarantine, however, the opinions of Continental nations have been undergoing modification. At the International Congress of Hygiene, at Paris, during the exhibition of 1889, Dr. Proust, Inspector-General of the sanitary service of France, concluded a report on sanitation in seaport towns with the following propositions: "That it is the duty of governments and municipalities to render ports healthy; that sanitary works for seaport towns are more necessary than for other towns; that it is only after such works that any notable reduction in zymotic diseases and general death rates takes place, and that it is only when ports present a refractory soil for the penetration upon shipping can be suppressed." In spite of the dubious signification of the last resolution, there was ample indication that quarantine was slowly but surely being whittled down to small proportions.

Most of the microphytic diseases are found to prevail more or less in all parts of the civilized world. Certain are more prevalent in temperate zones; others are peculiar to the tropics, and are exotic in relation to this country. There are many diseases indigenous to certain tropical areas, but which are not naturalized in this country, such as Oriental plague, Asiatic cholera, yellow fever, dengue, yaws, elephantiasis, endemic hæmaturia, and chyluria. Oriental sore, and Madura foot. Besides these, some diseases, such as malaria and dysentery, appear in a more severe form in tropical than in temperate zones. On the contrary, scarlatina, erysipelas, whooping cough, cerebrospinal fever, and what is known as cholera nostras, are more common in temperate zones.

Epidemics in the United States.—According to the late Dr. Toner, the most important epidemics which prevailed in the United States during the eighteenth century were as follows:

Smallpox: In Boston in 1701, 1702, 1721, 1730, 1752, 1764, 1776, and 1792; in New York in 1721, 1731, and 1752; in Philadelphia in 1730–32, 1736, and 1756; in Charleson, S. C., in 1700, 1717, 1732, 1738, and 1760.

Yellow Fever: In Boston in 1796 and 1798; in New York in 1702, 1732, 1741, 1743, 1791, 1795, 1798, and 1799; in Philadelphia in 1741, 1762, 1793, 1797–99; in Charleston, S. C., in 1700, 1703, 1728, 1732, 1739, 1745, 1748, 1749, 1753, 1755, 1758, 1792, 1794, 1795, 1796, 1797, 1799; in New Orleans in 1769, 1791, 1793-95, 1797, 1799, 1800.

Scarlatina: (According to J. Lewis Smith, first imported into the United States in 1735.) In Boston in 1702, 1735, 1795; in New York in 1792–94.

Measles: In Massachusetts in 1713, 1739, 1769, 1773; in New York in 1788 and 1795; in Philadelphia in 1771, 1773, 1778, 1796; in Charleston, S. C., in 1747, 1759, 1772, 1775.

Angina (Diphtheria): In Kingston, N. H., in 1733–35; in Boston in 1735, 1769; in New England in 1737, 1742, 1787, etc.

Growth of the Hospital.—The first hospital, or rather pest-house, was established in 1403 by the proveditors of Venice, on an island near that city, but only those actually attacked by plague were at first admitted. Later several other maritime cities in the Mediterranean founded similar institutions.

Hospitals especially for the insane were established first at Fez in Africa, then at Seville in 1409, then at Palma 1410, Saragossa 1425, Toledo 1483, and [illegible] in [illegible].

These hospitals may be regarded, however, rather as houses of correction or penitentiaries. In Lubeck these houses of detention were called "Tollkisten" (insane boxes), and were under the charge of the police rather than as institutions for the care and treatment of the inmates.

In 1460 in Frankfort on the Main there existed nine so-called insane asylums, each nine feet long, broad and high, one of which contained a crazy woman, another a priest, a third a crazy apothecary. Of medical treatment there was not the least thought. The insane wallowed about in chains and without clothing in these horrible dens, covered with filth and their own excrement, as long as they were able to endure. Toward the close of the Middle Ages, the treatment of the insane became a little better, especially in free cities, where compassionate citizens assumed their care instead of police jailers. This practice first started in Lubeck, in 1478. Proper houses for the guardianship of the insane were also called into existence, gradually, by the example, donations, etc., of others.

Medicolegal Beginnings.—We find that in the twelfth century there were State physicians and surgeons as advisers in forensic medicine. In 1249 Hugo of Lucca received from the burgomaster a commission to draw up a legal opinion, and as early as 1209 Pope Innocent III recommended the appointment of such physicians in canon law. In France and in the kingdom of Jerusalem sworn surgeons were employed by cities and courts, as medical experts, as early as the thirteenth century. Physicians and surgeons were employed as public witnesses, each in his own department.

In the fourteenth century city physicians were required to take an oath to conform to certain instructions, the transgression of which involved a penalty. In this same century there existed at Strassburg the so-called "Libenzuchter," who exercised supervision over the moral and sanitary relations of the inhabitants. Strassburg had its first city physician in 1328.

Growth of Pharmacology.—Arabians first started apothecaries in Europe, in Italy, about 1135, and in Spain in 1140, at Cordova and Toledo. Frederick II, in 1224, enacted a pharmaceutic ordinance differentiating the druggist from the apothecary. The former was dealer in spices, essential oils and raw drugs, the latter compounded medicines.

In the thirteenth century there existed in France an "instruction" for apothecaries. The latter formed a guild, about fifth in rank. In the early part of the fourteenth century they were raised to the second rank, their "masters" being allowed to wear long black gowns and wide sleeves and velvet facings, like the judges. They, with the merchants, preserved the standard weights of Paris. The physicians were their overseers. Many compound remedies were prepared by them in the presence of medical magistrates, chief among these compounds being theriaca, which was thus prepared even in the eighteenth century, so as to escape adulteration.

Germany boasts of its first pharmacy in 1233. London was the seat of the first apothecary shop in 1345. In France, in 1330, a law was enacted for the inspection of apothecary shop.

The first law under State Medicine regulating apothecaries was enacted at Strassburg in 1400, and at Stuttgart in 1486, which ordinance is still in force, and reads as follows: "That drugs must always be well selected and not decayed, that nothing except what is prescribed shall be put into a medicine, especially nothing dangerous by way of substitution, that the apothecary shall be responsible for his clerks, and shall not give any poisonous drug or any abortive, that the price list of the apothecary shall be correct, that in doubtful cases he shall apply to the physician," etc.

Since the time of Frederick, inspection of pharmacies has been added as a regular public function of physicians. It was practised at Ulm in 1426, in Frankfort on the Main in 1461 and in Berlin in 1499.

The First Pure Food Laws.—Spain in 1483 passed an ordinance relating to adulteration of food and delicacies, the sale of poisons, and love potions, infection of the air by putrefying animal matters, etc. Strict imperial ordinances against the "improvement" of wine by sugar of lead, etc., were promulgated by an imperial diet in 1475, by the Emperor Frederick III in 1487, and by Maximilian in 1497.

The penal ordinance of the criminal court directed its attention to the falsification of goods in a special section on "Falscher mit Mass, Wag und Kaufmannschaft," and their example has been followed in the modern German Empire. Beer, too, was kept under supervision, though this and other industrial productions were mainly controlled by the guilds.

Ordinances of medical police were issued in a few cities; one in Nuremburg in 1518 regarded the sale of food, popular amusements and adulteration of wine, a thing often done even by the ancients.

Early Rules Governing Autopsies.—Ordinances that came within the sphere of State Medicine existed even in the Middle Ages, Germans being among the first promoters. Autopsies were everywhere, made in cases of poisoning. Charles V enacted a criminal ordinance in the year 1530 that definitely determined the cases in which the judge should summon expert medical assistance. These were all cases of infanticide, mortal wounds, apoplexy, poisoning, concealed pregnancy and childbirth, abortion, the practice of medicine by incompetent persons, etc. However, in this ordinance judicial autopsies were not directed. They were opposed by every superstition, and it was not until 1562 that Paré made a judicial autopsy, after which postmortems frequently took place. It was from this time on that reciprocal action upon each other of medicine and jurisprudence became permanent.

The Founders of Medical Jurisprudence.—State Medicine in the seventeenth century occupied considerable attention of the physicians at that time. Many contributed works on this subject, others devoted special time and study to anatomy. In the early part of the century, the Pope's physician, Paolo Zacchias, wrote an independent work, renowned not only for its medical information, but especially for the legal knowledge it contained. Zacchias, I believe, is looked upon as the founder of legal medicine. Later, N. Blegny, Gendrie d'Angers and others, in France, wrote on State Medicine.

But to the Germans, during the seventeenth century, are we indebted for active cultivation of this department. Ludwig von Hoernigy, in 1638, published a work on the duties of the medical profession as a whole; Paul Ammann and Hieronymus Welsch wrote works on the mortality of wounds; Melchior Sebiz, in 1641, likewise wrote on this subject, and on the signs of virginity. John Friedrich Zittmann, Bernard Suerus and John Bohn, the latter the scientific founder of State Medicine in Germany, wrote on these subjects. Conrad Berth Behrens, ordinary physician to the court of Brunswick, and J. W.

Pfeizer, wrote on the duties of the forensic physician. The Hollander, Feltmann, expatiated on the examination of corpses, and John Brown on the mortality of wounds.

Active Growth of Legal Medicine.—During the seventeenth century numerous ordinances of medical police or hygienic ordinances were enacted. This period may be styled the natal era of State police, and the law included ordinances relative to plague, clothing, food, the inspection of provisions, etc.

In the eighteenth century, State Medicine was in high state of cultivation, especially in Germany. Those who are acquainted with the works of Fabricius, Buttner, Ploucquet, Valentin, Ludwig, Tropanneger, Buchholz, Schlegel, Daniel, Platner, Teichmeyer, Alberti, Eschenbach, Metzger, Pyl, Uden, Delius, Baumer, Frank, etc., know to what extent forensic medicine advanced in that country.

In France the learned Bellocoque, Prevost, Verdier, etc.; in Spain, del Valle, and in England, Farr—all are standard authors on State Medicine.

In the beginning of the nineteenth century Pater Frank introduced the official distinction of medical police and forensic medicine. He became the champion of hygiene and was followed by Hebenstreit, von Huszty, von Nassynya, Scherf, and others.

The part of State Medicine which deals with practical instruction in sanitary science has, in Europe, been prosecuted in varying degrees in different countries. To such work as that carried on by Parkes, Klein, Creighton, Sanderson, Baxter, Smith and others in England; to the investigations of Pasteur, Chauveau, Duclaux, Chamberland, and others in France, and to the bacteriologic investigations of Koch, and the chemical studies of Pettenkofer, in Germany, are we to attribute the present position of practical knowledge of hygiene.

In some countries the instruction of public hygiene is limited, being usually confined to a course of hygiene in some medical school. In others there are institutes of hygiene on the most extended scale, as, for instance, those at Munich, Leipzig, and Copenhagen. In Hungary the province of instruction in State Medicine is of an extended character.

Knowledge of Anatomy by the Ancients.—Autopsies and dissection are said to have been made hundreds of years before Christ. The Talmud thoroughly describes the anatomy, pathology, and physiology of man, speaks of the dissection of animals, and also of the human being, teaches how to skeletonize, and cites the case of a prostitute whose body was boiled and afterwards skeletonized. We also know of the two great anatomists, Erasistratus and Herophilus, in 300 B. C.

Early Dissections.—Dissections have been made in every century; always with opposition by the laity. There was no regulation law by which a medical student could obtain material to study the elementary of medicine. However, we find that in the fifteenth century Italy turned over her condemned criminals to medical colleges. It is related by writers that all condemned criminals of Italy were sent to Pisa for execution, and were frequently turned over to the anatomists of the University, who poisoned and then dissected them.

Human Vivisection.—It is claimed, in the History of Louis XI, that a human being was vivisected in France. It states that in 1474 a condemned robber was vivisected for the purpose of finding out where certain maladies were concreted, from which he and numerous other persons were suffering at that time. Opening and incision were accordingly done, the maladies searched for and examined, after which the bowels were replaced and the body was sewn up again. The patient's wound is said to have healed within fifteen days, and he was pardoned and given some money.

In the sixteenth century vivisection of human beings was charged against three men, viz., Berengar of Carpi, Vesalius and Fallopius in particular, and against the anatomists of the University of Pisa in general.

Berengar of Carpi is believed to have actually vivisected two Spaniards; Vesalius is accused of dissecting a Spanish nobleman, believing that he was dead, and Fallopius is said to have been his accuser. The following paragraph is found in the fourteenth chapter of his work, "De Tumoribus": "Fever resists 'colc' poisons, as I found at Pisa while anatomizing a man. For the prince commands them to give us a man, whom we kill in our own fashion, and anatomize. To whom we gave two drachms of opium, and an attack of agu; coming on (for he suffered from quartan) prevented its action. He, delighted, requested a second dose, and that we should intercede for his pardon if he survived it. We gave him another two drachms, when he had no attack, and he died." Such history sounds possible, but not probable; however, it is from this sort of history that the ignorant public, both European and American, have become prejudiced against medical colleges, and believe that human beings are dissected alive.

The regular legal inquest of autopsies and postmortems was first established in Austria, in the early part of the eighteenth century. It was soon followed in France through the influence of Gardanne, and in Germany through that of Hufeland.

The first judicially authorized dissection in the United States was made by Dr. Shippen of Philadelphia, in November, 1762. The case was that of a negro who had cut his throat with a glass bottle, from the effect of which he died; after the coroner's jury had pronounced him guilty of self murder, his body was immediately ordered, by judicial authority, to "Dr. Shippen's Anatomic Theater."

Laws on Dissection.—The first American anatomy law is the New York Act of 1789; since that time thirty-four States allow dissection; nineteen States have liberal anatomy acts, while fifteen have illiberal ones; the laws of eleven States are silent regarding anatomy, excepting their laws on malpractice; thirty-one States forbid the desecration of graves, while the laws of fourteen States are silent regarding either dissection and disinterment; none of the three territories allowed dissection.

Ignorant and preposterous opposition of pretenders has always been a snare to the study of pathology. The county commissioners in charge of the Chicago Asylum, in 1884, raised religious prejudices against postmortems, and were found to be selling the bodies to medical colleges at $30 each for private profit.

Opposition to Vivisection.—The progress of medical science, especially of physiology, biology, hygiene, etc., has called increasing attention to a higher degree of research in anatomy and physiology; to that end, vivisection of the lower animals is necessary.

At every session of legislative bodies of the various States in the Union, and of every country in Europe, an attempt is made, by a set of so-called "anti-vivisectionists" to influence legislators to enact laws against vivisection.

The fact of the matter is that vivisection is, un-investigators, a most misleading term to the laity. They seem to have the idea that animals are cut up alive by medical men, and compelled to suffer great pain for unjustifiable objects. A small percentage of the public know that anesthetics are administered beforehand and that the animal is killed before sensation returns, and that such experiments must be carefully made and free from pain, otherwise they would be useless.

Value of Vivisection.—The question, value and character of scientific research, when carried out on living animals, has in late years been aroused by an attempt on the part of the enemies of science to entrap the influence of those who profess better things.

No physiology can advance without vivisection, experiments on living animals are as essential to its progress as is dissection for the study of anatomy. The law of sacrifice is the law of life, therefore the law of nature, that one thing should be sacrificed for another. It is a common thing for a man to endanger his own life to save that of another. How many physicians, nurses, etc., have lost their lives while attending to the sick and wounded in infectious diseases and in war on the battlefields.

I maintain that any person who would deny the saving of a human life at the cost of a mere dog, cat, or rabbit, is a pretended humanitarian. For instance, a professor showed his students how he had saved the lives of several men by a certain operation on the brain. In order to demonstrate the operation he performed a *fac-simile* operation on a monkey, which also recovered. The professor, in his lecture, informed his pupils that before he ventured the first operation he performed it on a living monkey. Now, according to the opponents of vivisection, it would have been a lesser crime to have let several men die than to have risked the life of a monkey.

Vivisection Develops Sympathy.—Regarding the false idea that a physiologist takes pleasure in making animals suffer, I will say that instead of developing cruelty, the practice of physiology tends to increase in us the feeling of humanity and pity. The physician who has closely observed human suffering, instead of being hardened by it, becomes more compassionate. So the physiologists, who are acquainted with pain, are full of pity for suffering beings, and I do not hesitate to state that not one of them would be guilty of brutality toward an animal.

Our Debt to Vivisection.—Take away from the science of medicine and the art of surgery, all that with which physiology has enriched it, and the physician and surgeon of to-day would be no better than a mystery man or a quack vendor of chance-gotten drugs. Discard the present system of physiology, and all that has been gained by experiments on living animals, and the whole structure would collapse, leaving nothing but a few isolated facts of human experience.

The physiologic knowledge that we have and that we will gain in the future, if properly legislated in its favor, will benefit suffering humanity. The opponents do not stop to think that vivisection is as justifiable as the killing of animals for food. Physiology demands it for the good of all living creatures, and medical men should carry it out.

Moreover, I doubt if there is a single "antivivisectionist" who would miss a beefsteak for the sake of saving the life of a magnificent steer, or would deny himself of either a veal or a lamb chop in order to spare the life of a calf or that of an innocent lamb. Hundreds of millions of living creatures have already been sacrificed by epidemics, contagious and zymotic diseases, largely through the want of knowledge. It is unnecessary, therefore, to prove the utility and morality of vivisection. Nearly all physicians and all physiologists approve of it.

Vaccination.—As a prophylactic against dangerous variola, compulsory vaccination was established early in the nineteenth century. It was first made compulsory in Germany in 1807.

Austria, Prussia, and even Russia recognized the value of the vaccine prophylactic and made the practice general and compulsory throughout its territories in the early part of the nineteenth century.

In 1853 in England an Act of Parliament was passed making it a penal offence for any British subject to fail to protect himself by vaccination. In 1864 the American Medical Association at its fourteenth annual session, held at Chicago, appointed a committee to inquire into the expediency of a national law compelling every individual in the United States to be vaccinated. The committee reported at the fifteenth annual session, at New York, in favor of such a law, but came to the conclusion that general compulsory vaccination in this country, at that time, was impracticable, owing to the unpleasant condition of our nation at that period.

Tuberculosis.—But the time has now come when the medical profession should show the national supremacy, by their united action in demanding enforced national legislation for the protection of its inhabitants from infectious diseases by compelling every man, woman and child not only to be vaccinated, but also to take precaution against infectious tuberculosis.

Koch's first investigations revealed tubercle bacilli in the dust that had been contaminated by the sputa of phthisical patients, and the coma bacilli of cholera in the mud-banks of Indian water-tanks. Kitasto of Japan and other observers have found tetanus bacilli in the soil.

These and numerous other experiments have proved the presence of pathogenic microbes in the soil. Those investigations endured a great amount of experimental work under the auspices of various governments, such as France, Germany, Austria, England, Russia and the United States. The field of contagious animal diseases is in a much more advanced state, controlled, as it is, by the Bureau of Animal Industries, under the Department of Agriculture.

Tuberculosis Mortality.—According to statistics, tuberculosis kills one-seventh of all the population of the world, and one-third of all deaths occurring between the ages of fifteen and sixty years are due to tuberculosis. Furthermore, it destroys four and a half times more people than do smallpox, scarlet fever, typhoid fever and diphtheria combined; that in America 1,200,000 people have the disease at all times, or one in fifty persons.

Dr. Mullins of Sydney, Australia, reports, for a period of twelve years, 17,114 deaths from tubercular disease in New South Wales. Of these 12,430 were from phthisis, 2,241 from tabes mesenterica, 1,325 from tubercular meningitis, and 1,018 from other forms of tuberculosis. During the year 1898, in the State of New York alone, there were 12,979 deaths due to consumption; of this number 7,825 were in the city of New York.

Bovine Tuberculosis Transmissible.—Dr. Charles Creighton emphatically says: "I cannot escape from the conviction that the peculiar errors of nutrition in the domesticated bovine species all over the world are the real fountain and source of human tubercle."

A strong confirmation of the view that bovine tuberculosis is transmissible, at least to young children, is contained in the fact that the mortality of children under five years of age from primary tubercular ulceration of the intestines, and from tuberculosis of the peritoneum and mesenteric glands (tabes mesenterica), is very high.

According to bacteriologic investigation, the bacilli of bovine tuberculosis have been found to be identical with those found in tubercular formations in the human organs, although the disease is anatomically different in man than in cattle. These differences are considered due to differences of soil in the human and bovine tissues, the bacilli engrafting themselves in those tissues which present conditions most favorable to their growth and development.

It has been found that the milk of tuberculous cows containing tubercle bacilli, when administered as food, produced tuberculosis in dogs, guinea-pigs and rabbits.

What Statistics Prove.—Woodhead states that in 127 cases of tuberculosis in children examined by him he found tubercular ulceration of the intestine in forty-three; whilst in 100 cases, or nearly 79 per cent. of the whole, the glands connected with the intestinal tract were in some stage or other of tubercular degeneration. Woodhead contends that tuberculosis connected with the intestine is of frequent occurrence in children, infection frequently taking place by the alimentary canal.

It is a curious fact that wise men occasionally fall into errors, strange and unaccountable. I trust that the error recently made by Dr. Koch, at the British Congress of Tuberculosis, that bovine tuberculosis is not infectious to man, will not retard the action and movements of scientists against the dangerous infection from bovine tuberculosis. If Koch does not believe the identity of human and bovine tuberculosis, we will simply refer him to the observations of Tscherming of Copenhagen, Pfeiffer of Weimar, Law of Cornell University, Williams of the Brompton Hospital, Cozette of Noyon, France, and many others who report infectious cases of bovine tubercular infection.

Illustrative Cases.—Tscherming relates the case of a veterinary surgeon, who cut his hand while making a post-mortem examination on a tuberculous cow. Although the wound healed, a swelling remained, which became ulcerated and refused to heal. Eventually, the whole mass was removed, and microscopic examination revealed the presence of tubercle bacilli. Pfeiffer relates a similar case of a veterinarian, aged thirty-four, of good constitution and free from hereditary taint, who wounded himself deeply in the left thumb. The wound healed, but about six months afterward a cutaneous tuberculosis was diagnosed at the site of the scar. A year later the patient manifested undoubted signs of pulmonary tuberculosis; the sputum was found to contain tubercle bacilli, and the patient died two and a half years after receiving the wound. Post-mortem examination revealed tubercular arthritis of the wounded thumb, and extensive tubercle and cavities in the lungs.

Law reports another case of a veterinary surgeon, who was wounded in the hand while operating on a tuberculous cow, and suffered from a tumefaction of the resulting cicatrix, with distinct tubercle bacilli. The tumefaction was surgically removed, and was evidently the means of saving the patient from a generalized tuberculosis

Cozette, a French veterinarian, relates where a consumptive attendant had infected two cows, which, when handed over for slaughter, were condemned because of their markedly tuberculous condition; however, those two had infected seven others, who became ill, and were killed. Autopsies demonstrated clear cases of tuberculosis.

Law cites the case of a healthy child, aged one and a half years; while at a relative's house for one week it drank the milk of a cow which soon afterward was condemned and killed. Autopsy revealed generalized tuberculosis. The child gradually emaciated, death occurring three months later from abdominal tuberculosis.

Professor Gosse of Geneva cites the case of his own daughter, who died from intestinal and mesenteric tuberculosis, which he attributed to the milk the girl drank daily, fresh from five cows, on his estate. They were all slaughtered and two of them showed tubercular disease of the udder.

Demine of Berne reports the case where four infants in the Hospital Jenner, whose parents were all healthy, with no tuberculous history, died of intestinal and mesenteric tuberculosis as the result of drinking the unsterilized milk of tuberculous cows.

Brouardel likewise records a case where five out of fourteen young girls, living together in a boarding-school, became consumptive, subsequent to the daily use of milk from a tuberculous cow. We could cite hundreds of similar cases to convince our friend Dr. Koch of his mistaken ideas of bovine tubercular infection.

Now, if the lactile secretion is infectious, there can be no doubt that the meat from animals which suffer from even a localized tuberculosis is not fit for human consumption; furthermore, we have ample proof that a localized tuberculosis will naturally find its way into the muscular structure or other parts of the carcass used as a food; therefore, such meat should and must be condemned.

Importation of Diseased Animals.—Most all civilized countries have and should have some laws for the prevention of importation of epizootics by foreign live animals. Limited space and other considerations naturally prevent long periods of quarantine or observation and detention of those animals intended for exhibition or reshipment, or for other special purposes. Many infected animals are slaughtered at the port of arrival, and suspected live animals are frequently excluded.

In 1848 the English Legislature employed numerous means to prevent the importation of sheep, cattle and other animals suffering from contagious or infectious disorders, and gradually further powers were granted until their consolidation and perpetuation in the Contagious Diseases (animals) Act of 1869. Great devastations continued as the result of epizootics, and serious legislative efforts were made until again codified in the existing Act of 1876, to which amendments were added in 1884, 1886 and 1890; so that, as in certain human communicable diseases, the contagious diseases of animals are also subject to compulsory declaration, isolation, and disinfection, with the additional powers of prohibited importance, quarantine and slaughter.

Governmental Control—In July, 1891, a congress for the study of tuberculosis in man and animals was held at Paris, and the following resolutions were passed:

"It is necessary that all governments should decree the most efficacious prophylactic measures for preventing the extension of bovine tuberculosis.

It is perfectly necessary to establish a special inspection of meat in all towns, without exception, provided with a public abattoir. It is equally necessary to suppress all private slaughter houses in towns possessing more than 5,000 inhabitants, and to replace them, as soon as possible, by public abattoirs; effectual inspection is impossible without this measure."

Tuberculous subjects, man and beast alike, should be subject to quarantine restrictions, and the control should be part of the duties of either a national, state or municipal board of health.

The expectoration of sputum of tubercular patients should be prohibited in public places, public vehicles and even on the highways. If the oral secretion is infected with tubercular elements and dries on the floor it is likely to pulverize and float about as dust, thus inhaled, it is a means of spreading tuberculosis. It may be difficult at first to enforce such an ordinance but a law of this sort will certainly have a moral effect, and eventually an educative action on the public who will consider it indecent and disreputable to spit in public places. It will likewise educate the public to look upon public spitters with contempt.

The National Board of Health, which was established in 1878, was appointed and supplied with grants by the Federal Government, which enabled the board to institute investigations of great importance regarding the causation of disease, etc., has unfortunately, through political prejudice, withheld its influence, so that very little practical work has been done, and was finally abolished. But the Marine Hospital service, with the late Dr. John B. Hamilton and the present Dr. Walter Wyman at the head of that department, protected the country against foreign importation of infectious and contagious diseases.

Tuberculosis Sanatoria.—S. A. Knopf of New York, before the conference of the State and Provincial Boards of Health of the United States, delivered an address upon the State and municipal care of consumptives. He believes that a commission should be provided for the examination and care of tuberculous subjects, to determine their physical condition, to investigate their surroundings and the danger to their families; to render their homes sanitary if possible, and, if necessary, to endeavor to remove the patients to an institution. Anyone should have the privilege of being examined, and all physicians should have the privilege of recommending patients for examination. The institutions for the care of these individuals should comprise a reception hospital and dispensary, located in the city; a surburban sanatorium, in an elevated region, if possible, this to be used as a temporary hospital for patients subsequently to be sent to a mountain sanatorium, which should, if possible, be elevated from 1,000 to 2,000 feet above sea level. There should also be seaside sanatoriums for the treatment of children with tuberculous disease of the joints and glands, and a maternity sanatorium.

Knopf also quotes the greatest authorities of the world, who are in favor of such a movement—Dettweiler, Leyden, and Liebe of Germany; von Schrotter of Austria; Grancher, Letulle and Petit of France; Weber, Lindsey and Sangmann of Denmark and Sweden; and in the United States, Bowditch, Hamilton, Biggs and Prudden, Lee, Trudeau, Flick, Hinsdale, Otis, Shrady and others, all strong advocates for the establishment of State and municipal sanatoria for the care and treatment of the consumptive poor.

The crowned heads of Europe, such as the Czar of Russia, the Emperor of Austria, the King of Saxony, the King of Sweden and the young Queen of Holland have placed the sanatoria for the consumptive poor under their high protection and have opened their private purses for their support. The nobility and the leaders in finance, art and literature have been eager to imitate the noble example set by their sovereigns, and the latter, too, have given freely toward the erection and maintenance of such institutions.

Thus in the countries just mentioned, a number of establishments now flourish which are doing a world of good by curing the curable tuberculous cases and taking care of the hopeless ones, thus diminishing countless centers of infection.

Dr. Knopf justly says: "Let me further advise the statesman, physician or philanthropist who doubts the need of such institutions in the United States to visit the consumptive poor in the tenement districts of our large cities, and study the hygienic and social conditions of these sufferers in their surroundings."

National Board of Health and Examiners.—It is the duty of every citizen, as well as of the physician, to insist that our National Congress establish a medical bureau of the Department of the Interior, for the purpose of regulating the various professions that battle for the welfare of suffering humanity.

First, to establish a federal board of medical examiners, under the auspices of a medical bureau of the Department of the Interior, so that any physician, dentist or pharmacist may follow his profession in any part of the United States, or in any of its territories, thus granting the privilege to its citizens to invite a physician or dentist from any part of this country to ameliorate their sufferings.

Second, under the auspices of the same bureau, there shall exist a national board of health, consisting of men of learning and ability, competent to make bacteriologic and chemical examinations for the purpose of preventing the spread of the various contagious and infectious diseases, the adulteration of food, and the sale of infected cattle, and to restrict the sale of the so-called patent medicines.

Third, the bureau shall have jurisdiction over the registration of births and deaths, census and vital statistics in general.

Regulation of Marriage.—It is also desirable to have a national law pertaining to marriage and divorce. The unfortunate conditions of either, each State having its own laws, demand immediate action of Congress for the regulation of this evil.

Marriage should be prohibited to blood relations up to the second degree, and to all persons of either sex affected with either congenital or acquired specific or infectious disease, such as venereal or pulmonary affections, confirmed drunkards, criminals, anarchists and degenerate classes.

Each applicant for a marriage license should present a certificate from a medical examiner, appointed for that purpose, stating that the applicant is not affected with any disease or habit that would be derogatory to procreation or offspring. When parents are tainted with specific disease, it is almost invariably looked for and expected with the children. A taint of hereditary drunkenness, insanity, suicide, epilepsy, idiocy, deaf-mutism, cancer, syphilis, gout, rheumatism, tuberculosis or scrofulous diathesis in the blood, are all symptoms of degeneration, likely to be intensified by propagation in succeeding generations, until the tainted family becomes extinct. Intermarriage with those tainted diffuses weakness, deformity, and abnormality through the social structure, deteriorates and contaminates all who issue from such unions.

Intermarriage of distinct diseases are as dangerous as the union of two consumptives. A typical case, cited by Richardson, will corroborate this statement: "A young man, of marked cancerous proclivity, married a woman whose parents had both died of pulmonary consumption. This married couple had a family of five children, all of whom grew up to adolescence, sustaining at their best but delicate and feeble existences. The first of these children died of lupus; the second of simple pulmonary consumption; the third, owing to tuberculous deposit in the brain, succumbed from epileptiform convulsions; the fourth, with symptoms of tuberculous brain disease, sank from diabetes, the result of the nervous injury; and the last, living longer than any of the rest, namely, to thirty-six years, died of cancer. The parents in this instance survived three of the children, but they both died comparatively early in life; the father from cancerous disease of the liver, the mother from heart disease and bronchitis."

While we have some States prohibiting consanguineous unions, there are others that have not kept abreast with modern civilization, and allow the marriage of near kin. There is not a physician who is entitled to that name who does not know the physiologic reason for prohibiting consanguineous marriages; but for the benefit of those who do not know, I will state that besides degenerations, a marriage between persons closely allied in blood is apt to produce an offspring feeble in body and a tendency to insanity in mind.

As to confirmed drunkards, I can only repeat what Plutarch says—"One drunkard begets another;" and Aristotle adds: "Drunken women bring forth children like unto themselves." Dr. Howe, in a report to the Legislature of Massachusetts, says, "The habits of the parents of 300 of the idiots were learned, and 145, or nearly one-half, are reported to be known as habitual drunkards." Howe cited a case in which the parents were drunkards, and had seven idiotic children.

Prophylaxis against Anarchy.—Another dangerous disease with which the world has to contend, and which has lately shocked our nation, and, in fact, the whole world, is anarchy. The murderous assault upon the President, aimed as it was at the life of the government, imperiled the security of the whole country. The right of self-preservation is as vital to the State as to the individual.

The entrance of foreign anarchists must be strictly prodibited as well as other infectious matter. Their teachings are as poisonous as the bite of a snake, and as dangerous as the swords and bayonets of a hostile nation. The pestilence of the teachings of the anarchists who dwell amongst us cannot but have influence upon their offspring; therefore there must be a law preventing their marriage. The characters possessed by an individual are mainly congenital, peculiar to each individual in type and variation; therefore, the offspring bear a typical likeness and character to the parents.

Criminals and murderers may regret and repent their crimes, confess and receive absolution, and, after their execution, may go direct to heaven, but society is better off with such individuals in heaven than on earth.

A great deal can be said in favor of a national law of divorce. But what mainly interests us is the medical portion. According to medical jurisprudence, impotence in man and sterility in woman, or any impediment to procreation of children, is absolute ground for divorce; however, what we desire to add is that specific and infectious disease endangering offspring shall likewise constitute grounds for divorce.

Public Baths.—The public bath is another necessity to municipal hygiene. The ruins of the caracallas of Rome speak clearly of the glorious bathing establishments of the fifth century; though in a state of decay, yet they show the inclinations and habits of the people who prevented municipal filth. It is said that Rome had at one time 856 public baths. In the middle ages nearly every village and town is said to have had its bath-room with wooden tubs. Russia, Turkey and Japan are renowned for their public baths, which are accessible to the poorest classes upon the payment of a very slight fee.

France, Belgium and Austria have kept apace with other countries. The United States, unfortunately, has done very little towards this hygienic problem. The only baths provided in this country by municipalities are a few floating or swimming baths in New York and in Chicago. The New York baths were authorized by the Legislature of that State. About twenty such establishments exist in that city to-day. Another act in the Empire State, in 1892, authorized any city, village or town in the State to establish public baths, and to loan, credit or make appropriations for that purpose. I trust that the great State of New York will continue its good work, and that other States will follow. It is admitted that if you deprive a man of his bath you lower his moral tone. "Soapology" and "scrubology" as well as "theology" are recognized by General Booth of the Salvation Army as potent Christianizing agencies.

Restriction of Venereal Diseases.—Compulsory examination of prostitutes is another necessity for the purpose of preventing the spread of venereal diseases. It is said that either the City of New York or Chicago contains, at the present day, venereal infection sufficient to contaminate the male population of the United States in a very short space of time.

We do not want legalized prostitution as it exists in European countries. I do not believe in authorizing houses of debauchery and making of prostitution a regular profession. The State has no right to regulate prostitution. I am proud of my country, which is, fortunately, free from the incubus of State-regulated vice.

All that is desired is a State law for municipal governments, to keep a register of all women known or suspected of prostitution, and that such women shall be liable at any time to be called in for examination. But no certificates should be issued to them, as to their healthy or unhealthy conditions, for such a certificate would simply encourage the vice. However, if found affected with a venereal disease, they should be sent to a detention hospital or sanitorium, and should be detained there until cured.

Detention of Syphilitics.—I firmly believe in the law of Massachusetts, for the detention of certain persons affected with syphilis, in which it is enacted that persons suffering from syphilis, and being inmates of any correctional or administrative institution, such as a house of correction, a penitentiary, or a work-house, shall be placed under medical treatment, and be isolated until the medical attendant shall consider further isolation unnecessary; and if, at the date of discharge of a person, syphilitic symptoms are still present, likely to prove a public dan-

[illegible] compulsory [illegible] must be sent in force to retain the infected person until such a time as dangerous symptoms have been pronounced to be no longer present.

A suitable hospital or sanatorium devoted to the cases peculiar to prostitutes should be established in each and every city, with the power to place and keep them all without a discharge until cured. The amount of accommodation required should depend upon the size of the population and there should be at least one bed to every 1,000 inhabitants. Payment could and should be required from all who possess the means of expense actually incurred and this would contribute a considerable sum towards the expenditures of such an institution.

It should not be intended as a prison, for such is directly contrary to reformation. Liberal arrangements as a hospital would afford no encouragement to vice, and certainly help wonderfully to eradicate the evil.

Abolish the Coroner.—There is one law, a relic of barbarism, that I should like to see abolished, and I know that the profession would heartily approve of it, that is, the office of county coroner; and in its stead a medical examiner should be created. Such a law was established in Massachusetts about fifteen years ago, and gives great satisfaction from both a scientific and financial point of view.

Conclusions.—All foregoing regulations, if established, will, I am sure, tend to improve the moral and physical welfare of our nation.

State Medicine is a creation of necessity in times of public danger, but its future development will be in proportion to the scientific character of its work, and to the appreciation on the part of the public of the economic and beneficent results of such work.

The world's rapid transit and intercommunication brought on the high state of civilization, and made the whole human race one family, so that people of every color, clime, language, government, and creed have become one brotherhood, with a law of love and care for one another which fulfills the golden rule—"love your neighbor as you do yourself."

SUTURE OF HEART WOUNDS.*

By HARRY M. SHERMAN, A.M., M.D.,
SAN FRANCISCO, CAL.
PROFESSOR OF SURGERY, MEDICAL DEPARTMENT OF THE UNIVERSITY OF CALIFORNIA; SURGEON TO ST. LUKE'S HOSPITAL; ORTHOPEDIC SURGEON TO THE CHILDREN'S HOSPITAL.

The Recorded Sutures of the Heart.—In 1896 three operations for the suture of wounds of the heart muscle were done. Two are recorded as having been done in 1897. Four are credited to 1898. In 1899 the heart was sutured eleven times, in 1900 three times, and in 1901 nine times, three of this last set being done in this country. This year two operations have thus far been reported. This makes a total of thirty-four operations in the six years following the first attempt to treat, by a simple surgical procedure, an organ usually supposed to be particularly vulnerable—in fact, so vulnerable that any interference, even for surgical purposes, might be followed by immediate fatal results.

There is more than enough material here for our consideration at this time, and I beg you to follow me in the necessarily brief discussion which I offer you.

In order to start with some knowledge of the results of these operations, before any discussion, in general or in detail, is attempted, a short review of them will be necessary.

Review of These Cases.—As regards the manner of wounding, all these cases, except two, were due to punctured or incised wounds, the two exceptions being bullet wounds. The particular injury to the heart was inflicted on the ventricles thirty-two times, the left ventricle being implicated seventeen times and the right thirteen times. In two cases only were auricles opened, once the right and once the left, and there are three cases in which my information is incomplete. In most of the cases where details are given the pleura is reported wounded, and usually there was a hemothorax, the collection representing, in large part, the overflow from the pericardium.

The practical questions which usually come to the mind of a surgeon in planning an operation to meet these conditions relate to the method of exposure of the heart, the detail of the treatment of its particular condition, and the method of closing and dressing the wound of the operation.

In the cases reported the heart was reached variously, depending on the location of the original wound in the skin and the choice of the operator, but either a flap of all of the tissues of the thoracic wall was turned up, or a resection of two or more ribs was practised. The particular detail is of no great moment, provided that the heart is properly exposed. The special method of treating the heart wound is of interest, for it involves the choice of suture material for a novel situation, the time at which the suture is introduced and tied with reference to the heart beat, and the depth of the stitch in the heart muscle. In our cases three operators are recorded as having used catgut, Fontan of Paris, Marion, and Launay; in all other instances where the suture material was specified silk was used, and in most cases the sutures were interrupted, though in a small number a continuous suture was practised. It is of interest to note that these operators particularly avoided including the endocardium in the suture. One of them definitely reports introducing and tying the suture during diastole.

As regards the closure of the wounds—the tissues involved in the flaps or incisions were, of course, replaced; in seven instances drainage of the pericardium and pleura was practised, and in four the pleura alone was drained. The other cases are said plainly to have been closed without drainage, or nothing is said of the matter at all.

Results of These Cases.—Now, of the total number of these cases five died on the operating table of hemorrhage, and ten died very soon afterward of the effects of hemorrhage or the shock of the operation; so that nearly half of the cases that survived the injury long enough to be subjected to operation died during or very shortly after that operation. The other group, nineteen in number, had various fortunes, but thirteen of them recovered and only six died. I think it is fair to stop a moment and consider these facts. Surely the fifteen who died of hemorrhage or shock with operation would probably have died of hemorrhage exactly the same without operation. No fatal traumatism is inflicted by exposing the heart; and stopping the hemorrhage from an incised or punctured wound in the ventricles is a simple matter when the heart is once exposed, indeed, pressure with the finger or a tampon will stop it temporarily. At all events the operation and suture did not add materially to the amount of blood lost and so cannot be counted as having hastened the death from hemorrhage, and the average amount of shock I cannot estimate. But I believe that it is fair to say that these patients had, from the first, practically no chance to recover, and that if this had been known, the operations need not have been done—but I say this with full appreciation of the fact that the inevitable fatality could not have been definitely predicted in any case. Of the other nineteen, the comment is, plainly, that they had a chance to recover. In each of them the suture of the heart was a successful procedure; in not one instance was the fatal outcome due to a secondary hemorrhage. The six who died succumbed to the common matter of an infection, sequent to wound and operation. Of the thirteen who recovered four did so in spite of a concurrent infection. But the point is that of these thirty-four cases, fifteen had, really, but very slight expectation of benefit from the operation and died, probably, neither in spite of it nor because of it—nineteen had expectation of recovery from operation, and in thirteen that expectation was realized.

---

*Oration on surgery delivered before the fifty-third annual meeting of the American Medical Association at Saratoga Springs, N. Y., June 10–13, 1902.

I do not wish you to think that I am trying to make these cases give a better percentage of recoveries than they really do. That percentage, as the whole list stands now, is about one-third. But if we wish to consider only the final success or failure of the suture of the heart muscle we must limit our inquiry to the cases in which this procedure was really tested, and then we see that the percentage of recoveries may be considered a little more than two-thirds.

Slow Advance in Heart Surgery.—The road to the heart is only two or three centimeters in a direct line, but it has taken surgery nearly 2,400 years to travel it, for I take it that the operation of opening the chest for an empyema, which was known to Hippocrates, was a direct predecessor of the attempt to treat other thoracic viscera. It does not need to be said that during most of this time surgery stood still and that the advances were little by little. We all know that before the antiseptic and aseptic eras pleurotomy for empyema gave very terrible results, and there could be but scant encouragement to draw surgeons to fresh fields. However, more than a century ago (1798), Desault, with the logic and precision which still characterizes the French school, laid down the rules for opening the pericardium for an empyema situated in that sac, and anticipated much of the technic of to-day, and it took surgery ninety-eight years to pass from the pericardium to the epicardium across a space that is such only potentially.

It is a little odd that surgeons have hesitated so long to go to the aid of the wounded heart in man. Physiologists for years have experimented on the hearts of animals selected from nearly all the species of the animal kingdom. The special references to this matter are not needed here, but it is germane to the subject to note that the tolerance of the mammalian heart for manipulation, and its persistence of action in spite of wounds and obstacles, have long been known.

The experience of the various operators has been, as might therefore have been expected, that the heart of man was no more resentful of intervention than were the hearts of other mammals, and that it not only could be handled, and even partially lifted from the pericardium, but that its muscle could be sutured so as to close a wound, just as can be done with the skeletal muscles. However, in the case of the systemic muscles rest can usually be enforced, either completely or partially, during the process of healing, but this cannot be done with the heart. Here comes the great difference between the heart muscle and the skeletal muscles, both as regards suture and the reparative process, the heart must continue to act for the whole of the time.

The question now centers, first, on the possibility of properly suturing, that is, placing a practical suture in the moving heart, and second, on the result of the healing process. The first question is one of only technical moment, for the work on animals has shown that it can be done, and the experience of those who have sutured the human heart has not disclosed any special difficulty in the procedure, but the matter and manner of the sutures are debatable. The general advice is that the sutures of muscle should be of silk, and it has been most frequently used in the heart muscle, but three of the successful cases, the two of Fontan's and the one of Launay's, were sutured with catgut. Elsberg has advised, as the result of his experiments on rabbits and dogs, that the suture material should be silk, and that the suture be an interrupted one, and very superficially placed, believing that deep sutures will tear out while superficial ones will hold. He also advises that the suture be placed and tied during the diastole of the heart.

Experimental Research.—To discover, if I might, the exact value of these somewhat confused matters, I have exposed the hearts in eleven dogs, and made wounds of various sizes and in different directions in the left ventricle, limiting myself to that particular cavity, as it was the one most frequently wounded. In each instance, except perhaps one, I verified the opening of the cavity of the ventricle by passing an instrument into it so as to get a free spurt of blood during one or two systoles. It was found that this verification was a practical necessity, for the non-penetrating wound of the myocardium will give forth, during systole, a spurt so large that it could easily be confused with one from the cavity of the ventricle. These wounds were then sewed with ordinary commercial cumolized catgut; in some deep and superficial stitches were combined; in some very deep, so as to surely penetrate the endocardium, were used, and in others very superficial stitches; and the variations of interrupted, continuous and recurrent continuous were practised.

In the earliest operations toothed thumb forceps were used to pick up a few muscular fibers to steady the organ for the making of the incision and placing the sutures. At the first pinch the heart, of course, delayed a systole and then began to beat rapidly and violently and continued this as long as the forceps were in place. It was exactly as if the heart were surprised and at first checked by the intrusion of the forceps' teeth, and then recovered to make violent and strenuous efforts to escape from the grip, and if the forceps' hold was continued it usually succeeded in this by the tearing of the fibers. One of my dogs died on the table from hemorrhage due to the tearing of the muscle in the bite of the forceps and my inability to at first catch the edge of the open wound in the bottom of a pericardium overflowing with blood, and, although I did finally succeed in getting in two sutures, they were placed too late.

A Method to Hold the Heart During Suture.—To overcome this difficulty with the forceps I put into the heart, before incising it, two long suspension loops of silk, dipping the needle carrying them deep into the ventricular wall. These gave complete control of the organ, for they did not tear out, and even though the heart was hanging from them its function continued, and much less tumultuously than it did in the bite of the forceps; and with them the heart could be lifted quite halfway out of the pericardial incision, or it could be swung to one side or the other, or rolled over in either direction, its range of motion being limited only by the great vessels at the base.

I placed these loops side by side and about a centimeter apart, and could then make between them, hold the wound open, by traction on the loops, to verify penetration and then crossing the loops, could absolutely stop bleeding and steady the heart. For under this control the point of the suture seemed to be the starting point of the systolic waves.

Diastolic Suture Unnecessary.—Now even with the motion interrupted and held relatively motionless by the crossed and taut suspension loops, so that the placing of a suture was no more difficult than in a different tissue—I found it impracticable, yes, impossible to make a diastolic thrust of the needle, to pull the suture into place in the succeeding diastole, and to tie the knots in the one following. To do this would require a man to work with accuracy, and yet with perfectly timed breaks in his work, in various fractions of successive seconds—for these hearts are always beating more than 100 times to the minute. And the impossibility which I encountered has made it very difficult for me to believe that anyone, even if he has attempted it, has ever really done it. Nor can I see what is gained by it.

The heart does not bleed in diastole, it bleeds in systole, and the suture must be tied to be efficient at that time, and the way to do it is to tie quietly and firmly, during the rapid beating of the heart, and to take no account of split second diastoles, but watch the knots as one should watch the knots of the ligature in a major vessel. And the same judgment which controls the tension of the suture should control the depth to which it reaches. I cannot agree, from what I have seen of the actual working of the matter, that a superficial suture will hold where a deep one will tear out. One is suturing the myocardium, not the epicardium. Of course, it is inadvisable to penetrate the endocardium, but it is, at the same time, and fortunately, a difficult thing to do. I did it once because I intended to do it, and I had to take a larger needle than I had ordinarily worked with, and definitely carry it through the heart wall and return; and from this I learned that, with the medium-sized full-curved needle, which one would commonly use, the penetration of the left ventricle is not to be feared.

On this point it only remains to be said that, in the case in which the endocardium was included in the stitch, the strand of suture stretched across the cavity of the ventricle was the occasion of the formation of a little globular clot, which was found at the autopsy to be firm and white, and surrounded by a large post-mortem clot.

Elsberg's very complete studies of the healing process showed that the muscular fibers in the bight of the suture atrophy and are replaced by fibrous tissue, and he points out that, very evidently, there would be less of this lower grade tissue in the case of an interrupted suture, but, so far as I have been able to judge, the difference amounts to very little practically, and the saving of time in the continuous over the interrupted suture is manifest, and it is the method finally advised by Terrier and Reymond a year ago. I had thought that the lessening of the number of knots on the epicardial surface by the use of the continuous suture might be a special point in its favor, but the matter seems to be unimportant, for all knots quickly sink into the tissues, leaving a flush surface, which is covered with fibrin.

Causes of Death.—For my experiments I have used dogs principally because of the size of the heart in the larger dogs—and I had the same difficulty that other experimenters have had with the animal, for there is no mediastinum, the whole thorax being lined by one continuous membrane, and as soon as this is opened both lungs collapse so that artificial respiration by bellows is needed. There are two important points in connection with this fact: a very large serous surface is exposed to the air and to infection, and it is practically impossible to avoid leaving a certain degree of pneumothorax when the chest is closed. Collateral traumatism and infection then led to the early death of most of the dogs; indeed, only two lived ten days and then both died of empyema and pericarditis. This makes it impossible for me to speak as confidently regarding the catgut suture as I should like, for a priori I should prefer in this place the absorbable suture, because a stitch once in is there to stay, and the opportunity of going back and removing it, if its presence is resented by the tissues, cannot be looked for. Still it is to be noted that one operator, Fontan of Paris, has the distinction of having twice sutured the heart with the recovery of both patients, and Launay has successfully closed two wounds in one heart, the suture material in all three cases having been catgut; and on the other hand, Nietert of St. Louis has also two successful heart sutures to his credit, his suture material being silk. Still, if it can be shown that the healing process takes place to a practical extent during the persistence of the catgut, it will be reasonable to argue that no great objection can lie against the absorbable suture. In Elsberg's paper he asserts that reparative processes are in train in twenty-four hours, in forty-eight hours there is a dense round-cell infiltration, by the fourth day spindle cells appear, by the seventh day they replace the degenerated muscle fiber, and by the tenth day the granulation tissue is becoming fibrous tissue. He reports several rabbits killed on the fourteenth day, with the wound in the heart firmly healed, and in one instance a rabbit, dead of sepsis, had a firmly closed heart wound on the eighth day. In two of my dogs, both dead of sepsis on the tenth day, the heart wounds were firmly closed, with no evidence of leakage or hemorrhage, although in one the infective process had attacked the epicardium and penetrated the myocardium. It does not need to be said that these dogs count for very little, but the inference is simple, from the whole evidence, that wounds of the heart muscle heal very rapidly, and that the process may be practically completed quite within the life of a catgut suture. And the evidence of Fontan's two patients, one of whom was infected, and Launay's case of two wounds in one heart, is on the same side, and I shall therefore assume that catgut is, at least, a permissible suture material.

Success of the Closure of Heart Wound.—Finally, it has to be said that in my dogs these sutures, however placed or tied, always controlled the hemorrhage and closed the opening, and that the healing processes, as they were studied, followed a course practically similar to that in Elsberg's experiments on rabbits, up to the death of my animals. They show that the repair in heart muscle is in no way different from the repair in skeletal muscles, and that it is no more interfered with by the action of the heart than are the nutritive processes of the organ.

I do not know of any of the successful cases of heart suture in man having died later, but there is reference to a case of Izzi's, in which the heart was wounded but not sutured and the man recovered, but on the twenty-eighth day, having left the hospital he made considerable effort to lift a weight and had rupture of the cicatrix in the heart wall and sudden death. Of course, the wound in this heart had been filled by a coagulum, and in the process of healing this was organized or replaced by cicatricial tissue, and there had never been the proper coaptation of the heart muscle in the edges of the cut.

So far as the heart itself is concerned the proposition for its suture, in case of wound, is properly established; and if it were a superficial organ and easy of access, and if the path by which it is reached could easily be closed again, the whole matter would be eminently simple. The operation would be more frequently done, for the occasions demanding it would more frequently arise, and the whole technic would be quickly worked out in detail. But the heart, while it is close to the surface of the body at one point, is not a superficial organ, and to reach it the bony and muscular hest wall has to be traversed—a matter of no special import—and two serous sacs have to be invaded. Herein lies the great difficulty.

Interference of the Pleura.—It is true that in a dissection the pericardium can usually be reached without a wound of the left pleura, but it can only be done by taking the pleura definitely into account. The anterior limits of the sac are very various and in the dissecting room it has been found to extend across behind the sternum almost to the right border of the bone. Commonly, it overlaps and lies just internal to the left border of the sternum as far down as the fourth cartilage, and from this point gradually passes downward and outward, crossing the sternal end of the fifth cartilage, and just internal to the middle at the sixth. A wound, therefore, to reach the pericardium and heart without injuring the pleura would have to be placed in the sixth interspace and close to the sternal edge, and be directed almost exactly backward. This place is so small that practically it is never found, and it is necessary to consider that all wounds which penetrate the pericardium have traversed the pleura, and it is across the same tissue and sac that the surgeon must pass who attempts to repair the wound. There is another point to be considered here. The opening of a serous sac, either accidentally or surgically, exposes it to infection, and the serous membrane, by a power inherent in it, deals with such infection as occurs unless the latter overwhelms it. The question has been thoroughly studied by all, in its relation to the peritoneum, but I wish merely to refer to the fact that the peritoneum offers opportunities for the localization of an infection which cannot otherwise be disposed of, and that intestinal rest may contribute greatly to this localization. Both the pleura and pericardium differ from the peritoneum in this respect—the surfaces of neither offer pockets or recesses in which an infection may be confined, and constant motion incident to breathing and the heart beat, tends to disseminate pathogens and to quickly distribute them over the whole surface of the sac.

So far as the arrangement of the lymphatics of the pleura is concerned, its power of absorption should be greater than that of the peritoneum, and in certain cases of infection, as in the empyema of pneumonia, it does show considerable ability to deal with the condition; but, in view of the great frequency of infection of the left pleura in connection with heart wounds, I am obliged to believe that the inability to obtain surgical rest for the tissue is a prominent factor in producing and perpetuating the condition.

In writing on wounds of the pleura and lung, Terrier and Reymond claim that infection of the pleura is not likely to occur unless there is a coincident wound of the lung. They argue that the infection, probably, comes from a bronchus, and base the treatment necessary for a traumatic hæmothorax on the presence or absence of hæmoptysis. In no one of the clinical histories of these heart wounds which I have seen is there mention of homoptysis, but they nearly all had hæmothorax, large quantities of blood being in the pleura, and a large percentage had a subsequent infection.

Sepsis and Drainage.—Of the thirty-four cases nineteen lived long enough for the development of an infection, and in ten it developed, and of these six died, showing that infection so affects prognosis in these cases that a man infected has not so much as half a chance to recover; or, to put it differently, more than half of the cases were infected, and of these more than half died. It is of particular interest to know the time of the implantation of the infection, and I have found records of nine other cases of wounds of the pericardium and heart which were not submitted to any primary operation, and of these three had local infection, and one had primary local healing but died of a peritonitis. The number of cases is very small, but so far as they go they show that about one-third of them are infected by the wounding instrument and that primary operation increases the chance of an infection to more than half; this, however, must not be taken as counting against the doing of the operation, for its object is to control conditions which lead to certain death, and even with an infection recovery is not impossible. The knowledge of the great likelihood of an infection at the time of the receipt of the wound must be made use of, and one must consider if such a wound is not to be treated as one already infected. If this is done some method of drainage will be employed, and the detail of its arrangement is complicated by this fact, that one serious sac, the pericardium, must be drained across or through another, the pleura. The advice is given, probably in view of this difficulty, that both pericardium and pleura be closed without drainage, but some operators have drained and their results merit consideration. So far as I can learn, eleven of the thirty-four cases had primary drainage arranged, four for the pleura alone, and seven for the pleura and pericardium. Of the eleven seven recovered though two had infection. Of the four who died two died of sepsis, and two of collapse before the possibility of knowing if sepsis was to develop or not, and if we exclude these last two we have nine cases drained and seven recovering.

Now, on the other side, there were nine cases that had no primary drain, and did have infection, and of these five recovered. The number of cases is small, seven out of nine and five out of nine, but in these cases as in many others, a hair, perhaps, divides the chances of success from those of failure, and where we have only small statistics at hand it is with those that we must work, and on them base our future actions.

In the drainage of the pericardium there is a point worth mentioning. The material should, of course, be gauze, it may be put in a small space left unclosed at the lowest point of the wound (Mignon et Sieur), and it does not need to go deeply into the sac, for with the patient supine or reclining the heart will sink in any effused fluid toward the dorsal side of the sac, displacing the fluid toward the ventral side, where a drain may easily reach it; but the fluid must pass upward from the pericardrop toward the exit opening, and this is of course a disadvantage. For the pleura a drain may be arranged to make its exit by the same opening as that for the pericardium, or, and this seems the wiser plan, it may have an independent opening near the posterior axillary line, where it will be of most service if empyema does develop, and may, in such a case, obviate the need of a secondary thoracotomy. Of course if no sepsis supervene all drains should be very shortly removed.

Other Points to Consider.—In the time allotted this paper on the program of the association it has only been possible to discuss the two technical points of suture and drainage, and the matter of the symptoms and the anatomic detail of the wounds which have been put on record have, in spite of their importance, been passed by. Very briefly, the symptoms may be listed as consisting of the external wound in the precordial region, the general evidences of hemorrhage, the disturbance of the heart function sequent to the trauma and the acute anemia, and the local signs of the filling of the pericardium and, secondarily and in most cases, the pleura. As regards the wound itself, I believe, from examining the hearts which I have punctured and incised, that the endocardial wound is always smaller than the epicardial wound, excepting, I should imagine, in the bullet wound cases. This difference in the size of the wound at its two limits will explain the living of some with apparently large wounds, but from which the amount of bleeding has not been commensurate with the size of the visible wound. It is necessary only to revert to the fact that the different parts of the heart behave somewhat differently when wounded. The thicker wall of the left ventricle offers a greater obstacle to hemorrhage and a better opportunity for suture than any other part. Wounds of the right ventricle bleed more, and are more difficult to suture, and the thin walled auricles are saved from a lethal hemorrhage, when they are wounded, by the comparatively low pressure of the blood in them, while in their loose structure a practical suture is a difficult thing.

Conclusions.—The operations which have been recorded mark only the beginning; the heart is now

CASES OF SUTURES OF WOUNDS OF THE HEART *

Operator and Year	Location of External Wound	Chamber Wounded and Size of Wound	Time of Operation After Injury	Anesthetic	Results and Remarks
1 Farina 1896	Just above the margin of the left sixth rib, near the sternum	R. V., ½ inch, 3 stitches			Death on sixth day, from [illegible] pneumonia
2 Cappelen 1896	Fourth left intercostal space in mid axillary line	L. V., 1 inch	1 hour		Death after several days; [illegible] branch coronary artery [illegible]
3 Rehn 1896	Fourth left intercostal space near sternum	R. V., 3 stitches	Following evening		Recovery; empyema
4 Parrozzani 1897	Seventh left intercostal space in mid-axillary line	L. V., ½ inch	5 hours	None	Recovery
5 Parrozzani	Third left intercostal space	L. V., ⅜ inch	½ hour	None	Death on second day from anemia (?). Interventricular septum had been cut
6 [illegible] 1898	Under left nipple	Apex; cavity not opened, 1 stitch	Several hours		Recovery; empyema
7 Ninni 1898	Fifth left intercostal space	L. V., 3 stitches	Quickly	None	Death on table
8 Parlavecchio 1898	Fifth left intercostal space	L. V., 1½ inch, apex	5 hours	Chloroform	Recovery
9 Giordano 1898	Second left intercostal space	L. A., ½ inch, 4 stitches	½ hour	None	Death on nineteenth day from empyema; abscesses of right lung
10 [illegible] 1899	Fourth left intercostal space midway between margin of sternum and nipple	R. V. ...	12 hours	Yes	Death after twelve hours
11 [illegible]	Fourth left intercostal space	Two wounds; nonpenetrating		None	Death on twenty-second day from empyema, pericarditis
12 [illegible]	Fifth left intercostal space ½ inch internal to nipple	L. V., 3 stitches	At once	None	Death in fifteen minutes
13 [illegible]	At third left cartilage ½ inch from sternum	R. V., 2 wounds, 1 nonpenetrating; 4 stitches		None	Recovery
14 [illegible] 1899	Shot through breast	R. V., catgut suture			Death
15 [illegible] 1899	Fifth intercostal space	L. V.; ½ inch; not certain it penetrated ventricle		None	Recovery.
16 [illegible] 1899	. . . .	R. V., 1½ cm. long			Death
17 Maliszewski 1899	. . . .	. . .			Death.
18 Maliszewski 1899	. . . .	. . . .			Death.
19 [illegible] 1899	Sixth left intercostal space	R. V.; gunshot, 22-caliber	. . .	. . .	Death; necropsy showed perforation of ventricle and the anterior opening only had been sutured.
20 Pagenstecher 1899	Fourth left intercostal space beneath the nipple	L. V., near apex, 2 stitches	16 hours	None	Recovery.
21 [illegible] 1900	Third intercostal space, 4 cm. from edge of sternum	R. V., 2 cm. long, 2 interrupted sutures		.	Death on fifth day from infection of pericardium and pleura
22 [illegible] 1900	Below and internal to left nipple cutting sixth rib	L. V., near apex, 3 stitches	1½ hours		Death in twelve hours
23 Fontan 1900	Six wounds with scissors between third and seventh ribs in cardiac region	L. V., 12 mm. long, continuous catgut sutures, 3 stitches	6 hours	Chloroform	Recovery
24 Nietert 1901	.	R. V., penetrated, 3 silk sutures			Death after thirty-six hours
25 Vaughan 1901	Fifth left costal cartilage divided	L. V.; 2½ cm. long, continuous silk sutures, 7 stitches	½ hour	Ether	Death on table from hemorrhage about completion of operation.
26 Nietert 1901	Left of sternum	L. V., not sure cavity was penetrated; 2 sutures.	. . .		Recovery.
27 [illegible] 1901	Left of sternum	R. A.			Death in four days, sepsis
28 Mignon et Sieur 1901	. . . .	R. V.			Death
29 Fontan 1901		L. V., catgut sutures			Recovered, had empyema
30 [illegible][7] 1901	Left of sternum, near sixth cartilage	R. V., 2 cm.	Following day.	Yes	Death on table, degenerate heart muscle
31 Watten[8] 1901	Fourth right intercostal space .	R. V., 3.5 to 4 cm.	. . .		Recovery, right pleura wounded, pneumothorax
32 Lastaria 1901	. . . .	L. V.	. . . .		Died soon.
33 Lastaria[9] 1902	. . . .	L. V., ant. and post. walls; pistol shot, catgut sut. in each	. . . .		Recovery, no complications
34 Nietert[10] 1902	Left sixth interspace, to right of papillary line	L. V., far back, 2 cm.; penetration uncertain; 2 interrupted silk sutures.	12½ hours		Recovery, purulo-sanguinolent effusion and thoracotomy

destined to be submitted to many manipulations, provided they may be done without stopping its action at once. It is a very unsafe thing to prophesy, but that more will be attempted can easily be inferred, for interference with the mitral orifice has already been suggested, and the immediate neighborhood of the heart has been invaded and a saculated aneurysm of the aorta has been tied off, the success of this well-executed maneuver being prevented only by the failure of the atheromatous vessel walls to heal. Possibly, the next step may be delayed as long as the application to the heart of common surgical methods was delayed after Desault had taught us to open the pericardium. Perhaps it may come soon. It is not impossible that a new surgical technic may have to be created, but it is most probable that the next step will be based on the new application of the very old matters of the suture and drainage.

MEMORANDUM OF EXPERIMENTS.

Case I.—Mongrel Newfoundland dog, ether, thorax opened to left of the sternum by turning up a flap of bone, muscle and skin. Triangularis sterni was carefully incised, but the pleura was opened and both lungs immediately collapsed. Pericardium was quickly opened and heart was massaged, as its action failed, to keep it going until the trachea could be opened and the bellows apparatus attached. Manipulations were not quick enough and the dog died on the table. A dissection showed that there was but one pleural sac for both sides of the chest, and that the lungs surrounded the heart much more completely than they do in man.

Case II.—Mongrel Newfoundland, hypodermic of morphine 0.1; ether. Tube in trachea and connection made with a bellows apparatus, which permitted the use of air alone, or of air and ether vapor. Sternum exposed and then split by a costotome. In doing this the left lung was wounded, but the right was not and its inflation proved sufficient for respiratory purposes. Thorax widely opened, pericardium picked up and opened and then, by seizing the edges of the opening with hæmostats and lifting, the heart was brought up into the opening in the chest wall. The heart's action was strong and regular. Heart wall caught with toothed forceps; systole postponed, and then rapid and tumultuous heart action, tugging forcibly on the forceps. Punctured wound into left ventricle, parallel with the superficial fibers. Spurt of blood, dark in color (because of collapse of one lung), systolic in time. The action of the heart was so rapid that it was impossible to estimate the amount of diastolic hemorrhage. Two interrupted cumolized catgut sutures, passed deeply, but not intended to penetrate the endocardium. Hemorrhage controlled absolutely. Pericardium sponged out and closed by a continuous catgut suture. Chest wall sutured, the sutures drawing together the sides of the split sternum, and dog left with a certain amount of pneumothorax, the right lung being easily inflated, but the left being wholly collapsed and at the back of the chest. Deep and half-deep sutures in the subcutaneous tissues and a subcuticular stitch for the skin. Gauze and collodion over suture line and gauze pads and a body bandage over all. The tube was taken out of the trachea—each cut cartilaginous ring sutured and also the membrane between. The separated muscles put in place, and deep, half deep, and subcuticular sutures as in the chest wound, and then same kind of dressing applied. As soon as the bellows apparatus and the tracheal tube were removed active respiration began. After five minutes it was 17 to the minute and fifteen minutes later it was 16 to the minute. The character of the respiration was good. Twenty-four hours later the dog was in a bad state—he would not stand, nor eat, nor drink. Respiration was deep and labored. Dog found dead on the morning of the second day. Heart only examined. The two sutures were easily seen.

Microscopic Examination of the Wound Area.—Exudate on pericardium is comparatively thin, and consists chiefly of coagulated fibrin, in which are polymorphonuclear leucocytes and a large number of small round cells. The pericardium had lost its typical glistening appearance. It is taking part in the imflammatory process on its surface. Considerable amount of altered blood pigment is found in the pericardial exudate. Sutures surrounded by a mass of leucocytes can be seen in this section and the incision extends direct from the pericardium to the endocardium. It is characterized by extensive extravasations of blood, coagulated fibrin, and platelets in which are numerous polymorphonuclear leucocytes. The heart muscle cells on either side of the incision are undergoing either hyalin degeneration or coagulation necrosis. Karyolysis is marked in these cells. In the intermuscular septa between the different fasiculi of muscle fibers are found extensive accumulations of leucocytes, many of which contain pigment granules derived from the blood. No definite evidence is obtained from the section that the repair is advanced to an extent marked by the new formation of blood vessels. The endocardium is somewhat thickened, and is covered with an exudate composed of fibrin, leucocytes, red blood corpuscles and blood platelets. The wound in the endocardium is not closed.

Case III.—Big short-haired mongrel, hypodermic morphine 0.1; ether. Tube in trachea. Sternum split with a strong knife and lungs not wounded. Bellows at work and thorax opened widely. Pericardium split open and heart lifted to surface as in Case II. Punctured wound as before, heart steadied by toothed forceps grasping fibers. Strong systolic jets of blood. One suture, cumolized catgut, controlled it, though it was not passed deeply. A second suture, more superficial, was put in. The pericardium was cleared of blood and sutured and all the other tissues closed as in Case II. Chromicized catgut, thick and strong, was used for the sternum. As the final stitches which closed the subcutaneous tissues over the sternum were placed and tied the lungs were fully inflated to expel all the air possible from the thorax. The dog came out of the ether quickly and whined and struggled. Pulse 156, respiration 18. Two days later the dog was up and about and ate and drank and was friendly. At the end of the week the wound was open somewhat and the dog was weak and sick. He was found dead on the tenth day.

Postmortem.—Tracheal wound healed throughout and without suppuration. Sternal wound healed in part per primam and in part per secundum, except that from the upper and lower ends were open sinuses leading in, and from them came seropurulent fluid. The lower sinus communicated by a tortuous narrow (2 mm.) path with the pleural cavities. Muscles and cellular tissues of the thoracic wall show intense inflammatory reaction. Both sides of chest cavity full of serosanguineous exudate. with purulent flocculi. Entire pleura covered with a fibrino-purulent exudate and lungs adherent at places by fresh adhesions. Lungs atelectatic, free borders and surfaces shriveled and puckered. Cut surface of lung shows congestion but is otherwise normal. Pericardium adherent to inner surface of sternum, the incision in it opened and cavity communicating directly with the incision. Pericardial cavity contains small quantity purulent exudate and same is on epicardium and pericardium, and an adhesion between these exists along the line of incision in the myocardium. Incision may not have opened ventricular cavity. Diaphragm and liver pushed down by the amount of pleural exudate. No changes in abdominal viscera.

Note.—In the laboratory where this dog was operated upon other dogs had been used for experimental abdominal work, and some bone work had also been done. This dog had had an intestinal suture a month before the heart operation. The intestinal and other abdominal work had been followed by clean aseptic healing. The incisions for the bone filling, which were over the trochanters, had in two instances been torn open by the dogs. The heart operation was done with the utmost care to secure aseptic conditions, and in spite of it a massive infection occurred.

Microscopic Examination of the Wound Area.—The epicardium over the incision in the heart muscle is covered by a thick partially-organized exudate, which consists chiefly of coagulated fibrin with numerous polymorphonuclear leucocytes embedded in the meshwork formed by its filaments. A considerable number of new-formed blood vessels and fibroblasts can be seen making their way from the pericardium into the mass of the exudate. This also contains numerous fat globules. The catgut sutures can be distinctly seen in the myocardium and are surrounded by an intense zone of reaction, the chief part of which consists of polymorphonuclear leucocytes and numerous round cells. Evidence of the formation of a few new blood vessels seen at the periphery of the zone. Specimen not stained for microorganisms, but the tissues at these points had the appearance of being infected and look like early abscess formation. For a considerable distance beneath the epicardium over the whole area covered by the exudate there is a marked degeneration of the heart muscle cells. They stain poorly, the outlines are not clearly marked, the nuclei show bizarre arrangement of the chromatin and occasional instances of karyolysis. No evidence of fibrillation can be seen in the degenerated cells. In the inter-

[illegible]

[illegible]

in the spaces between the dead muscle cells, and are also found along the line of incision and in the exudate on the surface as well as about the stitches.

Case VIII.—Big water spaniel, morphine 0.1, ether. The incision in the sternum, made with a costotome, failed to hold to the middle line and the lung was nipped. In opening the pericardium the coronary artery was cut and bled freely, but was easily ligated. In placing the silk suspension loop the rapid motions of the heart prevented accuracy, and the artery was wounded again, and again ligated. The left ventricle was opened by a punctured wound close to the apex, and then a closed hæmostat was put in and opened so as to make the endocardial side of the wound the larger. A continuous very superficial suture controlled the hemorrhage. About 5 c.c. normal salt solution (NaCl 6, KCl 2.5, Ca Cl 0.5, Aqua 1000), with some carmin in it, was put into the pericardium and the incision sutured. About 500 c.c. of the same salt solution was poured into the pleura to displace any residual air. The punctured point in the lung was ligated and cut off. The usual method of closing the thorax. The dog lived about forty-eight hours, and the autopsy appearances were like those of Case VI. The use of the salt solution made no particular difference in the result.

Case IX.—Big mongrel, morphine 0.1, ether. Tube in trachea. Usual approach to heart. Lung nipped by costotome. Heart punctured with needle—as point entered myocardium a postponed systole, which, when it came, was violent and followed by rapid action, gradually slowing to the usual rhythm. The needle was withdrawn after the postponement. This was done to see if the acts of placing a suture could have been done in successive diastole, and the experiment was repeated, but no diastole long enough for a definite act, like pulling through a suture or tying a knot, occurred. The bleeding from the needle wounds stopped spontaneously and quickly. The right coronary artery was cut and bled by spurts during systole, and was then tied. Transverse incision 1 to 1.5 cm. near apex. Two interrupted stitches stopped all hemorrhage. Two c.c. salt solution with carmin in pericardium just before last suture. Pericardium and chest closed in the usual way. Heart beating rapidly and not very forcibly. Dog died in about forty-eight hours.

Autopsy showed conditions similar to those in Case VI.

Case X.—Mongrel fox terrier, morphine 0.1, ether. Tube in trachea. Heart approached in usual way with no collateral injury. No incision in heart. Usual closure of pericardium and thorax. At this point the heart stopped and the chest was reopened and the heart massaged, exciting only feeble fibrillary arhythmical contractions. Strychnine in the femoral vein and in the heart muscle produced no effect.

Death was ascribed to overdose of ether, as the apparatus was set for the administration of ether with the air.

Case XI.—Small mongrel. Same operation as Case X. Again symptoms of heart failure and some delay in the resumption of active respiration, but 2 mgr. of strychnine stimulated both functions. This dog lived two weeks and then had an open wound over the sternum with the loose ends of the costal cartilages projecting from the surface of the wound. He was in good condition and begged for a dead rabbit which was in the laboratory. He was given morphine 0.1 and ether. Tube in trachea through new incision. An attempt to dissect into the pericardium past the lungs, which were assumed to be adherent to the deep side of the cicatrix, failed, and the pleura was again opened. Pericardium was adherent to the cicatrix, was opened; the line of suture had healed perfectly and the visceral side was smooth. Very little fluid in endocardium. No adhesions to heart. As it was out of the question to again close the thorax the dog was permitted to die.

Case XII.—Small mongrel, morphine 0.1, ether. Tube in trachea. Usual approach to heart. Suspension loops. Punctured wound longitudinal 1 to 1.5 cm. Three moderately deep interrupted sutures. Usual closure of pericardium. A change in the method of closing the thorax was a failure and the dog died in a few hours.

Two Belgian hares and two rabbits were also used because of their having two pleuræ separated by a mediastinum, but we failed to be able to open the pericardium without opening the left and sometimes also the right pleura in this quartet, and there was no time for further trials.

Closing Remarks.—The early death of these dogs was a disappointment, for I had especially desired to see if the cicatrix in the heart muscle would stretch with the lapse of time, or would yield under the strain of rapid and forcible action. As it was, in no instance was death due to the rupture of the wound or to hemorrhage from the failure of a stitch, and in the two dogs which lived long enough to permit a satisfactory observation, the wound in the heart was rapidly healing. The supervention of sepsis and its usually rapidly fatal effect was apparently unavoidable, for all the technic of the operating room, even to having the preparation of the dog and the instruments and the operating table in the charge of a male trained nurse, was practised. As I have said in the body of the paper, the pleura lacks the mechanical arrangements which favor the localization of infection in the peritoneum, and an originally minor infection has opportunity to become a general and extensive one. Drainage of the pericardium and pleura in the dog is not to be thought of, because the pericardium is in the middle of the one pleural sac, and could only be drained through it; and drainage of the pleura would inevitably result in the collapse of both lungs. Therefore, the dogs were permitted to die, and no effort was made to help them out of their septic state.

THE RELATION OF MEDICAL SCIENCE TO COMMERCE.*

By FRANK BILLINGS, M.S., M.D.

CHICAGO.

I have been informed that there is no rule of the association which fixes the subject of this address. I hope I may be pardoned when I depart from the custom which my predecessors have usually followed when they confined the subject of the address to the progress of medicine during the year just past.

We live in a period of the greatest activity of the history of the world. Modern inventions annihilate time and distance. Electricity and steam approximate the most distant parts of the civilized globe. Vast amounts of capital are invested in electrical, steam and other related interests.

Large commercial enterprises are carried on or launched into new fields, which require money, the employment of the brightest intellects and of skilled and common labor.

Competition is great in all the affairs of men. The struggle for supremacy between nations and between men was never so fiercely contended as now. The world is richer than ever before. Great individual fortunes, the result of the efforts of the few years of a single span of life, are seen everywhere. The wage of the laborer in our country is larger than ever

---

*Address in medicine, delivered at the fifty-third annual meeting of the American Medical Association, held at Saratoga Springs, N. Y., June 10-13, 1902.

[illegible] and he has [illegible] the consequences as well as many of the conditions of life.

The [illegible] gravity, with its perplexing, the evil results of a [illegible] life, the [illegible] which it may breed as well as many other conditions which affect the health of individuals while of interest to medicine, do not necessarily go in the consideration of the broader subject of this paper.

The Broader Application of Medical Science.—Medical science is interested in and is of greater importance to the world than ever before in protecting individuals, States and nations from infectious diseases which are rendered more dangerous than formerly because of a denser population, increased facilities of communication between the peoples of the earth, by travel and by national and international interchange of food and other commercial products.

Medical science, too, is closely identified with the vast national interests of the merchant marine and of national and international commerce. Quarantine against the spread of infectious disease is applied wisely or foolishly in direct ratio to our knowledge or ignorance of the cause, the means of transmission and the evolution of disease. So, too, medicine has to do with the knowledge which will enable man to escape from and finally remove the conditions which cause infection and which render a country uninhabitable to civilized man.

Medical science must safeguard man against infection and intoxication from parasitic diseases of animals used for food and from contaminated and adulterated food and drink. Not only from a humanitarian standpoint is medical science related to commercial pursuits, but the sciences related to medicine have done much to preserve animals used for food and to protect agricultural interests of many kinds from disease and destruction.

One may say, I think, that in no other pursuit which engages the serious attention of men are there as many earnest, unselfish and philanthropic workers as there are to-day in the broad field of medicine.

In the various departments of science related to medicine one finds educated, skilled, energetic, earnest workers after truth, willing to sacrifice home, friends, health and life for the advancement of the science which has for its primary object the conservation and prolongation of human life. Pecuniary reward for them is never large and never commensurate with the character of the work.

Furthermore, great and astounding as are the modern commercial inventions, the progress made in medical science during the last twenty years is equally great.

Is modern medicine prepared to meet the demands of modern progress concerning the questions which interest humanity and commerce? Let us answer the question by a brief retrospect of the progress of medicine and by a statement of the present status of medical science.

First Application of Physical Sciences to Medicine.—From the latter part of the eighteenth to the beginning of the last quarter of the nineteenth century the science of medicine developed steadily upon a rational physical basis. Jenner's discovery of the protection of the human race against variola by vaccination with cowpox illuminates with noonday splendor, an era otherwise gloomy with its hypotheses, theories and superstitions concerning disease.

This single brilliant achievement of the end of the eighteenth century was the beginning of the evolution in medical science which made the nineteenth century notable. The application early in the nineteenth century of physics, of physiology, of pathologic anatomy and of chemistry, to the study of disease, developed a more exact knowledge than before existed. [illegible] Auenbrugger that early period was made through the discovery of methods of physical examination which were slowly developed and perfected by Corvisart, Laennec, Piorry, Skoda, Wintrich, Traube, Louis, Cheyne, Stokes, Graves, Corrigan, Flint, Scudamore and others. Pathologic anatomy made wonderful strides under the labors of Virchow, Rokitansky, Arnold, [illegible] and their students. Physiology was developed by the labors of Johannes Muller, Brucke, Helmholtz, Trousseau, Vierordt, Foster, Carpenter, Magendie and their disciples, and the later knowledge embraced in physiologic chemistry was added to the rapidly broadening field of medicine by Hoppe-Seyler, Schwann, Stricker, Prout, Liebig and others.

Bacteriology.—The development of the microscope during the second and third quarters of the past century added a mighty weapon to the armamentarium of the physicist. The microscope was an aid to the investigators of pathologic anatomy, of physiology, of chemic physiology and of other subjects, and it was the one necessary means by which the teeming world of bacteria was made visible. This discovery and the knowledge which has come from a study of these minute and yet often mighty beings has revolutionized medicine.

It was Pasteur's brilliant studies of the infective microbes of air which led to the discovery of the source of contamination of wounds and which made it possible for Lister to evolve a method of protection of wounds from air infection. The aseptic surgery of to-day is but the evolution of Listerism, which had its basis of existence in the discoveries of Pasteur. With the microscope Pasteur rid the world of the superstition of spontaneous generation. He proved the infectiousness of dust-borne air through the microbes it carried. He blazed the way for others in the study of bacteria as agents of putrefaction, fermentation and of pathologic infection in animals.

Bacteriology became an exact science with the discovery of Robert Koch of cultural methods which made differentiation of bacteria possible. The causative relation of bacteria to all infective processes was practically proved by the laws promulgated by Koch. In twenty years the bacterial cause of tuberculosis, typhoid fever, cholera, diphtheria, pneumonia, pyogenic processes, erysipelas, gonorrhœa, epidemic meningitis, epidemic dysentery, the plague, charbon, glanders, tetanus, influenza, and lepra has been proved.

Parasites.—The discovery of the hematozoon of malaria by Laveran, the recognition of the ameba of dysentery by Loesch, of the ray fungi and especially the actinomyces as infective agents in the lower animals and in man and the more exact knowledge of other animal parasites infecting man and animals, which the microscope has made clear, have been as epoch-making in parasitology as the discoveries of Pasteur and Koch in bacteriology.

The recognition of the relation of bacteria, protozoa and animal parasites to infective disease has been the means of a more exact knowledge of the clinical phenomena of disease, of morbid anatomy, of physiology and of physiologic chemistry than would have been possible without it.

Transmission of Infection.—The knowledge of the cause has led to a study of the life-history of infective organisms outside of as well as in the animal body. The mode of propagation, the means of transmission of infective microorganism by fomites and other agents, has become known. The rôle which insects which infest animals play as definitive or intermediate hosts has been studied and proved. The discovery of Manson of the transmission of *Filaria sanguinis hominis* by the mosquito was of vast importance as a suggestion of the mosquito as a definitive host in malaria. The investigations of Manson, Ross, Celli, Grassi, Dionise, Marchiafava, Bignami, Koch, and others have made our knowledge of malaria exact. With the microscope we may now not only recognize malaria and differentiate it from the other infective fevers, but we may also at the same time recognize by an examination of the blood the type of malarial infection and foretell its course. Not only may we recognize the disease definitely and apply the drug treatment more rationally, but the knowledge of the means of its transmission from man to man enables us to apply preventive measures which, as we shall see later, are of the greatest importance from a commercial as well as from a humanitarian point of view. The recognition of the rôle of the mosquito in malaria has been, furthermore, a stimulus to the study of the same insect in relation to other infections.

The brilliant research work of our own Reed and Carroll in 1900 in Cuba, by which they proved that the mosquito of the genus stegomyia is the sole means of the transmission of yellow fever from man, to man is of great importance as a scientific fact. The influence of this discovery upon mankind as a prophylactic against a disease which has killed multitudes and also from a monetary point of view, in reference to commercial pursuits, is not appreciated at this time as it should be.

Hardly less important is the fact that the *Bacillus pestis* may infect fleas, and these, in turn, infect rats, mice, and man. It is important, too, to know that pests like the house fly may be carriers of infective bacteria from refuse filth to our kitchens and tables and contaminate food and thus infect us with typhoid fever, cholera, and, perhaps, other diseases which are propagated by filth.

The study of bacteria in the laboratory and in the blood tissues of infected animals has led to the discovery of the means by which bacteria disturb the animal economy and produce phenomena expressive of disease. The fact that the blood and tissues of infected animals contained a toxin which could also be isolated from pure bacterial cultures in the laboratory and that this toxin when introduced into an animal was capable of exciting the same phenomena of disease as the bacteria themselves, was positive proof that bacteria excite disease phenomena by means of a toxin which they form. The elaboration of antitoxins in the body of the infected animal was also promptly recognized and not only served to explain the self-limitation of many of the infective diseases, but this discovery also helped us to understand the immunity which one attack of some of the bacterial diseases affords.

Protective Inoculation.—Long before bacterial toxins were recognized as the cause of disease phenomena, Pasteur established the principle of protective inoculation with bacteria of lessened virulence, which was brought about by attenuation of the bacteria by a modification of cultural methods and also by serial inoculation of certain lower animals. This he successfully applied to charbon in sheep and cattle and to chicken cholera. In both of these diseases the bacteria were known and the problems of attenuation could be carried on in the laboratory by direct study of the bacteria before inoculation and afterward when they were recovered from the bodies of the animals experimented on.

His final life's work was no less important, in firmly fixing the immunizing influence of attenuated bacterial inoculation in rabies. Here the discovery of the infecting bacterium escaped every known means of recognition by examination of the tissues and blood of the infected animals microscopically and culturally. Apparently, there are pathogenic bacteria which we do not know, because we have not yet recognized the proper culture material for the successful artificial cultivation of them, nor have we discovered the tinctorial reaction which they may possess and, finally, it is not improbable that they may be infinitely smaller than other bacteria and, therefore, more difficult to recognize.

Pasteur recognized the fact that in hydrophobia the brain and other nervous tissue of an infected animal are capable, when inoculated into another animal's brain, of producing the disease. That the infected brain, used for inoculating animals, contained the bacteria, which caused the disease, was proved by the fact that a stage of incubation occurred in the inoculated animal and that a series of animals were successfully inoculated consecutively from the first. Pasteur then successfully attenuated the unknown bacterium of hydrophobia present in the nervous tissues of an inoculated animal by desiccation of the nervous tissue in a sterile apparatus by methods too well known to repeat. Nor is it necessary to occupy time in repeating the well-known methods pursued by Pasteur and his pupils in the use of the graduated doses of attenuated bacteria contained in the nerve tissues in the prophylactic treatment of rabies. To Pasteur, therefore, do we owe the scientific recognition of the principle of protective inoculation.

It is now a well-known fact, however, that inoculation against disease was practised by the Chinese 1000 years ago. They inoculated the healthy with smallpox as a protection against the disease. Variolization was also practised in Europe in the seventeenth and eighteenth centuries. We read that in 1718 Lady Montague caused a son to be inoculated with variola in Italy and that two years later her daughter was inoculated in England. The practice was followed in Ireland long after the successful establishment of vaccine as a protection against variola. Inoculation against syphilis, or syphilization, was also practised in Europe during the nineteenth century.

To Jenner, however, do we owe the first example of the protective inoculation by means of an attenuated virus. This attenuation we now know was established by the accidental inoculation of milch cows with smallpox, producing a modified disease, vaccinia. That vacciniá, produced in man by inoculation direct from the cow, would protect against smallpox was proved when, in 1798, Jenner successfully vaccinated, direct from the cow, the five-year-old lad William Summers.

The thousands of successful vaccinations which have since been performed and the thousands of lives which have been saved by vaccination are proof of its validity and utility. The immunity established by protective inoculation is apparently the same as that induced by an unmodified attack of variola.

Serum Therapy.—When chemistry had revealed the nature of bacterial poisons and experiments established their relation to the phenomena of disease, it was proved that substances were formed in artificial culture media and in the blood and tissues of infected animals which had the power to neutralize the effect of the bacterial poison in other animals infected with the same organism. Further investigation showed that an animal inoculated with the laboratory preparation of antitoxin was protected against the disease.

Furthermore, it was found that the blood serum of an animal inoculated with bacteria in a non-fatal and repeated dose contained an antitoxin. When the blood serum of the infected animal was injected into a healthy animal, the latter was protected against the original disease.

Antitoxin was, therefore, proved to be formed in artificial media of bacterial cultures and in the bodies of infected animals. When the antitoxin thus formed was injected into an animal it had the power to protect it against the particular bacterial infection or, if given subsequent to the infection of the animal, to mitigate the severity of the disease or to entirely check it.

Thus by Koch and his students was serum therapy established as a principle. Upon this principle there has been established and given to the world the antidiphtheritic serum of Behring and of Roux.

A curative or immunizing serum has been developed for Asiatic cholera, tetanus, erysipelas, plague, epidemic dysentery, streptococcus infection and other diseases. While the serum treatment has not proved successful in all the diseases in which it has been used, it has been so successful in some—diphtheria, for instance—as to firmly establish the principle of serum therapy.

Influence of Bacteriology upon Practical Medicine and Surgery.—These practical results in specific prophylactic and curative therapy is but a part, however, of the influence which bacteriology has had upon medicine. The stimulus, given by bacteriology to the study of pathologic anatomy, physiologic chemistry, clinical phenomena and of physical and chemical changes of the fluids and tissues of the body, has resulted in a knowledge so comprehensive that medical science has been revolutionized within the last twenty years. Speculative theories and hypotheses have given place to facts based upon sound principles proved by experiment and clinical observation.

Bacteriology made possible the comprehension of perfect cleanliness and enables the surgeon to invade every part of the body without fear of infection and has saved thousands of lives which twenty-five years ago perished miserably as the result of disease at that time inoperable, or the result of infection from contact with the surgeon. By means of cleanliness and skill, induced by a broader experience, the surgeon has been able to add to our knowledge information of great value, which could have been obtained, probably, in no other way. He has been able to study disease in the living body and show the relation of a disease process to infection. He has thus been able to clear away many of the misconceptions of symptomatology and diagnosis, especially in disease of the abdominal organs.

Bacteriology has stimulated laboratory clinical diagnosis. Bacterial reaction to sera and blood cultural tests are of the greatest aid to diagnosis. Clinical research work has command of an armamentarium consisting of a knowledge of pathologic anatomy, of physiology, of bacteriology, of chemic physiology and of physics, which allows of a precision in diagnosis never before at the command of the physician.

From the foregoing it seems sufficiently demonstrated that to-day medical science possesses a knowledge so exact that we may answer definitely the question of our relation to the commercial affairs of the world. Infectious diseases which affect agricultural interests, like swine plague, rind pest, fowl cholera, glanders, tuberculosis, actinomycosis, trichinosis, and many of the parasitic diseases of plants and of animals have been studied by scientists with most definite results.

Prevention of Infection.—To-day no sane man believes in spontaneous generation. The presence of an infective disease, whether bacterial, protozoan, parasitic, or fungoid, means the recognition of progenitors in the near environment of the infected organism. In practically every one of the diseases of animals above named the scientific investigator has already discovered the nature of the infecting agent, knows its life history, what conditions are most necessary for its propagation and multiplication and what will remove and annihilate so dangerous an enemy.

Our Department of Agriculture, and especially the Department of Animal Industries, has done much to place comparative medicine on a scientific basis. Briefly stated, there is not a fungoid, parasitic, animal parasitic, protozoan or bacterial disease of the lower animals which cannot, with our present knowledge, be stamped out for all time.

Why do the acute epidemic infections attack the swine, fowl and cattle of the agriculturist? Because the causative germ is allowed to live and multiply after a former epidemic or, it is transplanted from place to place by infected animals or by fomites. All of these acute diseases of the lower animals are preventable. One has but to read of the labors and investigations of Pasteur, in relation to charbon, to the silkworm disease, and to fowl cholera to know what indifferent and careless methods may do to prolong and propagate an infection. On the other hand, proper precautions as to the destruction by fire of the infected bodies of animals and plants, the application of cleanliness through the use of abundant pure water, pure food, air and sunlight would extinguish an epidemic.

This may imply the loss of infected property by the individual, the municipality, the State or the national government, but fall the loss where it may, it is often necessary to destroy absolutely the infected organism, that the greater commercial interests as well as the health of the people may be preserved. For example, actinomycosis of cattle, trichinosis of swine, tuberculosis of cattle, may be absolutely controlled and finally obliterated by proper sanitary measures. The expense of such an undertaking would be relatively great, but under the direction of scientists it can be done. Pasteur, with the aid of the government of France, abolished swine plague, charbon, silkworm disease and other conditions harmful to the agricultural interests, with the result that millions of francs were saved to individuals, to corporations and to the government.

The same happy result would occur here and, in addition, the health of our people would be protected against the possible infection with tuberculosis, actinomycosis, trichinosis and intoxication from other infected animal food.

Smallpox.—But what of the epidemic scourges of the earth, smallpox, yellow fever, cholera and the plague? No rational individual can for a moment doubt the protective influence of bovine vaccination against smallpox. Let one but look up the statistics of the mortality of this disease in the antivaccination period and he will become convinced of the utility of protective vaccination. In London the annual mortality from smallpox from 1660 to 1810 per million of the population was 2,040 to 5,020, while with vaccination, not adequate, however, the death rate per million was from

1831 to 1835	830
1838 to 1853	513
1854 to 1871	385
1872 to 1882	262
1883 to 1892 only	73

In Germany where variola had decimated the population in the prevaccination period, thorough vaccination has practically stamped out the disease. Compulsory vaccination, properly enforced, would effectually eradicate the disease and would free commerce of the losses due to quarantine regulations. The question of individual rights, especially under a republican form of government, is debatable when one considers that science has proved the efficacy and utility of protective vaccination against variola; that with modern methods the process is free from the danger of inoculation with any other disease; that vaccinia is practically a harmless disease and, finally, that an individual right may become an evil when the practice of it subjects others to unnecessary risk of health, life and property.

Medical science, therefore, possesses the knowledge to rid the earth of variola. From a humanitarian point of view, this knowledge is priceless. Still, let one but compute the sum saved to the nations of the earth by vaccination, estimating each life saved at $5,000, the usual valuation placed upon human life by statute. Great as would be this sum, it is many times less than that saved to the commercial interests of the world by the control of the disease which even inadequate vaccination has afforded. Think for a moment of the loss to commercial interests by quarantine and other restrictive measures, in the event of an epidemic of variola, without protection from vaccination.

The Plague.—The plague, the Black Death, which was first recognized in Europe in the year 543 as the *Peste Justinienne*,[1] became pandemic in the fourteenth century and 24,000,000 people are said to have died of it. In 1655 London alone lost 70,000 people from the plague. It disappeared from Europe about 1720. It continued, however, in Egypt, Asia and other Eastern countries in small foci, occasionally occurring as severe local epidemics. In 1830 60,000 people died of the pest in Bagdad. During the remainder of the nineteenth century it appeared sporadically in Asia, Turkey, Tripoli, Persia and other Asiatic countries. In 1891 it reappeared, in epidemic form, in middle China. From that date to the present time it spread over China, reaching Canton in 1894, Hong Kong, in epidemic form, in 1896, and in Bombay the same year. It appeared in Oporto, Spain, in 1899; in Glasgow in 1900 and in San Francisco in 1901, not to mention sporadic cases elsewhere in seaports of Europe and Central and South America.

In 1894 Dr. Yersin, Director of the Pasteur Institute at Hong Kong, discovered the *Bacillus pestis*. He elaborated a serum which has since been used with success as a prophylactic and curative agent. Haffkine prepared a protective vaccine which has also proved successful as a protective inoculation. It has been used in hundreds of thousands of cases in India with no harmful results and is said to reduce the susceptibility at least 75 per cent. and the mortality about 90 per cent.[2]

The plague, the Black Death of the fourteenth century, still exists and rages with fearful mortality in communities which have no regard for hygienic surroundings. It is communicated to people through the abraided skin, or by flea bites, through the respiratory tract, apparently by vacteria in dust-laden air, and also through the alimentary tract by contaminated ingesta. Modern hygienic measures, which consist of perfect cleanliness, isolation, the destruction of vermin and the use of Haffkine's vaccine as a prophylactic and Yersin's curative serum, serve to control the disease. There can be no doubt that if sanitary authorities will take proper precautions to recognize the disease, proclaim its presence and then control it by the means which science has discovered, that the terrible scourge may be safely held in check and finally abolished from every civilized community.

The value to commerce of the discoveries of science in relation to the plague cannot be computed. While the knowledge of its cause and prevention is exact, the impossibility of controlling the unsanitary conditions of the countries of the East and even of our own Western world makes it necessary to continue the quarantine regulations which so often restrict commercial ends.

Yellow Fever.—The mortality from yellow fever in the United States during the last one hundred years, 1798-1897, has been about 80,665.[3] This gives an average annual mortality of 807. Several severe epidemics have occurred, and it has prevailed extensively in smaller towns where the mortality records have not been kept. Hence the above figures do not represent the full annual death rate from the disease. Yellow fever has been the scourge of the West Indies, Central and South America, Mexico, and our Gulf States.

Recognized as an infective disease, indefatigable search has been made for the bacterial cause by many earnest workers. Apparently up to the present time the specific infective germ has not been found. Indeed, from a recent paper[4] by Reed and Carroll, it would seem that the bacterium must be infinitesimally small.

Although we do not know the specific bacterium of yellow fever, a most brilliant discovery has been made of the means of transmission of yellow fever by means of the mosquito (*Stegomyia fasciata*) by two of our countrymen,[5] Walter Reed, Surgeon U. S. A., and James Carroll, Contract Surgeon U. S. A. Twenty years ago Finlay associated the transmission of yellow fever with the mosquito, but no proof of this was given until the epoch-making and decisive experiments of Reed and Carroll. Furthermore, these experimenters proved that fomites contaminated with the vomitus and discharges of yellow fever patients do not transmit the disease to man.

In Havana, Cuba, the sanitary authorities of the United States have attempted during the last year or more to test the fact of yellow fever transmission by the mosquito. To this end the city was made clean; the breeding places of mosquitos in and about Havana were destroyed as far as possible, and persons suffering from yellow fever were isolated and protected from the mosquito. Thus the number of mosquitos were much diminished, and care was taken that remaining mosquitos did not become infected by biting yellow-fever patients. As a result yellow fever disappeared from Havana, and for the first time in years no case had occurred up to May 1 of this year. The usual marine quarantine regulations of the United States restricting the non-immune travel from Cuba were postponed. Furthermore, the Congress of the United States will probably modify the quarantine regulations in reference to yellow fever to meet the more hopeful conditions which the researches of Reed and could have [illegible] in relation to the definite transmission and control of the disease.

[5] "Experimental Yellow Fever." Transactions of Association of American Physicians., vol. xvi, 1901.

There can be no doubt of the practical value of this important discovery to mankind. Proper sanitary measures so effective in Havana, the destruction of mosquitoes and their breeding places and proper precautions against the infection of the few unharmed mosquitoes by isolation of every suspected case of yellow fever will eradicate the disease from every civilized country.

Malaria.—Malaria has not borne as important a relation to commercial communication between countries as yellow fever and the plague. Nevertheless it has had an enormous influence upon the health and prosperity of the inhabitants of certain regions where it is endemic and at times epidemic in its prevalence. The principles which prevail to induce malaria in a certain region is the existence of human malaria and of the mosquito of the genus *Anopheles*.

The mosquito is annoying but harmless until she becomes infected with malaria by biting a human being infected with the disease. Such an infected mosquito may inoculate all the people she subsequently stings. In this manner a region ordinarily free from malaria may become infected by the importation of a case of malaria from a distant point. It is also possible that a mosquito infected with malaria could be transported by railroad or ship in the luggage or clothing a considerable distance and then sting and infect individuals in its new environment.

We have many examples of infection of people in localities usually free from malaria, through its introduction by means of imported laborers employed in the construction of railroads, canals, etc. Malaria was rarely found in Chicago until 1891 when the construction of the World's Fair buildings was commenced. Then it was attributed to the excavations and the turning of virgin soil. The construction of the Chicago Drainage Canal began at the same time and continued until 1900. During that period malaria was constantly present in Chicago, and in 1898-9 was augmented by importation of infected soldiers from Cuba and other malarious regions. No one can doubt that malaria was imported in the persons of some of the foreign laborers employed in the above-named enterprises and that the previously innocent anopheles became infected and afterward inoculated many people who suffered from malaria at the period named.

The mortality of malaria in malarious districts with a considerable population is large. Thus Professor Celli[6] says that the mean mortality from malaria in Italy is about 15,000 victims annually, and that about 2,000,000 cases occur in Italy each year. As the mean duration of malaria is generally long, sometimes infecting the individual for years, the loss of labor and of production and the expense entailed in dealing with the disease, amount to several millions of francs. Furthermore, Celli says that, owing to malaria, about 5,000,000 acres of land remain uncultivated with a resulting large economic loss. According to the very accurate calculations of Ricchi, the Adriatic Railway Company with 1,400 kilometers of road and employing 6,416 men, spend on account of malaria alone 1,050,000 francs a year. In the Italian Army in the twenty years from 1877 to 1897 there occurred more than 300,000 cases of malaria. Finally, Celli says malaria annually costs Italy incalculable treasure.

Malaria is so widely disseminated over the world and the opportunity for continued infection of the mosquito so great that it seems almost hopeless to try to eradicate the disease. The principle upon which malaria may be fought has been suggested by science and has proved of value. This consists of the destruction of the mosquito and its breeding places, the prevention of the infection of the remaining mosquitoes by isolation of the malarious individual from the mosquito, and the diminution of malarial material in man by an attempt to cure him with quinine and other anti-malarial remedies.

Experiment has already demonstrated that nonimmune individuals may live safely in the most malarious districts with adequate yet simple protection from the sting of the mosquito infected with malaria. Man thus protected against malaria may now explore, settle in, and develop regions of the earth hitherto inaccessible because of the danger from the deadly tropical malaria.

This address would become too long were one to take up other infectious diseases, although in some of them the science of medicine has made such successful investigations that the knowledge of the cause, means of propagation, and dissemination is exact.

Typhoid Fever.—I cannot close without saying that if in typhoid fever we could employ, unembarrassed by the great cost of the necessary measures, the precautions which science affords to prevent water and food contamination that the disease would be effectually abolished. The great cost of the measures necessary to stamp out typhoid fever would, however, be an economic measure, inasmuch as the immense value to the State, of the conservation of the labor of the thousands sick and the lives saved each year would more than compensate for the treasure spent.

Value of Medical Science Not Recognized.—However much medical science has done for humanity and great as the value of the knowledge of infectious disease is to the commercial interests of the world, scientists have not, especially in our own country, received the recognition and financial aid from the State, from corporations or from wealthy individuals which they deserved.

Medical Science Should Receive Financial Support.—Medical science should receive the moral and financial support of States and municipalities in the employment of the measures which science has proved to be efficacious in modifying, restricting, and abolishing infectious disease. Wealthy corporations and individuals should establish institutes of original research in properly-constructed and equipped hospitals and laboratories. There the many earnest, indefatigable, and conscientious medical investigators could make more perfect the knowledge we already possess of many of the infectious diseases and, unembarrassed by financial needs, could search for the cause, the means of transmission, and the prevention and cure of the diseases of which we know but little.

Funds, too, should be created to support the cost of committees of scientific investigators in regions now dangerous to the white man. By such means the many plagues of the tropics would be investigated and conquered. Regions uninhabitable or dangerous to the Caucasian would become accessible to settlement and commercial intercourse. Civilization, humanity, and commerce would be advanced and multiplied.

It is right, therefore, that medical science should demand of the monied interests of the world the recognition which, though long withheld, is her just due. This she asks, not that individuals may profit in either fame or fortune, but that she may the more readily rid the world of infectious diseases for the sake of humanity.

[6] Malaria According to New Researches, 1900.

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHERS

WM. WOOD & CO., 51 Fifth Avenue.

New York, June 14, 1902.

THE SARATOGA MEETING OF THE AMERICAN MEDICAL ASSOCIATION.

THE meeting of the American Medical Association at Saratoga Springs, to a report of which the greater part of this issue of the MEDICAL RECORD is devoted, will be a memorable one in the history of the Association. It is a very long time, measured by the length of years of the Association, since a meeting has been held in New York State, and for the greater part of the interval the State Medical Society, the parent we may say of the National Association, has been under the ban, and its members have been subjected to much that was unpleasant to bear. But time has done its usual work, the heresy of the State Society, when viewed at close range and with eyes unclouded with prejudice and passion, is seen to be little or not at all different from orthodoxy, and Saratoga will doubtless be remembered as one of the resting places on the road to final harmony. A committee on revision of the code of ethics was appointed, but no action will be taken until next year. It is understood, however, that certain obstacles to the complete union of the medical profession in this State will soon be removed.

The meeting was also the first under the plan of reorganization, the House of Delegates being charged with all the political and non-scientific business coming up for consideration, to the great and manifest improvement in the character of the general sessions. The fact that only the first of the general sessions was held in the morning relieved the pressure on the program of the sections, and gave the members more time for serious discussion. The new plan worked with less friction than had been anticipated, but it was suggested that hereafter the routine business of the House of Delegates be despatched just prior to the first regular session.

The attendance was very much smaller than had been looked for, not more than fifteen hundred members having been registered. Dr. Wyeth, as it was known he would, made a dignified and acceptable presiding officer, and to him is due much of the credit for the success attending this fifty-third meeting of the Association.

THE ETIOLOGY OF DENGUE.

SINCE the article contributed by Professor Graham of Beyrout, Syria, attributing dengue to the bite of infected mosquitos, was published in the MEDICAL RECORD, much interest has been manifested in the matter. The Surgeon General of the Marine Hospital Service has requested the medical men attached to the service situated in tropical countries to investigate closely any cases of dengue which may come under their notice and to communicate the result to headquarters, so that data may be collected, and if considered advisable further close research may be prosecuted.

Writing upon the characteristics and spread of dengue epidemics in Allbutt's System of Medicine, Dr. Patrick Manson says: The most remarkable feature about epidemic dengue is the rapid way in which it spreads through a community and the large portion of individuals affected; so rapid is its diffusion, that it may be described as bursting upon a place, both in suddenness of epidemic rise and in the large number attacked, it is comparable to influenza.

Referring to the nature of dengue the same writer says: "There can be little doubt that dengue belongs to the same class of disease as measles, scarlatina, and the other exanthematous fevers. Analogy distinctly points to this. Certain writers, however, oppose this view, principally on the ground that the epidemic extension of dengue is so rapid and so wide that there can be no time for the operation of infection from person to persons. Such writers invoke some vague telluric or atmospheric influence to explain the rapid extension of the disease in epidemics, and the tendency it exhibits from time to time to become rapidly pandemic. But if we bear in mind the shortness of the incubation period, the almost universal susceptibility of a population unprotected by a recent visitation of the disease, the frequency of mild attacks, which, even during their height, do not incapacitate the subject of them from walking about the streets and thus diffusing the infection far and wide, and the marked tendency it shows to prevail especially in towns and densely populated quarters, one can readily understand that the entire population of a city may be exposed to and acquire the disease within a fortnight of the importation of the first case. Dengue in this respect closely resembles influenza.

As to the nature of the poison or germ of dengue, there are no well established data on which to base a very definite opinion. Bacteria, of course, have been described in connection with this as with every other fever, but the value of the observations is at least doubtful. Probably the germ of dengue resembles those of the other infectious fevers, which, with the exception of that of relapsing fever, are still hypothetical. It is a singular and suggestive circumstance that although some of the exanthematous fevers prevail and spread during the cold season in the tropics, as readily as during the hot, there are others—yellow fever and dengue—which cease at once to extend when the temperature of the atmosphere sinks below a certain point. Analogous and similarly suggestive contrasts in their heat-resisting capacity are supplied by the malarial germ and by the hypothetical germs of beriberi and rheumatism.

These are the views as to the cause of dengue propounded by one of the greatest authorities on tropical diseases, and one who has had many opportunities of observing the idiocyncrasies of the first named malady. There are two points in Dr. Manson's remarks which are particularly worthy of notice. The well-known fact that dengue in its onset and many of its symptoms closely resembling influenza and that dengue and yellow fever disappear with the occurrence of cold weather. The mosquito has been shown to be the principal if not the only means of spreading yellow fever, and the disease ceases with the advent of cold weather because the mosquito is inactive at that time.

If a coincidence, it is a somewhat peculiar one that dengue acts in exactly the same manner. This similarity between the two maladies lends weight to Dr. Graham's theory that a species of mosquito is the intermediary host of dengue and man.

There would seem to be an inherent probability that Dr. Graham has discovered the cause of dengue, although his views will need further confirmation from independent investigation before being regarded as in any way conclusive.

SO-CALLED IDIOPATHIC HÆMATURIA.

The term idiopathic could well be dispensed with in medicine. It is unnecessary, and it may be misleading, if not obstructive. Sifted to the final analysis no disorder can be considered truly primary. There may be an initial cause, but the effect may be multiple and varied. While on the one hand the assumption of knowledge we do not possess is to be deprecated, and on the other hand confession of ignorance is not essential, all obstacles to the attainment of a clearer insight into the ultimate causes of morbid conditions should so far as possible be removed. There are not a few disorders concerning whose nature and etiology we are not as yet fully informed, but this fact constitutes no reason for giving up the quest for this knowledge, and designating them idiopathic. Such a course is likely to obstruct rather than to promote progress. Far better is it to recognize the hiatus in our knowledge, and to devote our energies to bridging the gap.

Cases of hæmaturia of renal origin are on record in medical literature, in which after exposure of the kidney, with or without further operative procedure, the hemorrhage has ceased. In some instances nephrotomy was performed, while in others the kidney was not even opened, being sometimes palpated and sometimes replaced from an abnormal to a normal situation. In many of these cases no lesion was found, although in some slight vascular and inflammatory alterations were present, and it may be that in all some such change would have been discovered if carefully looked for by approved methods, although it would seem that at times nervous influences are possibly operative factors. Similar conditions have also been found in cases in which it became necessary to practise nephrectomy for the control of the hemorrhage.

In a recent communication Dr. Leonard G. Guthrie (*Lancet*, May 3, 1902) reports a condition that he designates "idiopathic," or congenital hereditary, and familial hæmaturia, and he reports a family, in twelve members of which the disorder was present, namely, two sisters and two brothers and five children—four girls and one boy—of one of the sisters, and three children—two boys and one girl—of the other. He describes as characteristic of the disorder its hereditary, familial, and congenital occurrence, its persistence for many years in varying degree, with recurring attacks or paroxysmal exacerbations, and its dissociation from œdema, ascites, and the cardiovascular changes following ordinary nephritis. Except for the presence of blood and occasionally of a few crystals of uric acid or of oxalates, the urine contains no abnormal ingredient. None of the patients was a bleeder. It was thought that calculus, new growth, tuberculosis, nephritis, and congenital syphilis could be excluded. The kidneys were not movable, palpable, or tender, and there was no definite or constant local pain. Three cases of recurrent hæmaturia occurring in one family, all in females, reported by Dr. W. H. W. Attlee (*St. Bartholomew's Hospital Journal*, December, 1901) are believed to be of the same nature. In explanation of the hæmaturia in these cases, it is suggested that there may be some inherent weakness or varicosity of the walls of the renal vessels leading to what has been called renal hemophilia or renal epistaxis, or that the vasomotor system may be at fault (angioneurosis).

THE LOWEST FORMS OF LIFE.

Dr. Gary N. Calkins of Columbia University, according to the New York *Tribune*, during the past two years has been pursuing experiments to determine whether it be possible to prolong life in the lowest animal forms. The paramæcium, or infusorium, regarded as the lowest form of animal organism, was the subject of these investigations. The paramæcia, like other protozoa, multiply by fission, but with this species of infusoria the division is crosswise. This fission occurs, at least once a day, so long as the organism and vitality is maintained, but after a time reproduction ceases, unless two specimens fuse temporarily. Then the same process of splitting continues. It is said that Dr. Calkins has discovered a method of extending the life period of these protozoa by artificial means. With its natural sustenance a paramæcia averages about 170 generations. Dr. Calkins has lengthened this term by no less than 330 generations. The first agent employed was beef broth, which was successful in increasing the capacity to multiply by a very considerable extent. Dr. Calkins then concluded that it was the mineral salts of the meat that exerted the revivifying effect upon the vitality of the infusoria—in fact, that the action was a chemical stimulus. These suspicions were substantiated by experiment with weak solutions of potassium phosphate. One of the most interesting results of the foregoing researches has been the demonstration that, while the chemical treatment renders more active multiplication by fission, it tends to diminish the vitality of the progeny of those who have received their stimulus from mineral salts. Dr. Calkin's investigations would seem to show that, by chemical stimulus, the life of the protozoa may be extended almost indefinitely. The processes of life are now declared by certain scientific men to be ruled by chemical action, and experiments of the nature undertaken by Dr. Calkin, Professor Loeb, and others, may serve to make clear some of the obscure points of metabolism.

Dr. A. N. Richards, assistant in the department of physiological chemistry at the College of Physicians and Surgeons, has been appointed to a research fellowship in the Rockefeller Institute for his recent investigations in the field of physiological chemistry.

News of the Week.

The Surgeon-General of the Army.—The President has sent to the Senate for confirmation the nomination of Colonel William H. Forwood, Assistant Surgeon-General, U. S. A., to be Surgeon-General for a period of four years, with rank of Brigadier-General, *vice* Major-General George M. Sternberg, retired.

The Congress on Tuberculosis.—The third annual session of the American Congress of Tuberculosis and the Medico-Legal Society opened June 2 at the Hotel Majestic in this city. Besides delegates from many States and Territories, there were present representatives of Canada, Mexico, and Central and South American Republics. The United States Government was represented by officers of the army, navy, and Marine Hospital service. The honorary president, Dr. A. N. Bell of Brooklyn, first defined the purpose of the congress, which is to discuss measures of protection and resistance to tuberculosis. Then Dr. Henry D. Holton of Vermont read the presidential address. He said there are more than half a million tuberculosis patients in this country, and of this number at least 400,000 are doomed to die of the disease. Intemperance, insufficient clothing, dampness, filth, overcrowding, and improper food are the chief direct causes. Among the preventives he placed as the most important the education of the masses in better methods of living.

The first discussion was on "Preventive Legislation," and at its close a resolution was adopted declaring it to be the "duty of every government, municipality, and individual citizen to adopt organized methods for lessening the spread of a disease which is causing, directly or indirectly, probably one-fifth of the total deaths in almost every country in the world. The majority favored the establishment of county sanatoriums for the treatment of subjects in the early stages of the disease and hospitals for the segregation of incurables. Dr. Wm. Oldright of Toronto drew attention to the prominent position of female school teachers in the tuberculosis mortality lists of this country and Canada; and he proposed a resolution, which was adopted, drawing attention to the fact that the average amount of air space in schools is less than half that recommended by sanitarians, and urging upon the authorities the necessity of providing larger accommodations and better ventilation in school buildings.

The discussion of bacteriology and pathology was opened by Dr. L. L. Kinyoun of the Marine Hospital service, who expressed his belief in the identity of human and bovine tuberculosis. He did not believe in the curative power of any of the anti-tuberculosis serums, and said that disinfection was the most important factor in the prevention of the disease. Dr. H. E. Lewis and others contended that the chief bulwark against the disease was the improvement in the power of individual resistance.

The dinner was held on the evening of the second day of the session, and at this a silver loving cup was presented to Mr. Clark Bell, the secretary and treasurer of the congress and of the Medico-Legal Society. Dr. T. N. McIntosh of Thomasville, Ga., made the presentation.

At the closing session the discussion was on the "Veterinary Aspects of Tuberculosis," the opening paper being by Dr. Adami of Montreal. Before adjournment, the congress adopted a series of resolutions urging the health authorities to disseminate correct information as to the manner in which this disease is produced and the means to be employed in its prevention," calling upon the national, State and municipal governments to enact rational methods for the prevention of tuberculosis, and recommending the establishment of institutions for the care of indigent consumptives. It was further resolved that there should be State and municipal supervision of public conveyances to suppress spitting, and that appropriations should be requested for the "publication and distribution of literature as a means of education in the prevention of the spread of tuberculosis." Finally, "that all cases of tuberculosis should be reported by the attending physician to the health boards for the purpose of the disinfecting of houses occupied by consumptives."

The election of officers resulted as follows: *Honorary President*, Dr. H. D. Holton of Vermont; *President*, Dr. Daniel Lewis of New York; *First Vice-President*, Dr. J. A. Eagan of Illinois; *Second Vice-President*, Dr. Frank Paschal of Texas; *Third Vice-President*, Dr. E. J. Barrick, of Toronto; *Fourth Vice-President*, Dr. J. A. Watson of New Hampshire; *Fifth Vice-President*, Dr. Romola of Guatemala; *Secretary*, Dr. George Braun of Georgia; *Treasurer*, Dr. P. H. Bryce of Toronto.

Vaccination Charged as Assault.—The principal of a public school in Brooklyn and an inspector of the Health Department were brought to court recently on the complaint of the father of one of the pupils, charging them with assault in the third degree. The complainant alleged that his daughter, six years old, was forcibly vaccinated by the physician at the direction of the principal. The parents had been informed that all the children in the school would be vaccinated unless they could produce a physician's certificate that this operation had already been done. The father of the child in question did not produce the necessary certificate, although he claimed that he had one, and so the child was told she must be vaccinated, and to this, the accused physician and principal assert, she gave her consent. The case has not yet been tried.

Ophthalmia a Notifiable Disease.—The Board of Health has declared ophthalmia, both acute and chronic, to be a contagious disease. Under this decision, physicians will be required to report promptly to the Department of Health all cases of the disease that they may find. The Board of Education will also be asked to lend its aid toward stamping the disease out of the public schools, where it is now prevalent.

Medical Appointments at Columbia.—At a recent meeting of the trustees of Columbia University, the resignation of Dr. Abraham Jacobi from the chair of pediatrics was accepted. He was appointed professor emeritus, and Dr. L. Emmet Holt was designated to succeed him. Other faculty appointments in the College of Physicians and Surgeons were: Dr. L. E. Lefetra to be instructor in the diseases of children; Dr. A. E. Schmitt to be assistant in operative surgery; Dr. Joseph H. Bair to be assistant in anthropology; Dr. R. E. Buffington to be assistant in normal histology; Dr. Russell B. Opitz to be demonstrator in physiology.

The American Roentgen Ray Society will hold its next meeting in Chicago on December 10 and 11 of the current year, under the presidency of Dr. G. P. Girdwood of Montreal. The secretary of the society is Dr. James B. Bullitt, 205 West Broadway, Louisville, Ky., and the chairman of the committee of arrangements, Dr. Ralph R. Campbell, 414 Marquet Building, Chicago.

The Board of Health in Brooklyn.—In order to lose no time in the investigation of cases of diphtheria and smallpox which are reported at night, Dr. Raymond, Sanitary Superintendent in the Borough of Brooklyn, has decided to keep the Health office upon all bottles sold to keep an inspector busy looking at all times. The Health Department has established a culture oven in which diphtheria cultures will be tested. Cultures from the infected persons can now be sent direct to the Brooklyn office, instead of being left at drug stores, collected in the morning by inspectors, sent to the bacteriological laboratory in Manhattan, and returned to Brooklyn.

The Late Dr. Arthur T. Muzzy.—The following was read at the meeting of the Society of the Alumni of the City (Charity) Hospital held on Wednesday, May 21, 1902: "Dr. Arthur T. Muzzy, who was at the time of his death the President of the Society of the Alumni of the City (Charity) Hospital, deserves our thoughts as we are gathered at this the one hundredth meeting of our organization. Previous to his election to the presidency, Dr. Muzzy had served the society with a conscientious devotion to its welfare that was not always recognized, because, with an unfailing zeal, there was so much modesty that we did not know of his efforts. He never mentioned his own part, but praised others. Such a man is rare, especially in a great city given over to commercial pursuits with personal advancement always prominent. Our late President was a man of broad and scientific training. He expressed his opinions in a simple, direct manner, that showed him to be a well-read and experienced clinician. Not only was he a valued consultant, but he was a painstaking practitioner in the specialty to which he gave so much of his professional life. Expert in his operations, he had a knowledge of pathological processes that enabled him to carry to a successful issue many a doubtful case. He wrote little for publication, but all that he put in print will bear comparison with similar articles. Dr. Muzzy's personality was gracious and winning. Honest and true, he never expected others to be anything else than honorable. In his death this society has lost more than its presiding officer; it has lost its association with a man who not only was a scientific physician, but also a friend, one who was an upright Christian gentleman. We can bear him no better testimony than to acknowledge the benefits that accrue to all who realize the value of a high personal standing among the members of our profession." Signed: J. B. Bissell, William L. Stowell, Walter Lester Carr, Committee.

The Medical Society of the State of West Virginia held its thirty-fifth annual session in Progress Hall, at Parkersburg, on Wednesday, May 21, and the two following days. The following papers were read and discussed: "The Hygienic Treatment of Tuberculosis," by Dr. C. F. Ulrich, Wheeling; "Pulmonary Tuberculosis, Its Treatment in the Remote and Recent Past," by Dr. J. L. Dickey, Wheeling; "Pulmonary Tuberculosis, Its Treatment at Present," by Dr. Wm. A. Caldwell, Morgantown; "An Analysis of 150 Operations for the Radical Cure of Hernia," by Dr. Frank Martin, Baltimore, Md.; "Movable Kidney," by Dr. R. J. Reed, Wheeling; "Some Features of Medical and Surgical Study in London and Berlin," by Dr. A. S. Grimm, St. Marys; "Intestinal Anastomosis," by Dr. J. R. Cook, Fairmont; "Tonsilitis," by Dr. V. T. Churchman, Charleston; "Tubercular Peritonitis," by Dr. J. Schwinn, Wheeling; "Some of the Effects of Typhoid Fever on the Nervous System," by Dr. C. C. Hersman, Pittsburg, Pa.; "Spinal Anæsthesia with Report of Cases," by Dr. O. O. Cooper, Hinton; "On the Management of Rectal Diseases," by Dr. Wm. M. Beach, Pittsburg, Pa.; "Quarantine," by Dr. T. L. Barber, Charleston; and "The History of a Bullet in the Apex of a Man's Heart for Thirty-five Years," by Dr. E. T. W. Hall, Weston. President Anderson's address was an interesting résumé of the achievements in medicine and surgery in the past century in general and in the past year in particular. In addition it dealt in a highly practical manner with the problem of reorganization. In accordance with his recommendations, the Society has been reorganized, assuming the name of the "West Virginia State Medical Association." Dr. H. B. Stout of Parkersburg was elected President, Dr. William W. Golden of Elkins was reelected Secretary, and Dr. V. T. Churchman of Charleston was elected Treasurer. The next meeting will take place at Charleston in May, 1903.

The Famine in Russia.—It is reported that the situation of the famine-stricken peasants in many of the provinces of Russia continue to grow worse. Great numbers of the people who have not actually died of starvation have succumbed to scurvy. In 241 villages in one district 6,815 cases of this disease were recorded in one month, an increase of over 4,000 cases over the figures for the preceding month.

Army Nurses.—The War Department has issued an order prescribing the duties and status of the Army Nurse Corps. The pay and allowances of a nurse on active service is to be $40 a month when on duty in the United States and abroad. Chief nurses get $5 extra, but when they have five or more nurses under them they get $10 extra, and $25 extra when they have ten or more subordinates. The uniform of the Army Nurse Corps will consist of a waist and skirt of suitable white material, adjustable white cuffs, Bishop collar, white apron and cap. The badge of the corps is the cross of the Medical Department, in green enamel, with gilt edge, pinned on the left side of the collar of the uniform or on a corresponding part of her dress when she is not in uniform. After appointment nurses serve for at least three months in the United States, during which period they will receive special instruction in army nursing. The appointment of an army nurse will be for three years, two of which will usually be passed in service in the island possessions of the United States.

Obituary Notes.—Col. DALLAS BACHE, surgeon United States Army, retired, is dead at his home in San Diego, Cal. He entered the army as assistant surgeon in 1861, and served in the field during the entire Civil War. After the war he was stationed for a time in San Francisco, and for a number of years was the chief surgeon of the Department of the Platte, with headquarters at Omaha. Later he was at Washington as assistant surgeon general. He remained on duty there until his health failed, and then went to San Diego.

Dr. BENJAMIN A. CHURCH of Oneonta, N. Y., died very suddenly on June 6. He was born in 1865 at Coventry, and was graduated with honors from the Medical Department of the University of New York in 1878, being later connected with the university. He was a prominent member of the Medical Association of the State of New York.

Dr. WILLIAM ARMISTEAD NELSON died in this city on June 5. He was a descendant of the Nelson family of Virginia, prominent in Revolutionary times, and was born at Fredericksburg in 1817. He studied medicine at the University of Pennsylvania, where he took his degree in 1839. He was soon appointed as assistant surgeon in the United States Navy, and accompanied Commodore Perry on his expedition to Japan. In 1854 he was appointed surgeon. He resigned shortly before the Civil War, and on the outbreak of that conflict joined the Confederate Army as surgeon, serving at Yorktown, Richmond, and in Louisiana. After the war he moved to Missouri, where he practised medicine for many years.

Progress of Medical Science.

Journal of the American Medical Association, June 7, 1902.

A Brief Summary of the Clinical, Pathological and Bacteriological Features of Cutaneous Blastomycosis (Blastomycetic Dermatitis, of Gilchrist).—F. H. Montgomery reports the results of joint observations made by J. Nevins Hyde and himself. Their views are summarized in the following propositions: Under the term "cutaneous blastomycosis" (or "blastomycetic dermatitis") have been collected a series of cases presenting a clinical picture differing from that of all other recognized dermatoses. The disorder has also a characteristic histopathology. The organisms in tissue have been in every case of the budding variety. In cultures they have appeared as budding or as mycelium-forming fungi, of which there are probably several varieties. While the disorder occurs independently of all other diseases, it has been followed in at least one instance by tuberculosis. Secondary pus infection of the lesions is common, and there is no reason apparent why secondary infection with tubercle-bacilli or other bacteria should not occur. It is possible also that the fungous disease is capable of implantation upon the lesions of other disorders. Practically all cases of the disease in which potassium iodid has been employed in large doses have improved decidedly under its administration, but only a small percentage of patients recovered entirely under that treatment alone. Cutaneous blastomycosis and protozoic dermatitis are undoubtedly closely related disorders, if not varieties of the same process. It is possible, however, that the blastomycetes and other fungi are capable of producing in man a series of disorders of different clinical types.

Notes on Aneurysm.—William Osler contributes several clinical histories illustrating certain points. Case 1 was that of a bullet wound of the right subclavian artery and vein with the formation of an arteriovenous aneurysm. Operation was not advised and the patient was in good health two years later. Cases 2 and 3 furnished illustrations of the "humming-top" murmur in thoracic aneurysm and are thus summarized: Case 2 was that of a young man. Syphilis three years before admission. Cough. Shortness of breath. Aneurysmal tumor to right of sternum. Loud continuous murmur with systolic intensification. Post mortem. Communication of a large branch of the right pulmonary artery with the aneurysmal sac. Case 3 was that of a man who had had syphilis two years before observation. Cyanosis. Shortness of breath. Great congestion of the veins of the upper half of the body and of the arms. Gradual development of compensatory circulation in the mammary and epigastric veins. Over the manubrium and aortic regions a continuous murmur with marked systolic intensification, limited to the area about the aortic cartilage and the middle of the manubrium. Death. No autopsy. Case 4 illustrated the value of the fluoroscope in the diagnosis of obscure cases of thoracic aneurysm. The main features were cough and dyspnœa for six months, much emaciation, flatness to the left of the sternum, leading to a diagnosis of mediastinal sarcoma. Examination with fluoroscope showed a characteristic pulsating tumor, and subsequently there was slight pulsation of the thoracic wall. The sac was wired. Death resulted from hæmoptysis. Osler insists upon the value of a careful examination of the barrel chest in cases of suspected aneurysm.

Medical News, June 7, 1902.

A New Method of Treating the Morphine and Alcohol Habits.—H. A. Hare reports the treatment suggested by Lott, of using massive doses of hyoscine in the treatment of various forms of drug habit. The patients can take as much as one-quarter grain each day hypodermically, with no evil effects on any vital function. They suffer very slightly, if at all, from the immediate withdrawal of the morphine, and the desire for the drug largely or entirely disappears after a few days. The writer then reports several cases in which he has used this treatment with gratifying success. One of the patients was not only a morphine but also an alcohol-habitué. She is at present progressing toward what seems to promise a permanent cure. Hare thinks the results obtained by this method of treatment have been remarkable and justify its further use.

The Comparative Physiology of Faith Cures.—Pearce Bailey gives the following characteristics of the two selves which are present in every man: The higher is attentive, reasons, analyzes, criticizes, acts with purpose rather than from impulse; in it memory is active and accurate. The secondary self is antithetical to this; in it attention is unstable; the ideas leading to conclusions are disconnected; the conclusions which lead to action are arrived at by impulse rather than by reason; deliberation is well in the background, credulity well in the fore. The subconscious self is devoid of originality, its reaction to external stimulating essentially automatic and traveling the paths of least resistance. According to which self is in control, the character of the individual is proclaimed. From the physiological standpoint, what are commonly regarded as the instincts of animals are not instincts in the sense that they result from memory or volition on the part of the animal, but they are a series of reflexes which affect the animal's whole organism, and which are performed independently of volition or consciousness. So what the psychologist calls subconscious action, the biologist calls atropism; both terms indicate automatism unguided by intellectual control. No man is so perfected as to be free from it, but when it becomes the dominant expression of nervous activity, when a civilized human being in his automatism remains the puppet of inane suggestion, deaf to the higher callings of reason and reflection, he represents the mental state which we believe man held when the difference between him and the lower animals was narrow. He shows that in the process of brain elaboration he has been passed over. Crazes of all kinds are self-limited and self-destructive. Although they come and for a time flourish, they will as surely pass away.

The Advantages of Early Surgical Intervention in Border-Land Cases.—Roswell Park presents a most interesting paper on this subject. One of the greatest disadvantages with which the surgeon has to contend is the late hour at which many surgical cases are referred to him. Park reviews various lesions of various organs and the advantages of surgical treatment for the same. A well-founded suspicion of cancer justifies an operation for its determination and relief. As to epilepsy, the author states that not once in five times is he consulted early enough to give a fair prospect of accomplishing what might have been done earlier. Lumbar puncture has not yet come into sufficient favor. In regard to the surgical treatment of nerve-trunks, it is often sought so late, and after the patient's strength and powers of endurance are so lessened by suffering and drugs, that recuperative power is at a low ebb. As to disorders of the ductless glands, even in exophthalmic goiter, when drugs fail, either early extirpation of the thyroid or Jonnesco's operation of excision of the cervical sympathetic, has in many severe cases given better and quicker results than any other means. Asthma is often dependent upon intranasal conditions or lesions of adjoining parts. The primary treatment of cervical tuberculosis must usually begin in the oro-, or nasopharynx. As to empyema, pus allowed to remain will do more harm than can a surgeon's knife if judiciously used. In cases of pericarditis it should be emphasized that when the pericardium is distended with serous fluid it should be aspirated, and when this fluid is pus, thoracotomy should be done and the sac opened and drained by gauze or tubing. Abscess of the liver should be explored early with the aspirating needle. Success in the treatment of tumors of the liver is in proportion to the promptness with which it is instituted. The writer believes that not only a suspicion of cholelithiasis justifies an exploration of the gall-bladder, but also when a patient suffers from dyspeptic symptoms with pain and tenderness in the region of the gall-bladder, and especially with any evidence of biliary pigmentation, this region should be explored whether or not the gall-bladder can be felt from the outside. The more acute the lesion of the pancreas, the more is immediate surgical intervention indicated. In lesions of the kidneys, decapsulation is often performed. This not only relieves the tension on the organ, but also produces adhesions between the decorticated surface and the surrounding tissues, so that by the new-formed vessels new circulation is established and the function of the organ is renewed—even epithelium is regenerated. The three non-malignant diseases of the stomach, ulcer, benign obstruction, and dilatation, are all amenable to surgical intervention. As to cancer of the stomach, the writer believes that every case of progressive stomach disturbance should be operated upon or at least explored, when to the stomach symptoms themselves are added any two of the following: (1) Rapid emaciation; (2) Achlorhydria; (3) reduced proteid digestion; (4) Lactic acid; (5) Oppler-Boas bacilli; (6) Suspicion of tumor. As to the lesions of the bowels, both malignant and benign, surgical interference is often the method par excellence. Finally, the delay in surgical treatment is often due to the dread of the knife by the patient. The laity need to be educated to the poin of early consent where surgical treatment is indicated

American Medicine, June 7, 1902.

Dermatitis Medicamentosa.—J. B. Shelmire believes it to be of the greatest importance in making the diagnosis of a case strange to trace its possible cause, the fact that there are many drugs which, taken internally, cause eruptions on the body. He reports the case of a man, aged fifty years, who suffered from an unusually persistent and severe erythema, apparently produced by the ingestion of mercury. The first appearance was after the use of a mercurial ointment which he used to rid himself of crab lice. Severe dermatitis followed. The other attacks followed the internal use of calomel. One time the patient had taken it in ignorance of its nature, and learned from the physician after the appearance of the eruption what he had been given. The eruption was fiery red, smooth and shining, an erysipelatous in appearance. There was intense burning with slight itching. The skin also felt very stiff.

A Case of Meningomyelitis Occurring During Convalescence from Typhoid Fever.—Theodore Diller reports this case. The patient was a girl of sixteen and one-half years, who had previously been in good health, till she was stricken with an attack of typhoid fever. This was about May 20. A month after the onset a large bedsore developed over the sacrum and several weeks later several smaller ones appeared in the same locality. About July 25 the fever left her and by October 1 the bedsores were all healed. On August 28 pain in the legs developed and extended along the entire spine. Three days later the leg pains were extremely severe, the thighs were flexed upon the abdomen and the legs upon the thighs. Both legs, the bladder, and bowels were completely paralyzed. The skin of the lower limbs was hyperæsthetic. This condition of absolute paralysis that developed in three days lasted for two months, since which time the motor power has been slowly returning. Treatment consisted in very careful nursing, gentle turning from one side of the bed to the other, use of air cushions, hot and cold applications, sedatives, gentle sponging, and, for some time, of the daily administration of two grams of potassium iodid. The evidence indicates that the inflammatory process confined itself pretty closely to the lower cord region, its upper boundary being about the eleventh thoracic segment. To the symptoms already enumerated must be added the presence of exaggerated knee-jerks.

New York Medical Journal, May 31, 1902.

Conservatism in Abdominal and Pelvic Surgery.—E. Ricketts call attention to the growth of abdominal surgery and to the fact that it is often overdone by younger men. He believes that the polyclinic six-weeks' courses in abdominal and pelvic surgery, the so-called "touch-courses," are not without responsibility in this direction. The opportunities for pre-operative and post-operative responsibility, as to history, duration, and those symptoms that lead up to and show when best to operate, are not equal to the importance of the occasion. Technique, with much stress laid on how to be chemical high executioner of the innumerable little beasts, is too seriously considered. The importance of the shortest possible and intelligent anæsthesias, the meeting of any or all emergencies promptly, are often of the greatest consideration. After a six or eight weeks' course too many men return home thoroughly imbued with the idea that the doing of this work is of the easiest, and so they launch into the abdomen and pelvis. Often they succeed in hysterectomies and in removing a simple ovarian cyst, but in conservatism in the surgery of the uterus and ovaries, they fail in the majority of cases. They are too slow, tedious, and uncertain operators, and inoperative ability in diagnosticating between a healthy ovary and one that demands resection after the abdomen has once been opened, they are very often rank failures. No man ought to operate on the rectum one day and do an abdominal section the next.

Colon Bacillus Infection.—J. H. Burch has seen a series of cases which he is inclined to regard as due to a mixed infection of typhoid and colon bacilli. The duration of the cases is from seven to ten days. The attack is usually ushered in by a period of malaise that continues several days, the patient becoming progressively worse, until at last he is confined to his bed. The seizure is accompanied by a gradually rising temperature that reaches its limit at the end of the third or fourth day, from which time it remains at about 102° F. in the morning and from 103° to 104° F. in the afternoon. There is almost always a certain amount of gastrointestinal disturbance, sometimes diarrhœa, and less frequently constipation. The abdomen is at times distended, and nearly every case is accompanied by abdominal gurgling. The tongue is dry and often charged with a foul coating. There is sometimes a mild delirium and almost always more or less headache. In fact the whole clinical picture is that of typhoid fever. In every case seen, there has been diminished leucocytosis. The urine in many cases contains traces of albumin and sometimes a few granular casts. The reaction is always acid; it is often turbid and swarms with profuse motile organisms resembling the typhoid bacillus. Indican is present in every case, and the Ehrlich diazo-reaction has been as a rule well marked. The Widal-Johnston reaction has been absent in every case throughout its entire duration, but by employing a broth culture of the bacillus found in the urine, following the technique of the Widal-Johnston reaction, agglutination was manifested in every case.

The Lancet, May 31, 1902.

A Case of Arthritis Accompanying Ophthalmia Neonatorum.—The case is reported by C. O. Hawthorne, who calls attention to the fact previously noted by Dakin, namely, that there are two varieties of arthritis associated with ophthalmia neonatorum: (1) A very acute form, with features suggesting a tendency to suppuration, and (2) a milder form accompanied by a great deal of effusion and pain on movement, but with little or no surface redness. The patient was seen by the author at the sixth week of life. At the second week, the right shoulder joint had become swollen, and also the right wrist. These swellings had subsided in the course of a fortnight, without any very active treatment. At the sixth week, while the joints first attacked were quite normal, the left elbow-joint was much enlarged, and the swelling extended down the radial side of the forearm for a considerable distance, giving here a sensation of deep fluctuation, as though the sheaths of the muscles were involved. The skin was not reddened, and though the child objected to manipulation of the joint, he appeared otherwise to be free from pain, and his general nutrition was entirely satisfactory. It was decided to fix the limb and to continue the local treatment of the ophthalmia, and under these measures the patient made a rapid recovery, so that in from two to three weeks the elbow-joint and forearm had regained in every respect their normal characters.

Radical Cure of Inguinal Hernia.—J. O'Conner counsels the following procedure. A four-inch incision is made over the line of the inguinal canal, the sac is isolated from the cord, it is opened, and its interior is carefully inspected, and it is palpated well into the abdominal cavity. Next, an assistant draws the sac forcibly downward, and the operator, while retaining his left index finger within the sac near to the internal ring, in order to prevent intestine or omentum getting caught, transfixes and ligates with catgut, and cut away the distal portion. Before complete separation takes place a pressure forceps is applied to its proximal end, in order that a final inspection may be made before it is allowed to fly back into the abdomen, for a chase after a bleeding point in a retreating stump is not pleasant. The conjoined tendon and Gimbernat's ligament are next thoroughly differentiated from the surrounding parts, and with the left index finger introduced into the canal to act as a guide and protector of important relations four strong fishing-gut sutures are inserted by a curved hernia needle about half an inch apart, from within outward through Gimbernat's ligament and the external oblique, the ends being retained outside the aponeurosis. The free ends are threaded in rotation on a hernia needle with an opposite curve, and are carried from within outward well into and through the substance of the conjoined tendon, these ends being similarly retained outside the sheath of the tendon. A straight aneurysm needle is next made to enter the suture hole in the tendon, passed across, and made to emerge through the corresponding suture hole in the external oblique. The end of this portion of suture is attached and drawn across and out through the aperture of entry of the needle; thus, the two ends emerge from the same hole in the sheath of the tendon, and form a circular submuscular suture. When the four are thus applied—and this does not take a quarter of the time to insert that it does to describe—the assistant draws the cord downward, and the sutures are tied with sufficient force to draw the tendon backward in front of the vas to Gimbernat's ligament, care being taken in the adjustment of the lower sutures not unduly to compress the vessels of the cord. The ends of the stitches are then snipped off, when the knots retreat into the substance of the conjoined tendon, and are sealed over by a catgut suture through each aperture. The operation, which occupies usually from ten to fifteen minutes, is concluded by uniting the skin wound with a continuous blanket suture.

Society Reports.

AMERICAN MEDICAL ASSOCIATION,

Fifty-third Annual Session, Held at Saratoga Springs, N. Y., June 10, 11, 12, and 13, 1902.

GENERAL SESSION.

First Day—Tuesday, June 10.

The meeting was called to order in Convention Hall, Saratoga Springs, at 11 A.M. by the president, Dr. John A. Wyeth of New York, and the session was opened with prayer by the Rev. T. F. Chambers.

Presentation of Flag.—Dr. H. L. E. Johnson of Washington, D. C., presented to the association a flag, and the board of trustees adopted it as the flag of the association. The letters "A. M. A." appear in white upon a dark blue ground.

Addresses of Welcome.—Hon. S. F. Nixon, Speaker of the New York State Assembly, delivered an address of welcome on behalf of New York State. In contrasting the position of the representatives with that of physicians, he humorously remarked that physicians never made any mistakes in diagnosis, but if the representatives of the people failed to correctly diagnose the will of their constituents they were retired to the "convalescent ward," and from this ward many of them never returned to the Legislature. Continuing, the speaker pointed out medical organization as the means by which medical education was at the present day maintained at a standard so much higher than formerly. New York State had been most persistent and earnest in its effort to maintain this high ideal. This was a just cause of pride, but it would seem that similarity of conditions throughout the various States would admit of a practically uniform standard for the whole country. This suggestion was received with hearty applause.

Senator Edgar T. Brackett of Saratoga Springs welcomed the association to that place. He expressed wonder that the preceding speaker, "a successful wholesale dealer in granite and marble," should have been selected to welcome the association to the State, and he was inclined to think that the only reason he himself had been selected to welcome the association to Saratoga was that he might be buncoed by the osteopathic bill. Touching upon the advances made in medicine, the speaker said that it was a far cry from Hippocrates, the father of medicine to the time of Valentine Mott, and a comparatively short interval from that time to the year 1902, yet in the latter period more advance had been made in medicine than in the two thousand two hundred and fifty odd years embraced in the period first mentioned. It was joy, indeed, to live in the age that saw Lister and Koch and Pasteur and the later work of our own great Marion Sims. The future historian would put beside the name of Harvey "well done;" in recounting the doings of Jenner she would add "nobly done;" when noting the discovery of anæsthesia she would add the words *cum magna laude* so dear to every scholar's heart; but when she came to write of the physician of the last quarter of the nineteenth century she must say: "Many sons have done well, but thou excellest them all."

President's Address.—Dr. John A. Wyeth of New York delivered this address. (See page 921.)

Oration in Surgery.—The evening session was devoted to the delivery of this oration by Dr. H. M. Sherman. (See page 934.)

SECTION ON PRACTICE.

First Day—Tuesday, June 10.

Address of the Chairman.—Dr. Frank A. Jones of Memphis, Tenn., considered the standard of education necessary for a student to begin the study of medicine. French, German, Greek, Latin, and mathematics he considered accomplishments, and it stood the student well in hand to know them, but he did not believe that without them he was incapacitated to study medicine. He pleaded for a better knowledge of English. It was a source of gratification and pride to the medical profession of this country that there were some well-endowed medical institutions, and he predicted that the time was at hand when public-spirited, rich men of affairs would recognize the importance of endowed medical institutions and donate funds.

If a student possesses a high school education, if he knows English grammer, if he knows rhetoric, he thought he should be qualified to study medicine in any English speaking school. If he had a fair knowledge of languages, so much the better for him, although it was not an absolute essential. It was his opinion that if the student had an English qualification, a four years' course of eight months each should be all that could be asked for.

National Board of Examiners.—He requested the advisability of forming such a board on account of the expense attached to going to and from the place of meeting. He believed that each State should have, as most now have, an examining board composed of representative men, and if a student was going to that State to practice, passes a satisfactory examination before that board, then he should be entitled to practice. He believed that we should encourage reciprocity between State boards.

Amœbic Dysentery in Michigan.—Dr. George Dock of Ann Arbor, Mich., read this paper. From the facts detailed there could be no doubt the case reported was one of amœbic dysentery, the first he had ever seen or heard of in Michigan. It recalled to him many interesting facts in the history of dysentery and of the amœbæ found in the stools. Although dysentery was early looked upon as a disease of the tropics, largely owing to Kartulis's epoch-making observations and the striking relation of amœbæ to "tropical" liver abscesses, it could not be forgotten that the parasites were first recognized in St. Petersburg, and in chronic dysentery. He claimed that the amœba coli was probably a parasite having a world-wide distribution. The discovery of the amœba in different parts of the country and the results of the work of Councilman tended to fix its geographical and anatomic relations, as well as the clinical features of the disease. We must still learn the exact relation of the amœba coli to dysentery and intestinal ulceration, not to mention the remoter complications in the liver and thoracic organs. In view of the fact that Gasser produced colitis in cats by injections of garden earth, Sorgo, with non-amœbic dysenteric dejections, and also the fact that the previous observers have usually produced lesions not identical with those in human amœbic enteritis, we must await further observations. The occurrence of amœbæ in the stools of persons apparently well, or in those of patients with cholera or other diseases, or in the fæces of lower animals, cannot be considered proof that the amœbæ found in dysentery have no pathogenic relation. From certain observations he was of the opinion that it could be assumed that amœbæ are not present in about one-half of all normal intestines, in all parts of the world. In the literature upon this subject there were many contradictory observations, and the subject had been still further confused by premature efforts at nomenclature.

Dr. McCrae of Baltimore said that several years ago, he had seen one case with Dr. Osler occurring in a man who had never been out of Maryland, which contradicted the assertion made that all cases came from the South. The disease was not infrequent in the State of Maryland. A point of special interest was the increasing number of cases occurring in children. A majority of such cases followed the ingestion of gutter water from the streets.

Dr. James J. Walsh of New York has seen two such cases occuring in New York; in one of these the patient had never been outside the State.

Dr. E. Libman of New York referred to the occurrence of a large number of cases of liver abscess seen at Mt Sinai Hospital.

Dr George Dock of Detroit said that he wished to state that he did not include in his paper the possibility of infection from soldiers returning from Cuba or the Philippines.

The Origin of the Vesicular Respiratory Sound.—Dr C. F. Hoover of Cleveland read this paper. The origin of vesicular breathing was attributed by Laennec to friction of the inspired air in the bronchioles and its entrance to the infundibula from the bronchioles. This explanation was questioned by Skoda and others, and remained unquestioned until Baas attempted to explain upon purely acoustic grounds the impossibility of any audible sound originating in tubes the size of the bronchioles from the passage of a current of air with the slow velocity which must attend the entrance of inspired air in the vesicles of the lungs. Penzoldt, later, offered experimental evidence to sustain the logic of Baas. His experiment consisted in inflating a calf's lung and placing it over the trachea of a man, who was instructed to breath in the ordinary manner; if a stethoscope be placed on the inflated lung the observer will perceive the tracheal breathing transformed to the vesicular type of respiration. This is accounted for by the refraction and partial reflection of sound waves, which must occur during their transmission through such heterogeneous media as are presented in the inflated lung. If a more homogeneous medium be used, such as a calf's liver, the tracheal breathing retains its so-called bronchial character. Sahli tried the experiment as described by Penzoldt, but found that the respiratory murmur transmitted through the inflated lung retained its bronchial character. The only modification, according to Sahli, is a diminution in the intensity of the respiratory sound. His own observation confirmed those made by Sahli. In repeating this experiment it seemed to him that only a vigorous use of the imagination could transform the audible sound into a vesicular murmur. Vesicular breathing and bronchial breathing have several differences which will not admit of the transition of the former into the latter on the accoustic grounds cited by Baas. The term sound and murmur are differentiating terms, which are descriptive of the two phenomena. Bronchial respiration gives a clearly definite and simple sound, which can be assigned to a certain pitch. Vesicular respiration gives a confused mingling of sounds, which suggest a multiplicity of points of origin. The pitch is much lower and the respiratory sound is of shorter duration than in bronchial breathing. However remote and faint bronchial breathing may be the long duration of the expiratory sound remains the same, whereas in vesicular breathing the expiratory sound is relatively short, whatever may be its intensity.

The Causal Relation of Blood Poverty to Gastric Ulcer, with Report of an Illustrative Case with Atypical Findings.—Dr Robert N Wilson of Philadelphia read this paper. With regard to the causation of peptic ulcer of the stomach, he concluded (1) That in many, perhaps in most cases, a high grade of anæmia precedes the appearance of the peptic ulcer and that this anæmia usually assumes the chlorotic form; (2) That, with few exceptions, gastric ulcer is attended by the symptoms of marked anæmia. In certain cases in which the blood picture fails to show a reduction in the hæmoglobin percentage and in the number of red cells the fact seems to be due to concentration of the blood dependent upon anæmic causes; (3) That general anæmia means anæmia also of the pylorus, and consequent inanition of its mucous membrane; (4) That the venous outlet from the pylorus is one that in anæmic subjects would predispose still further to an unhealthy condition of the muscular and membranous coats of the pyloric wall; (5) That hyperacidity is usually present in chlorosis and often in other forms of anæmia, and that when present in any conditions it is an influence predisposing to gastric ulcer when associated with an anæmic gastric wall; (6) That hyperacidity is not essential to self-digestion of the stomach wall provided that wall lack proper nourishment and stimulation from a healthy or sufficient blood supply; (7) That any form of hemorrhage, menstrual, operative, or anemic, may either predispose to, or accentuate, an already present anæmic condition of the gastric wall, and that such hemorrhages are *de facto* often followed by gastric ulcer; (8) That the foregoing facts, in association with the general rule that gastric ulcers are seen almost invariably in anæmic subjects, warrant the conclusion that blood poverty is a leading and the usual predisposing cause of peptic ulcer.

Dr Fenton B. Turck of Chicago called attention to observations made showing that one of the chief factors in the causation of gastric ulcer was lack of motility. He also referred to a report in which it was shown that ulcers appeared in the jejunum after a gastro-enterostomy; here there was a lack of motility, together with some disturbance of the splanchnics and, especially, the liver circulation resulting in a peptic ulcer of the jejunum. In his own observations, carried out one year ago, confining guinea-pigs and rabbits in a cage of small dimensions, kept constantly darkened, of the few that lived some showed the chlorotic type of blood, and in some of these there appeared peptic ulcer. His own opinion, from a purely clinical standpoint, seemed to show the influence of two factors, the disturbance of the circulation and the lack of gastric tone, or motility, a condition sometimes called myasthenia.

Dr James J Walsh of New York said it was a well-recognized fact that an anæmic condition was the basis of gastric ulcer always. He referred to the traumatic causation occurring, as it does, in those using vibrating machines, such as knitting machines, typewriters, etc.

Dr H B Favel of Chicago referred to the active determining factor in cases of gastric ulcer, the lack of hæmoglobin; he considered this the active determining cause, and wished to emphasize it on account of its importance in the subject of therapeutics.

Dr Elmer Lee of New York said that such a condition could not take place in a strong, healthy being; to have a perforation of a human stomach there must be some lowering of the vitality, such as an under-nutrition.

On the Association of Graves's Disease and Glycosuria.—Dr Heinrich Stern of New York said the association of glycosuria with Graves' disease may occur: (1) As alimentary glycosuria e saccharo; (2) As spontaneous transitory glycosuria; (3) As diabetic glycosuria. Under the ten cures of Graves's disease, which he had seen within two years, alimentary glycosuria could be induced in one instance. Transitory glycosuria, associated with morbus Gravesii he had seen in one case, a negress, forty-one years of age, who soon died after this association had arrived. He had also seen a case of Graves' disease associated with true diabetes mellitus. He said there were altogether twenty-four cases reported in which the two affections have occurred at one and the same time. This case was the only one as yet described by an American observer. He said the association may occur in one of the following ways: (1) Diabetes antedates Graves's disease; (2) Both affections are produced contemporaneously; (3) Diabetes ensues after Graves's disease is fully established. When both affections are produced at the same time or when Graves's disease is the original and diabetes the secondary affection, there must be an interdependence. This interdependence is shown by the comparative frequency of alimentary glycosuria e saccharo in hyperthyroidism; it is also demonstrated after thyroid medication, when it occurs occasionally. It is not due to hyperthyroidism as such, but to a ferment not occurring in the thyroid secretion.

Dr E. F. Wells of Chicago said that when he considered the frequency with which Graves's disease is encountered, and the frequency with which diabetes is encountered, it was to him remarkable that only twenty-four cases should be found in the literature in which they were associated. It was also strange when we consider that the two affections, in many ways, were so nearly related. For a number of years, in exophthalmic goiter, he had derived much benefit from the use of cocaine in fairly large doses; the beneficial use of this drug, of course, was well known in diabetes. He used the drug in doses of from one-half to two grains in the twenty-four hours.

Dr. Jones of Buffalo said he had recently, in his private practice, an obese man, of middle age, who presented the ordinary symptoms of lithæmia, with urine of high specific gravity, with a sediment full of uric acid, pulse of low pressure, small and weak, a feeling of weariness, pain in the back, etc. His urine also contained a large amount of sugar, except when he was on an absolute diet. The slightest departure from an albuminous diet was followed by the presence of from thirty-six to forty-seven grams of sugar in twenty-four hours. The patient, when given ten grains of thyroid extract in a day, had an increase in the amount of sugar.

SECTION ON SURGERY.

First Day, June 10.

Chairman's Address: Surgery of Tuberculous Cavities of the Lungs.—Dr. DeForest Willard of Philadelphia presented this paper. The great trouble, he said, with all such operations would be to obtain the patients' consent to the operation. Though he had operated numberless times on animals, he had never had a human case. The results had not been very satisfactory and the operation was a very difficult one to perform, as it stopped free respiration, the lungs collapsing in the maority of the cases. It was necessary to have the lung adherent to the parietal wall of the thorax in order to prevent collapse. Those cavities in the posterior portion of the middle lobe are usually streptococcic in origin, and have given best results after operation. Successful cases had been reported by many. Allison and Ferguson had reported thirty-seven cases. In regard to the various operations there were mentioned: (1) Compression of the lung by nitrogen or other harmless gases; (2) Resection of the rib; (3) Cauterization of the surface of the lung and lung substance; (4) Injection of various materials into the cavities; (5) Incision and drainage—pneumonmotoy; (6) Pneumonectomy. The last two had given a certain percentage of beneficial results, and cures in some cases. Cough was lessened and expectoration diminished. An important step was to locate the cavity with the *x*-ray. After the pus had been evacuated, the cavity should be mopped out and then zinc chloride applied in small amount. Chloroform should be used in small quantities, as there was little or no pain after the integument had been cut through. Two inches of the rib should be taken out, care being taken not to injure the pleura. Pneumonotomy gave Puffier one cure, which is now four years past to the time of operation. In conclusion, Dr. Willard said that pneumonotomy was both feasible and helpful in early cases of tuberculosis; but it was most difficult to get this sort of a patient to submit to an operation; also that no cures had been reported in those cases in which both streptococci and the bacillus tuberculosis were present. Incision and drainage, with pneumonotomy, gave beneficial results. Pneumothorax was a possible and serious complication, hence the operation should not be done unless one had at hand a Fell-O'Dwyer or Matas instrument ready to do artificial respiration. An efficient means to procure adhesions must always be employed in doing the operation.

The Surgical Treatment of Pulmonary Abscess following Lobar Pneumonia.—Dr. Floyd W. McRae of Atlanta Ga., said that his paper had been burned in the fire which took place last night and begged that he might be permitted to present his subject extemporaneously. The diagnosis of these abscesses seemed to give a great deal of trouble both to the general practitioner and the surgeon. It would be found that a short while after the pneumonia had disappeared the patient started to cough, got up a temperature and other febrile symptoms, all of which would suddenly disappear after the patient had coughed up the pus in the cavity. The physical signs were large moist râles, with dulness, alternating with tympany. There are metallic sounds both on auscultation and percussion. Bacteriological examination of the sputum is most important. The pus does not often show the tubercle bacillus. The pneumococcus is the most important organism in the diagnosis. The first case reported showed complete cure after a period of forty days following the operation. The second case had existed six years, with periodical attacks of coughing up large quantities of pus. Pneumonotomy was done on the lower left lobe, concretions were found in the walls of the cavity and these were curetted away. The cavity was packed with gauze and drainage tubes put in. The operation had been performed five months ago and the drainage tubes were still in place, though the patient was almost entirely free from disagreeable symptoms. The mortality is due to the fact that most of the patients are in a low state of vitality, and hence cannot resist the shock of the operation. In performing the operation, the ribs at the lowermost point of the abscess should be removed as drainage was thus much better. The mortality in the cases on record was about 20-25 per cent., but this would be materially reduced by an earlier diagnosis of the condition.

A Contribution to the Surgery of the Lung as Based upon Original Observations.—Dr. Horace J. Whitacre of Cincinnati presented this paper, which was based upon 978 autopsies which had been performed on tuberculous cases. These showed that the pleural cavity can be opened without reference to adhesions, as in many instances the lungs showed tuberculous involvement without adhesion in the neighborhood of the lesion. Excision of tuberculous material in any part of the body must be thoroughly performed, if one hoped to cure the condition. The autopsies showed most conclusively that in the apices alone was the disease ever circumscribed, and only in these cases could one hope for a successful outcome by operations. When the circumscribed areas existed, it was often impossible to make out the condition, hence operation for this condition was impossible. If such a cavity should exist in the apex, drainage would not cause a contraction of the cavity, but from the anatomical relations the portions of the lung would be drawn toward the chest wall. In none of the essayist's cases was the cavity the seat of the infection. The majority of patients with cavities did not have a temperature or cough of any annoyance. It was not possible to say when a cavity was healed. Most of the patients with cavities had died with miliary tuberculous. Tubercle bacilli in the sputum should be considered a contraindication for operation. Nitrogen compression gave the most promise of all the methods suggested in these cases. Only 4 per cent. of the autopsies showed a condition which would be considered as typical for operation.

The discussion of these two papers followed.

Dr. O. C. Smith of Hartford, had operated upon three cases of pulmonary abscess, one recovered. In this case the patient had had a buccal abscess which produced the lung abscess. This speaker thought the operation might prove a "life saver."

Dr. Mayo of Rochester said that the first requisite was sufficient room in which to operate, and the second was to secure adhesions by tying the lung down by suturing it to the skin with a wet piece of gauze laid between the two layers of the pleura. Often bands running across the cavity could be felt by the finger [illegible] Thus, should not be [illegible] as they were the [illegible]

[illegible] said that [illegible] as frequently as reported, [illegible] to the chest wall [illegible], with most favorable results.

Dr. [illegible] of Cleveland thought it best to turn the patient on the side on which the cavity was to be drained, as in this way the contents would be less liable to get into the [illegible] cavity.

Dr. Oliver of Cincinnati advised surgical intervention in certain of the cases, as many patients might be materially helped.

Dr. McRae, in closing the discussion, insisted upon the importance of adhesions being formed before the incision was made.

Dr. Whitacre said that the majority of the cases of empyema were the result of abscess of the pleura, which had ruptured into the pleural cavity. To operate hoping to find adhesions was not justifiable, as he had shown in the study of the cadaver.

Report of a Case of Encysted Dropsy of the Peritoneum, Tuberculous in Character, with Hernia of a Portion of the Cyst; Operation; Recovery; Light and Air as a Curative Agent in Tuberculous Peritonitis.—Dr. Miles F. Porter of Fort Wayne, Ind., said that all forms of tuberculosis of the peritoneal cavity will heal and get well on simple medical treatment alone. Cœliotomy brought about cure by no single factor alone, but all the theoretical factors put forward by many writers and authorities played a part. Light and air, trauma, x-ray, and the actinic rays were all useful, but literature showed that light and air gave the best results. Ascitic forms are the most favorable for operation. The inoculation of the peritoneum with putrefactive bacteria is too dangerous an operation to be considered seriously. Drainage should not be used unless there be present a mixed infection.

The case reported was one with a large tumor above the symphysis pubis, which look at first like a hernia with the bladder included. After the skin and fasciæ were cut, a solution of potassium permanganate was introduced into the bladder, and then a hypodermic needle was introduced into the sac to draw off some of the fluid. It was found to be clear. The excision of the sac showed the tumor to be cystic and tuberculous in origin.

Dr. Ransohoff of Cincinnati, in opening the discussion, remarked that the time was not distant when the diagnosis by means of the x-ray would make many surgical operations unnecessary. The most successful operative cases were those in which tuberculosis of the peritoneum was suspected before the operation. The less these cases were interfered with the better would be the results.

Dr. Halstead of Chicago has had eight of these cases and not one has resulted in recovery. Cure is produced by the trauma to the parts. The intestines must be wiped dry before the abdomen is closed. In chronic cases where there were several cavities, each one should be drained for a time. The old idea that the disease is secondary to tubal tuberculosis is wrong, as the latest statistics show but 1 per cent to be secondary to tubal disease.

Dr. Robert F. Weir of New York said that it must be admitted that it was not known in many instances how the cavity is infected by the disease, but probably it is by the tubes or the intestinal tracts. The treatment must depend upon whether the fluid is general or is encysted. Probably the cure was induced by the reaction on the circulation in the parts due to the operation of opening the peritoneal cavity.

Dr. Ochsner of Chicago concluded that 50 per cent of the ascitic cases which are acute get well without surgical intervention, hence they are non-surgical. The acute cases which do not get well with medical treatment are not benefited by operation. Surgical treatment is [illegible] indicated when [illegible] cases have [illegible] there are formed adhesions and pockets. There are cases where the whole pelvic contents are matted together [illegible] drainage will produce cure.

Dr. Ernest La Place of Philadelphia held that tuberculous peritonitis was of two varieties: (1) When the tubercle bacillus alone was present, and (2) When there was a mixed infection. The first class required but mild irritation to produce a cure.

Dr. Tiffany of Baltimore said that the congestion resulting from the operation brought on the cure.

Dr. Porter, in closing, said that every means should be employed in each case, as what might fail to cure one case would possibly heal another. It was certain that no variety of tuberculosis could be cured by the formation of adhesions.

Low Lateral Pharyngotomy for Approach to the Lower Portion of the Pharynx, Upper Portion of the Œsophagus and Posterior Surface of the Larynx, with an Illustrative Case. Dr. Joseph D. Bryant of New York presented this paper, prefacing it with the minutiæ of the surgical anatomy of the region, and described the technique by which the lower portion of the pharynx was reached to remove a fibrosarcoma in the larynx. The tumor was five and a half inches from the teeth and fixed. It was just possible to touch it by introducing the finger into the mouth of the patient. Since the operation the right vocal cord has been paralyzed, though the right recurrent laryngeal nerve was not injured during the operation. There had been [illegible] previous cases in which this operation had been performed, but in none had it been done for the removal of a tumor. This was the first recorded tumor excision by this route.

Dr. Allen of Cincinnati added another case to the list recorded by Dr. Bryant, but the patient died ten days after the operation from pneumonia.

Dr. Lutz of St. Louis advised the use of local anæsthesia in all such cases, as there was less liability of dysphagia and dyspnœa afterward.

Dr. R. H. M. Dawbarn of New York thought it inadvisable to sew up these cases after the operation, and that a great deal of the ultimate success depended upon the after-treatment. Hot oil, rubbed into the skin four times in twenty-four hours, with milk peptonized to buttermilk given per rectum, would give an efficient means of supplying food until the wound was entirely healed.

Dr. Bryant remarked, in closing the discussion, that he did not consider the route taken very dangerous, as some of the gentlemen had remarked. The tumor, by this means, could be easily removed without opening the larynx, as it was very readily enucleated by the finger hooked about it. The greater cornua must be held away from the field of operation with a tenaculum, and at the same time, drawn forward.

SECTION ON OBSTETRICS AND DISEASES OF WOMEN

First Day, Tuesday, June 10

Chairman's Address.—Dr. J. H. Carstens of Detroit read a paper on the future of women under the extraordinary conditions of modern life. He dilated on the strain which menstruation imposed on school girls, and expressed the belief that the duties of the [illegible] should include instruction of the mother in the care of her daughter. A period of rest should be imposed during the menses, and therefore he believed coeducation had its disadvantages, the male student being able to continue while his sister was forced to rest. He emphasized the many nervous ills arising from neglect of such rest and the consequent poor physical and mental stamina of the offspring. Attention was called to the large number of papers on what might be termed the mechanics of obstetrics and gynecology, and the exceedingly small number of physiological papers on obstetrics and the relations of the growing girl to her work in life. That they should be instructed as to the best line of work that would suit the individual case, *e.g.* music, typewriting, sewing, or mental work, such as the work of the school teacher, physician or lawyer. He deplored the suggestions to the growing girl as to her pelvic organs; the unnatural anxiety of her mother and friends kept up a constant train of thought that would in the end bear fruit and lead her to seek aid when none was needed. He desired to warn the members of dietetic derangements. The physician could, in these cases, do an immense amount of good by looking ahead and guiding the future race.

The Permanent and Harmless Results that Should Constitute the Normal Minimum Requirement of Surgical Treatment of Complicated but Aseptic Retroversion of the Uterus in Fruitful Women, and by What Methods They Are Best Obtained.—Dr. A. Goldspohn of Chicago read this paper. He condemned all other operations, such as ventrofixation, vaginofixation, and ventrosuspension as of no practical value in women who had a reasonable capacity for conception. He desired to note that retroversion does not cause death or interfere with the sexual pleasures. He objected to major operations, believing the simple operation best—one that will produce a permanent result, not interfering with conception and not followed by return after child-birth. He maintained that ideal results were obtained without redisplacement after pregnancy. He considered unjustifiable all median, ventral, and vaginal sections, as they strengthen the strongest portions and leave the distal weak ends to bear the strain. He believed the suspension methods the best of these, but no one could tell how soon the ligaments would stretch, as during pregnancy they do not grow, and do not retract or undergo involution afterward. The shortening of the round ligament was best done through the inguinal canal from without. The round ligament grows during pregnancy and undergoes subinvolution in connection with the uterus. The shortening is done at the weakest portion, leaving the stronger at its uterine attachment. The objection had been made that hernia would result, but this could not occur if the wound was properly closed. He also stated that the adhesions which may be present could be readily reached with the finger through the internal abdominal rings, liberated, and repairs made to the adnexæ. The uterus was brought nearer to the proper position; the operation did not disturb or interfere with the functions of other organs, it was without mortality, and had a lower rate of return after pregnancy, there being practically no return of retroversion.

Surgical Treatment of the Uterosacral Ligaments through the Vagina in Retroversion of the Uterus.—Dr. J. Wesley Bouvée of Washington, D. C., spoke of the useless treatment in vogue for retroversion, the pessary, tampon, curette and position treatment. While many were benefited, the ultimate results were not satisfactory. He did not desire to condemn this treatment where the symptoms were minor, yet believed the conditions continued, and with the cessation of treatment the greater the necessity for radical treatment. The reader gave a description of the uses of the various ligaments in uterine support; how the uterosacral, uterovesical, broad and round ligaments each had a share in maintaining the uterus in proper position. No operation should be condemned, yet the shortenings by vaginal methods was in the weakest portion and was anatomically wrong. He suggested a more careful examination to determine the non-existence of some causes other than weak ligaments. The round ligaments hold the uterus forward and if the shortening has been too much there will occur during pregnancy a pressure upon the bladder. The operation which he desired to endorse, in relaxed condition of the posterior vaginal wall and a short anterior vaginal wall, was opening through the posterior wall on one side, bringing down the uterosacral ligaments and tying them; then the other side treated in the same way. All adhesions were liberated posterior to the uterus, and the wound was closed. The danger of opening into the peritoneal cavity was not great and could be avoided. He claimed no better results were secured from the other operations, especially the operation of shortening the round ligament. The number of recurrences, both with and without pregnancy, were small. All adhesions must be removed, but he did not consider this a dangerous operation.

Dr. Reese of Chicago, in opening the discussion, spoke of the Alexander method as the best known for retaining a retroflexed uterus in position. He maintained that, as a matter of fact, no one knew how the uterus was kept in place, yet this did not prevent the use of the ligaments that were known to bear a relation of support or suspension to the uterus, and these could be used in keeping the body in position. He said the results in shortening lateral ligaments were not as satisfactory, and care must be exercised to prevent openings into the peritoneum.

Dr. Goffe of New York believed the round ligaments to be the true support. The uterus was a suspended organ, and it was supported like other suspended organs in other parts of the body. The uterus maintained its position by the uterosacral and vesical, the broad and the round ligaments. He did not consider the ventral fixation of value, there the tissue is weak and stretches during pregnancy. The round ligaments grow and involute after parturition. He considered the round ligament the most useful of the many. They not only support, but they hold the uterus from the bladder and the abdominal wall during pregnancy. The uterosacral ligament has many points in its favor, to suspend the uterus and reduce version. To compare the ligaments, he believed both were important and were the physiological ones to hold the uterus in position.

Dr. A. Palmer Dudley of New York spoke of retroversion as being the direct cause of pelvic infection, of extra-uterine pregnancy, and of pus in the Fallopian tubes. He also believed ventrofixation to be unsurgical, but ventrosuspension was safe and practical, and had produced results which were as good as those following the Alexander method. He compared the diaphragm as a reduplication with the floor of the pelvis, there being a fibro-elastic band, each maintaining a definite supporting relation to the uterus. He believed there were more retroflexions than retroversions. He objected to the buried suture, there being great danger of penetrating the peritonium. He endorsed the open method and used the peritoneum as one item of support. He endorsed ventrosuspension, Alexander's method being of use only when there are no adhesions.

Dr. Goelet of New York desired to emphasize the importance of doing the operation properly. He endorsed the ventral suspension and also the shortening of the round ligament. He said the adhesion when broken up reforms and causes failure by stretching the round ligament.

Dr. Walther thought both methods are limited. He thought better results are obtained by opening the abdominal cavity and meeting the pathological conditions as presented, removes adhesion and then operate according to the best judgment.

Dr. Harrison of New York remarked when the uterus is fixed there is a pathological condition that should not be forgotten and conditions met.

Dr. Cohen of Buffalo desired to mention the neglect of after treatment of pregnancy as one of the factors causing retroversion.

Dr. Carstens of Detroit desired to point out the relaxing condition that takes place in all the organs and a pushing down into the pelvic cavity.

Dr. Goldspohn, in closing, claimed the operation was not Alexander's operation. He said it was easy to break up the adhesions with the finger. He claimed this operation was far ahead of any other operation in clinical results and he desires the proof in detail cases.

Dr. [illegible], said he opened the peritoneum if necessary; the intestinal loop need not be caught if care is taken. The ligament was brought to view and [illegible] before cutting. Labor following [illegible] operation gives as favorable results as after any other method. He believed if the cervix was in the hollow of the sacrum there would be no retroversion.

Electrothermic Hæmostasis.—Dr. A. J. Downes of Philadelphia in this paper referred to a previous one on this subject. He said this method had special claims for uterine cancer, salpingitis, and extrauterine gestation operations. There was less danger of infection, of formation of adhesions, and [illegible] surfaces. In cancer of the uterus the operation had a curative effect, destroying the germs and preventing infection. He said it could be used successfully and safely in place of the ligature.

Rectovaginal Fistula.—Dr. A. Palmer Dudley of New York described in this paper an operation for rectovaginal fistula in which the mucous membrane of the rectum was loosened up above the fistulous opening, was then brought down and cut off, the fistulous openings in the vagina were repaired, and the mucous membrane of the rectum brought down and attached. The reader considered this method was the best for this trouble, as it was followed by better results than any other method.

SECOND DAY, WEDNESDAY, JUNE 11.

GENERAL SESSION.

Oration on Medicine, by FRANK BILLINGS of Chicago. (See page 941.)

SECTION ON SURGERY.

Further Experiences with a Modified Method for the Cure of Relapsing Talipes Equinovarus.—Dr. A. F. JONAS, Omaha, Neb., read this paper. He said that it was easy to correct this deformity, but it was very difficult to keep it in good position after the operation. Relapse was so liable that the operator would often get discouraged. In chronic cases the plantar surface pointed in and backward. It was a great problem to bring about a permanent cure, for the disease occurred among the poorer classes most often, who could ill afford to buy the expensive apparatus necessary to keep up the results of operation. The main indications in doing the operation are to elongate the soft part on the inside of the foot and to replace the bones into a normal position. Over-correction of the deformity did not always produce a cure, as the resulting contraction of the scar tissue often was greater than could be anticipated. The Phelps operation was a good one, but the resulting open space was often hard to heal, so he advised the making of a triangular-shaped flap similar to the one used in the Dupuytsen's contraction in the hand. He would not enter the astragalo-scaphoid joint, but cut off the neck of the bone without entering the joint. He also advised the cutting of the tendo achillis. It was his habit to employ the triangular flap even in acute cases. In conclusion it was advised that the open operation always be employed to reduce the talipes equinovarus. (2) To avoid cutting the astragalo-scaphoid ligament. (3) that the neck of the astragalus must be divided with the osteotome. (4) That the internal lateral ligament must be divided in the rotation outward. (5) To prevent relapse he divided the soft parts with the bone.

Prevention of Deformities.—Dr. W. R. TOWNSEND of New York City said that the prevention of deformities should be the aim of every medical man, since more than 50 per cent. of the deformities resulting from anterior poliomyelitis could be prevented if taken in time. The original lesion was not a deformity but simply a weakness of the muscle. Too much time was spent playing with electricity and not enough preventing a resulting deformity, and gravity entered in as a factor in the deformity. Talipes equinovarus was classified by him as (1) [illegible], acquired, (2) Paralytic, (3) Traumatic, such as followed a fracture. Of [illegible] cases seen by the writer over one-half were congenital [illegible]. Massage and proper sets of splints prevented deformity in the majority of instances. In chronic joint disease the treatment should always be to prevent a future deformity as well as to cure the disease. After operations on muscles and bones splints must be worn for a long time. In pyæmic and rheumatic joints the possibility of a resulting deformity must always be borne in mind by the general practitioner. Foot-drop after [illegible] can be prevented if the foot be kept at right angles to the leg. Plaster of paris splinting was the best method of preventing deformities. Contractures after typhoid fever were avoided if the doctor or nurse made daily tractions on the patient's legs.

Dr. H. L. TAYLOR of New York City thought it wrong to postpone treatment in the hope that the patient would outgrow deformities. The deformities following Pott's fracture and those about the elbow were prevented by treatment.

Dr. H. A. SHERMAN of San Francisco abandoned Phelps's method years ago and has used frequently open and subcutaneous cutting of the soft parts and the bones. Relapses were due to faults in the deeper structures and not in the integument.

Dr. STEELE of St. Louis thought that very few cases of club foot require interference with the bone; they can be cured by subcutaneous division of the muscles and ligaments.

Dr. RUTH of Iowa had long since given up the V-shaped flap; he thought that sectioning of the bones was not necessary before the fourth year. The removal of the astragalus had cured some of his marked cases.

Gunshot Wounds of Cavities.—Dr. W. L. RODMAN of Philadelphia divided wounds of the thorax into penetrating and non-penetrating. Penetrating wounds usually involved the lung. Hence he did not consider those of the heart which were too rare to be taken into account. The diagnosis was made on severe shock, local and general emphysema and hæmoptysis. Hemorrhage usually was due to the severing of the intercostal artery. The diagnosis should never be made with the probe, which almost always produced empyema. If these wounds did not kill within twelve hours the patients got well unless infection happened. He treated the cases by strapping and the administration of opium internally. Lodged balls should be let alone as they did no harm. Abdominal wounds were divided into (1) Penetrating and (2) Perforating. The latter entered either the solid organs or a hollow viscus. 3 per cent. of the penetrating wounds did no harm to the organs, according to statistics. The speaker thought this too low; wounds of the upper portion of the abdomen are less liable to penetrate the organs, hence the prognosis in such accidents is better than that of wounds below the umbilicus. Antero-posterior wounds were less serious than lateral wounds, which in turn, were not so serious as those from flank to flank. The prognosis of gunshot wounds of the abdomen was always grave, and they should always be operated upon. Cases operated upon in the first four hours gave a mortality of 15 per cent. Hence the advantage of early operation, as there was little liability to fecal extravasation. The first thing that took place after the bullet entered the gut was a contraction of the circular muscle fibers, then paralysis followed by an ectropion of the mucous membrane of the gut, preventing an escape of the fæces. Even though best results were obtained in early cases, delayed operations should be done. In treating these cases the wounds were first covered over with gauze, to prevent the escape of fæces from the gut. Intravenous injection was also done. In civil practice because of the large bullets and slow velocity, septic material was always taken in, hence drainage must be employed.

In the lesser peritoneal cavity posterior drainage was absolutely necessary. It was not necessary to take out the ball, as a ball which has ceased to move is harmless.

Dr. McGraw of Detroit thought that a ball never ran around the abdominal wall, but contraction of the abdominal muscles were taking place at the time of the injury, and these shoved the intestines to one side and the bullet passed straight through the abdomen without touching the hollow organs. The empty intestine gave a good prognosis. It was sometimes best not to wait for perfect asepsis in operations, for too much valuable time was lost.

Dr. Grant of Denver said that Army Surgeons were averse to an early operation on the field of battle. They advised absolute rest and withheld all fluid.

Dr. J. C. Oliver of Cincinnati affirmed that if thoracic cases do not die in twelve hours their chances were excellent. The principal of rest was necessary in these cases.

In abdominal cases a certain percentage were primarily fatal, regardless of the time of operation or treatment; 5 per cent. of the cases showed gross fecal extravasation. More cases of gunshot wounds of the stomach got well without operation than with it. Vomiting of blood did not always indicate wound of the stomach wall. Shock was not ordinarily a marked feature. Drainage was always along the track of the bullet.

Dr. J. B. Roberts of Philadelphia said that venesection should be done on the outset of pneumonia following gunshot wounds of the lungs.

Dr. R. H. Gibbons of Scranton, Pa., insisted upon the importance of the catheter in the diagnosis of injury to the bladder and its appendages in abdominal wounds.

Dr. Porter of Ft. Wayne, Ind., considered shock an indication for immediate operation, as it was usually the result of hemorrhage.

Dr. Rodman, in closing, said that military surgeons were right from their standpoint in not operating immediately on the field, as they had an incised wound to deal with, but in civil life we had a large leaden ball which made a lacerated wound, which was followed by fecal extravasation.

A Case of Unique Foreign Body in the Stomach.—Dr. J. C. Olner of Cincinnati, Ohio, reported a case of a young girl who had swallowed persimmons and complained of cramps afterward. Emetics and other medication was employed to get rid of the substance, which was easily palpable through the abdominal wall. As this method failed, the case was operated upon, and seven ounces of persimmon pits, shells, and twigs were removed. The patient made an uneventful recovery.

Dr. Jacobson of Maine had had a similar case, in which the patient had a large hair tumor, weighing one ounce less than a pound, removed from the stomach.

Intestinal Anastomosis.—Dr. F. C. Connell of Leadville, Col., reported a series of experiments, which were about the same as those done by Murphy and Senn of Chicago to show that air pumped into the intestines where there were intestinal perforations, became contaminated by sulphureted hydrogen in passing to the abdominal cavity. If this gas was taken out through the abdominal walls, the sulphureted hydrogen could be detected with the aid of lead acetate solutions, or solutions of iodide of starch or Nestle's reagent.

Gallstones in the Common Duct.—Dr. Martin B. Tinker of Baltimore read a paper with this title. He said that in one-third of these cases the symptoms had existed for at least ten years; when the stone was lodged permanently operation was indicated. In one-quarter of the cases the symptoms were of three years' standing. The methods of operation that had been advised were: (1) Cholecystenterostomy. None of these had been done at the Johns Hopkins Hospital. It was simply a makeshift, and was only to be used when the patient was in a bad shape; (2) The pressure of stones into the duodenum or the gall-bladder. This operation was not as simple as it looked. Mayo Robson said that success was an accident; (3) Crushing the stone is condemned by Fenger, as the débris may be left and form a nidus for new formations. Further it was only advisable where the stone was single. In only six out of twenty-seven cases was this the fact at Johns Hopkins Hospital; (4) Rapid cholecystotomy may be done for jaundice. It had been employed in two cases in Baltimore, where it was found that the gall-bladder had been ruptured; (5) Incision through the duodenum was more easy than cholecystotomy, but was more dangerous from its liability to infection; (6) Incision of the gall-bladder, with suturing afterward and drainage through the gall ducts. This operation was the one of choice. It prevented in many instances the dreaded cholecystitis and secondary operation. Twenty-one such cases with complete recovery had been done at the Johns Hopkins. T. M. T. Finney has removed the gall-bladder after stuffing back the serosa and leaving the peritoneal flaps in cases of cholecystitis with stones. Twenty-three cases of choleductotomy gave a mortality of 13.6 per cent. Points to be emphasized in gallstones were: (1) Early operation, and (2) and that the operation of choleductotomy was not more serious than appendectumy, but more difficult.

Surgery of the Gall Bladder and Bileducts.—Dr. A. H. Fergusson of Chicago, said that the anatomy varied most in the blood supply to the parts. There might be a blood vessel running directly across the common duct. The length of the ducts was not important, but their calibre was. The cystic was the smallest and the common duct the largest. The mucous membrane of the cystic duct was spiral in its arrangement, which might give a false conception of stricture. The displacement of the gall bladder was due to (1) The peritoneum about it; (2) The gall bladder was often absent entirely; (3) Pathological conditions, such as adhesions which may either drag it down or bring the surrounding organs toward it. Thus we may get residual bile with the formation of stones by the precipitation of cholesterin in the presence of some microorganisms. The most trustworthy symptoms were: (1) Every case gave some intestinal disturbance; (2) There was always localized pain in the gall bladder region on pressure, with an exaggeration of the referred pain wherever that might happen to exist; (3) The pyrexia was present in about 50 per cent. of the cases, even without the presence of germs. It might be due to the absorption of bile pigments or other bile elements. Putting two fingers into the foramen of Winslow made it possible to palpate for stones or other conditions in this region. The author had employed a modified Politzer bag to blow air through the gall duct to ascertain its patency; the duodenum was ballooned by this procedure. The gall bladder must always be fixed to the upper portion of the incision to prevent fistula. Hepatotomy was an effectual method to get drainage in cases of big liver and of suppression of bile.

Surgical Aspects of Pancreatitis.—Dr. W. J. Mayo of Rochester, Minnesota, said that the anatomical relationship existing between the biliary and pancreatic ducts caused gall-stone disease to be the most important etiological factor in the production of pancreatitis. The form which the disease took, depended upon the chemical or bacteriological invasion of the ducts. The acute form was usually attended by hemorrhage into or about the pancreas, and fat necrosis, involving the omentum, retroperitoneal and mesenteric tissues by preference; and might result in abscess, if death did not supervene. The symptoms were those of a most serious lesion, involving the upper abdominal zone with repeated attacks of collapse, nausea, vomiting, etc. The chronic form was mostly in the nature of an intestinal paresis, both enlargement of the liver, jaundice was a most prominent feature. The treatment of the acute form was to sustain life and keep down pain until recovery or take place. The treatment of the chronic form was by means of cholecystostomy [illegible] draining the ducts. The knowledge of the various forms of the disease has been so largely gained from the dead house that it is probable that many of the milder cases must have recovered spontaneously, unrecognized.

Dr. DAVIS of Birmingham, Ala., said that in the majority of gallstone cases the probing of the duct was unnecessary and very difficult. The ducts should always be drained if the gall bladder were removed. Hepatotomy was first done by the speaker in a case of abscess of the liver, and he had found that there was such a free flow of bile that the experiment was suggested for other lesions.

Dr. J. E. MOORE of Minneapolis said that more stress should be laid upon Mayo Robson's point as a good job in this region always elicited pain where bileduct or bladder trouble existed.

Dr. RANSOHOFF of Cincinnati wondered if we could promise the patient that there would be no recurrence of the disease. Every time a patient was operated upon in the gall bladder region some lesion was sure to be found, though it might not be the one for which the operation was undertaken. The transduodenal route was not the one of choice as it might result in cholangitis.

Dr. ROBERT ABBE of New York City said that time was of too much moment to permit of the suturing of the gall ducts.

Dr. ROBERT F. WEIR of New York City believed that the Dawbarn method of drainage was the most efficient one to be used in these cases. He advocated placing of a five-grain pellet of methylene blue into the gall bladder before fixing the drain, so that one might recognize that the ducts were draining by the presence of the drug in the stools after the operation.

Dr. H. O. MARCY of Boston remarked that he was the first to suture after the removal of a stone, but he now doubted the success of the operation. Exploratory laparotomy was justifiable to secure a diagnosis.

Dr. TUCKER closed by saying that inasmuch as the bile is almost always infected, suturing is the best method of protecting the peritoneum from infection. In the majority of cases the gallstone operation was not an emergency one, and such being the case, as much time as was wanted could be employed in doing the operation.

Dr. Fergusson did not find that recurrence ever happened. All cases should be drained and fulminating cases should have immediate operation.

Appendicitis; a Critical Review of 416 Cases Operated on at the German Hospital During 1901.—Dr. JOHN B. DEAVER of Philadelphia read this paper. Of the 416 cases, 279 were acute with a mortality of 15.3 per cent.; 137 were chronic, 7 per cent. mortality. Early operation was necessary and indicated. The ice bag gave a false sense of security and masks all the symptoms until perforation and death results. No case should be permitted to go on to pus formation, as formation of stricture has resulted and the mortality in these cases when operated upon is about 62 per cent. Hernia was usually the result of extensive drainage. The use of the white blood count to make the diagnosis was unreliable. It was only of importance in cases where the diagnosis was doubtful, but the diagnosis was always easy.

Appendicitis; a Brief Report of the Author's Nine Fatal Cases, with Comments.—Dr. PARKER SYMS of New York City read this paper and showed that death had been unavoidable in all of the nine cases; showed that five had had a gangrenous appendix with rupture of the bowel, three had free pus in the peritoneal cavity from suppuration of the appendix, and one was a case of circumscribed abscess, which had occurred after the patient had been turned over to the family doctor. Nearly all had had previous attacks and would have recovered had they been operated upon early or at the first attack. He said appendicitis was a purely surgical disease. Care should always be taken to protect the peritoneum from infection in operating upon these cases. Opium should never be used except for abdominal shock. If the treatment was to be ideal, then the mortality should be nil. Early operation must be insisted upon.

Some Anomalies in Appendicitis.—Dr. J. L. PEACE of Philadelphia remarked that appendicitis is an abnormal disease. It was not always easy to make the diagnosis. The appendix was not always present in the right iliac fossa; it might be lying under the liver or elsewhere. Pain was an uncertain factor in the diagnosis. Infection was the [illegible] of the disease. Streptococcus was the cause of gangrene. B. coli communis was the starter of the enteroliths so often found in the appendix. These cases have had previous attacks which may have been only sufficient to gradually produce a stricture above the enterolith. This stricture becomes firmer and more pronounced with each attack. The B. coli communis was the cause of the obliterating form of the disease. At no time during an attack can one state the condition in the appendix. Early operation should be done in all cases at all hazard.

Dr. ROBERT F. WEIR of New York said that he had found a new use for the useless appendix. In operating upon a case of dysentery the appendix bobbed up into the wound, and he made it fast to the skin and cut off its end. He then used it as a means of injecting medicine into the intestines to cure the dysentery. Early operation could not be too much insisted upon. When the diagnosis was made, one should operate. The disease caused more danger than the operation.

Dr. Abbe of New York, Dr. Ohlsner of Chicago, Dr. Murphy of Chicago, and many others joined in the discussion all urging early operations as the only means of lowering the mortality, and thanking Dr. Deaver for having solved the question of treatment of acute and chronic appendicitis.

SECTION ON OBSTETRICS AND DISEASES OF WOMEN.

High Amputation of the Cervix versus Hysterectomy for Operable Carcinoma of the Cervix.—Dr. C. C. FREDERICK of Buffalo read a paper, in which he demonstrated that the results of hysterectomy for carcinoma of the cervix in operative cases were not what the writings of some enthusiasts would lead us to believe or expect. A very small percentage are cured, the danger arising from peritonitis is very great, and infection is more likely than in amputation of the cervix. He showed that relapse was very common in the scar, not due to any fault of the surgeon at the time of the operation, or because of any carelessness on his part, but, as a clinical fact, it is very common. The other points of infection, as the body of uterus and broad ligaments, were not so common. The amputation of the cervix at or above the internal os was much simpler and far less dangerous. The operation is feasible when there is no infection of the surrounding tissues, and in the early stages. The writer believed these were the operable cases. The disease in the wall of vagina can be removed with safety. The results show that relapse does not occur to any greater extent; the results are as favorable as from hysterectomy, the patient does not suffer any greater pain, and the period of relief is as long. The patient is not kept in bed for as long a period, the shock of the operation is much less, and the results in general are as good. He urged high amputation of the cervix in all operable cases of carcinoma of the cervix as a very valuable and safe substitute for hysterectomy.

Dr. MONTGOMERY of Philadelphia acknowledged that high cervical operation was a method of great practical value, but he also felt that to do a thorough operation, the method adopted in amputation of the breast, with removal of axillary glands, was to be taken into consideration. He thought elimination of the surrounding lymphatic tissues was best accomplished by removal of the uterus in whole. These parts are rich in lymphatic vessels, the disease being carried by these and a small mass, too small to be felt by the touch, will escape observation, and be the source of reinfection. Sometimes the operation is the cause of spreading the disease, the germs being taken up by the open vessels and carried into the circulation, and a new focus formed. He believed it wiser to get beyond the disease. In no cases does the cautery act with better effect, the searing of the tissues prevents infection and ensures more thorough removal than can be obtained with knife or scissors. He believed the entire uterus should be removed. Statistics showed the mortality to be not greater than in the high cervical operation.

Dr. Taylor of Cincinnati believed that a larger number of these cases recover than is given by the writer. In the study of the subject he found that about 20 per cent are free from recurrence after five years. He acknowledged that this included all cases of cancer in the body and did not show the actual number of uterine cancer. Of the operable cases there were 10 per cent. improved, and the operation was justifiable when life can be extended to three months or a year. The more encouraging reports were from the early operations, the later cases, with more extensive disease, having a high mortality, even in those in which total extirpation of the uterus, with removal of appendages, is done. He favored a more radical operation in early cases, and found the use of the electro-cautery, in conjunction with the knife, very useful. Removal of the diseased portion and cutting through the uterus above the cervix do not always prevent a rapid return. He thought, however, that the rate of mortality is discouraging to the operator, and desired to endorse the high operation, with complete extirpation of the organ. When the case lasts six months there is an involvement of the appendages, and total extirpation of tubes and ovaries gives a better recovery, fewer recurrences, and more comfort to the patient.

Operation for Recurrence of Cancer after Hysterectomy.—Dr. E. W. Cushing of Boston read a paper in which he acknowledged that there was a large number of recurrences after hysterectomy; nevertheless many were saved, and the lives of many prolonged. The most modern method should be observed. He believed it essential to have an early diagnosis and a radical operation, this gives better results than were formerly secured. It was essential that no infection of the wound take place, and all the involved lymphatics must be removed. When the diagnosis is not made early there is infection which cannot always be readily recognized by examination. After operation it is essential for the surgeon to see the cases and examine them at intervals to note the early return and immediate removal of a small infected point. These cases should be observed for years. When the reinfection has involved the surrounding tissues he advocated an abdominal opening and removal of the diseased tissue. The reader described a case of this kind in which dissection of the ureter was necessary, and the pelvis had to be entirely cleared out. In this case the recovery was good. It was now two years since the operation, without recurrence; the patient had had no pain and her physical condition had improved.

Dr. Kolischer of Chicago said the term cancer of the uterus is unscientific, and insisted that cancer of the upper section of uterus, with involvement of appendages is different from carcinoma of the lower section. He thought there should be described two forms of hysterectomy, one in which the uterus is removed without appendages, and the other in which all the appendages, including broad ligament and ovaries, are removed. The bladder is the last organ to become involved; in only about fifteen cases out of 150 was there involvement of the bladder. He said the mortality lists show a heavy percentage in hysterectomy, there being about 10 per cent. of immediate deaths. The largest number of recurrences show an involvment of the tubes and ovaries. He said there could be no return in vaginal scar unless there had been carelessness on the part of the operator, the later endeavoring to hurry through and leaving a trace behind. He did not favor the clamp, as it crushes through diseased tissue and all cannot be removed. There are only about 8 per cent. of definite cures.

Dr. W. H. Warthen of Louisville said there are cancers involving uterus and broad ligaments, and others involving only cervix, and possibly the wall of the vagina. He believed that 99 per cent. of the first class are fatal, whereas those of the second class are much more favorable. According to him, statistics show from 10 per cent. to 25 per cent. recoveries. He believed that where involvement of the body has occurred the results have been better than are shown. He did not favor the entire removal of all the appendages and dissection of the glands.

Dr. H. O. Marcy of Boston said the discussion as to the best operation for the removal of cancer of the uterus had been going on for the past ten years, and would, in all probability, continue for ten years more, and no more definite and satisfactory method would be devised at the end of that time than was known at the beginning. He favored the high open abdominal operation and removal of all diseased tissue; yet he recognized that each case must be judged and the involvement of tissue taken into consideration. He favored a more radical operation as the safest for the patient.

Dr. A. J. Downes of Philadelphia referred to his paper of yesterday in which all ligature operations were said to show a recurrence in 99 per cent. He favored the clamp with the use of electro-cautery, and claimed a greater freedom from danger of infection. A broad ribbon of seared tissue results, with a non-exuding, non-absorbing surface. There are more recoveries than with the ligature and less loss of blood.

Dr. J. H. Carstens of Detroit said the more cancer cases he saw the less he favored the operation of hysterectomy, as the results are very poor.

Dr. C. C. Fredericks, in closing, stated that he had considered only operable cases in his paper. He had seen return of the disease in the cicatrix, and many of the best operators of the country know this to be true. The operation of hysterectomy results in death or recurrence in all cases. He did not believe it advisable or good surgery to remove a healthy uterus, because we fear the disease will recur, and the danger of peritonitis and infection is far greater than is acknowledged by the advocates of hysterectomy.

Dr. E. W. Cushing, in closing, said that removal of glands had immense advantages; there could be no greater infection than there was in cutting above the cervix. He had cases which had been operated on ten or twelve years ago and were alive to-day.

Hæmostasis of the Broad Ligament.—Dr. H. P. Newman of Chicago read this paper. In it he advocated the use of a pressure clamp on the broad ligament, the clamp giving a pressure of one thousand pounds. A ligature can be put on the large vessels in the usual manner on the proximal side, and the clamp then removed. He claimed that there results less infection, that there can be no slippings of the ligature as when a mass is tied, and there is no retraction of the stump. The crushing causes multiple thrombi to form. There is no foreign body left in the wound to cause infection.

Dr. A. Palmer Dudley of New York desired to call the attention of the members to one point. The crushing of the broad ligament prevents hemorrhage, but with this there occurs injury to the nerves and lymphatics;

he believed secondary hemorrhage occurs with as much frequency; he believed tetanus had been caused by this method, also peritonitis and infection. In the major cases he has known the rate of mortality was as great as with the ligature. There are two important reasons; when these are tied the stump can be turned in and, with a running suture, incorporated with the peritoneum. This is done by all operators and certainly the danger from the catgut can be no less when the crushing method is used to stop hemorrhage than when the ligature is applied.

Dr A. Goldspohn of Chicago believed that one ligature for the larger vessel can be used with perfect safety. He favored a sterile and very strong ligature, as the peritoneum takes care of catgut ligatures better than any other tissue in the body.

Dr J. R. Goffe of New York said that in his experience the instrument had been of great service. He has not had as many recurrent hemorrhages, and danger from infection, he considered, was reduced to the minimum.

Dr Newman, in closing, said the old methods were not perfection, and that this instrument simplified the work, a smaller ligature being used, and thus there was less danger of infection. He believed tetanus arose from the infection, not from injury, to the nerves.

Deflected Presentation in Labor.—Dr Gustav Kolischer of Chicago read a paper on the deflection necessary in face, brow, and vertex presentation. He endorsed the bimanual method for correcting faulty presentations, thereby producing occiput presentation. He adopted and endorsed the use of forceps in anterior vertex, and in brow and face presentations, and said the occiput being the lowest is the presenting part of the head.

Dr Holmes of Chicago, in discussing this paper, said that the presenting part is the vertex just anterior to the small fontanelle, and that presentation by occiput was a rare condition. He believed posture should be used in correcting these abnormal presentations, and had seen many so corrected.

Dr Kolischer in closing, strongly emphasized the point made in his paper that the occiput is the presenting part, that being the lowest. He also said that when the head is thrown backward it becomes an impossibility to bring out the child, the thorax and head producing a greater diameter than the pelvic opening.

Massage and Exercise in Management of the Puerperium.—Dr C. S. Bacon of Chicago, the writer of this paper, endorsed the principal of keeping the parturient woman in bed for two or three weeks after labor. He thought she should not be compelled to maintain a dorsal posture during that period, without movement. He did not favor the early rising. He believed the rest in bed desirable to recuperate from the exhaustion of pregnancy and labor. He believed maintenance of the horizontal position is especially necessary in patients with poor muscular development on account of the danger of ptosis of one or more of the abdominal organs. There is a great relaxation of all the ligaments, a weakness of the abdominal muscles, a faulty circulation, and abnormal secretions. The horizontal position should be maintained until return of normal circulation, as it favors proper involution of these organs. There are many objections to the bed, the muscular system becomes weakened and the circulation poor, the secretions and excretions are impaired. To overcome these objections the writer has adopted a form of massage while the patient is in bed. These exercises can be classed as passive and active. By the passive measures it becomes necessary to have a nurse or some member of the family to use every day general friction, all parts of the body should be rubbed by the dry hand. This should be repeated twice a day. The rubbing of the breasts should be done to favor the return of the circulation in the bloodvessels and lymphatics. Following this, deep manipulation of the abdominal muscles favors peristaltic movements, strengthens uterine contractions, and improves the condition of the lochial discharge. The active exercise consists in first beginning with hands by the side and flexion and extension of hand and forearm ten to fifteen times, three to four times a day. Second, swinging arm, extended at right angles to the chest. Third, extension and flexion of the feet. After the first week these motions can be made regular, every day, ten minutes at a time. After the second week more extensive movements of the thigh, leg and foot are allowable. At the end of the period of rest in bed the patient is instructed to raise the body to the upright position. These motions can be begun on the seventh day, they are useful in the interest developed in the mind of the patient. When the patient leaves the bed she is strong enough to walk about, and has not that weak feeling so often complained of.

Dr A. E. Gallant of New York said he had used the active treatment method for his patients, and found it to be of great service. He believed the patient improves much more rapidly and can be allowed to get out of bed earlier. Involution is more active, she has no syncope or weakness.

Dr Holmes of Chicago said he believed a mistake had been made in endorsing the keeping of patients in bed three to four weeks. He found the majority are able to get out of bed on the sixth day. He considered examination of tension of abdominal wall, condition of the perineum, and lastly involution of the uterus. He thought twenty-four hours long enough to keep the patient on her back.

Dr Kolischer of Chicago thought massage a good thing if intelligently done.

Dr Bacon, in closing, said that no patient should be permitted to leave her bed until the danger of prolapse of the visceral organs had passed, and that cannot be while a lax condition of the abdominal muscles remains.

Contribution to Ureteral Surgery, with Report of Four Cases, Including a New Operation for Double Uretero-Vaginal Fistula.—Dr X. O. Werder of Pittsburg, Pa., the writer, had had, in an experience of over 1500 abdominal sections, injuries to the ureters occur four times. In three of these cases there was immediate implantation into the bladder, two were successful, in the third, however, in which both ureters had become involved, there was a urinary discharge from the vagina on the fifth day, and on the sixth all the urine passed away per vaginam, the bladder remained perfectly empty. The upper portion of the vagina was subsequently made a diverticulum of the bladder, completely curing the patient.

Some Cases of Ureteral Stricture.—Dr H. A. Kelly of Baltimore read a paper in which he spoke of stricture being congenital, inflammatory, or neoplastic. For practical purposes the strictures amenable to treatment are inflammatory in nature. Ureteral strictures are due to tuberculous, gonorrheal, and other bacterial infections of the urinary tract and tissues surrounding the ureters. The forms of stricture met are thus varieties of ureteritis and periureteritis. He located the stricture by means of the catheter by which he could also demonstrate the extent of stricture. Palliative treatment consists in getting rid of the infection and providing sufficient ureteral dilatation to prevent complete or almost complete obstruction. Radical treatment consists in excision and implantation of the ureter into the bladder as well as in nephrectomy and nephro-ureterectomy.

SECTION ON MEDICINE.

Etiology of Chronic Nephritis.—Dr Arthur R. Elliott of Chicago read this paper. He said that under the name chronic nephritis are described slow inflammatory processes affecting both kidneys, due to a pathological condition of the blood and leading to destruction of the parenchyma, with eventual shrinking of the organs. The most characteristic phenomenon of this affection is not its termination in atrophy, but its casual relationship with hematic dyscrasia. As the cleansing of the blood devolves mainly upon the kidneys, it seems evident that an abnormal condition of that fluid must be the source of renal affections. It seems plain that the morbid agent, or combination of agents, is not the same in all cases. In those comparatively rare instances where chronic nephritis develops as a result of acute nephritis, the chronic lesion must be due to the same common cause as its acute precursor. This is the case in chronic nephritis subsequent to scarlatinal and puerperal nephritis. It is possible that the remaining amount of healthy renal parenchyma is not sufficient for the purification of the blood, and the products of disintegration may be in such excess as to exert a deleterious effect upon the remaining structure. The issue of acute nephritis of infectious origin in chronic nephritis is comparatively rare. The form thus originated is usually chronic tubal nephritis. Interstitial nephritis, unlike tubal nephritis, is essentially a chronic malady from the start. The majority of cases of interstitial nephritis present no signs of dropsy or other grave disturbance of health until the development of retention symptoms or evidence of cardiovascular embarrassment. It is possible that if acute nephritis lasted long enough, it might lead secondarily to a form of interstitial nephritis, but whether the disease known as chronic interstitial nephritis could result is another question. Even if acute nephritis can be established as an event in the early clinical history of a case it does not necessarily follow that prior to the attack the kidneys were sound. Simple acute nephritis in adults is so rare that it may almost be regarded as presumptive evidence that the kidney has been diseased beforehand. In cases of renal cirrhosis, apparently related with scarlatina or pregnancy, it is possible that these factors determine the renal lesion only in conjunction with accessory causes of toxic character. Renal sclerosis subsequent to arteriosclerosis is exceptional in comparison with the cases in which the vascular changes are secondary with genuine chronic nephritis as their origin. It is probable that only in rare cases of chronic indurative nephritis associated with advanced senile arteriosclerosis are we warranted in attributing a purely etiological influence to the arterial changes, the association of arterial fibrosis with renal atrophy in other cases being incidental. In any true nephritis it is the gland that is primarily affected. The common cause of all nephritis is toxic irritation of the kidney; but in chronic forms it acts more slowly, or by successive attacks. Examined in the light of our present knowledge of the actions of organic poisons, the mode of action of various determining causes of nephritis seems to be satisfactorily defined. Among these causes may be enumerated the disturbances of nutrition, such as gout, chlorosis, diabetes, syphilis, the various cachexiæ, overwork, and diseases involving certain excretory organs as chronic skin diseases, hepatic and intestinal affections. The uniformity of the action of these factors may be recognized at a glance. The urinary abnormalities under such circumstances are but symptoms of an underlying toxæmia produced by an antecedent malady. Primary interstitial nephritis is of extremely insidious development, as well as granular atrophy of the kidney; they seem to depend upon the operation of some cause very gradual and persistent in character. Certain alterations in the vascular system are an almost constant feature of the syndrome of this disease, and seem to be produced by the action of the same irritant. The speaker thought no cause so frequent and important as autotoxæmia of digestive origin. This idea is by no means a new one. While many authors have referred to autotoxæmia as a possible source of renal damage, the full extent of the relationship has, perhaps, never been stated. The success of dietetic treatment of nephritis, the importance of Dickinson's "morning purge," the effect of colonic irrigation upon renal elimination, the influence of gastrointestinal accidents in aggravating renal symptoms, etc., speak for the importance of a clean digestive tract. In chronic gastrointestinal affections an increased amount of work is imposed upon the liver with the result that the liver cells become gradually and progressively affected and eventually yield to irritation and prolonged hyperfunction, allowing the poisons which reach it from the bowel, together with the products of disturbed hepatic function, to pass on into the general circulation. Disturbances of vascular tension follow the presence of these bodies in the blood stream, and a high degree of renal irritation results from their elimination in the urine. He called special attention to the insidious action of gastrointestinal conditions resulting from chronic constipation, and the effect of the toxins thus produced upon the kidneys, the disease being often far advanced before it is even suspected. The main purpose of the speaker was to emphasize the overwhelming importance of the toxic element in the causation of all forms of nephritis and the uniformity of action of the toxic factors, whatever special form they may assume.

Malarial Nephritis, with Report of a Case.—Dr. W. Britt Burns of Memphis, Tenn., discussed some of the findings of uranalyses, with special reference to nephritis occurring in malarial cases in which the urinary symptoms cleared up under large doses of quinine. He reported a necropsy where the gross pathology showed a large and small white kidney, a beginning hypertrophic cirrhosis of the liver, splenitis, and fatty heart. The minute pathology showed pigmentation of cells and the blocking of vessels by pigment in the liver and spleen. He quoted the conclusions of Dr. Moore of Galveston, Tex., in which it was stated that nephritis was not likely to occur in a single tertian infection for a short interval, say of five days; that a doubtful tertian infection will produce a nephritis in a large proportion of cases if it runs only for a short time. The more chronic the case becomes of any infection the more likely is it to produce nephritis. Malaria of long duration, or often repeated attacks, will produce chronic renal disease, as shown by the continuous presence of albumin and casts. Æstivo-autumnal malaria probably gives the greatest percentage of cases of nephritis, 68.7 per cent. The age of the patient, height of the temperature, or specific gravity of the urine showed no relation to the presence of albumin and casts in the cases reported by Dr. Moore.

The Classification of Chronic Nephritis.—Dr. James B. Herrick of Chicago read this paper. He said that no successful attempt had been made to classify cases of chronic nephritis from the standpoint of etiology. He found no harmony in the descriptions of the various types of this disease by anatomists and pathologists, and physicians are not always able to make a clinical diagnosis that is satisfactory. Still it is important that we have some working classification, even though it be somewhat faulty and artificial. After a search through medical literature, which at first seemed very confusing on this subject, the writer found some facts which permit of arrangement into an approach to orderly grouping. First, he stated that the kidney of congestion is, by common consent, ruled out of the category of the nephritides and of Bright's disease. Virchow and others likewise exclude amyloid kidney, which is now rarely classed as a form of Bright's disease, or as an inflammation of the kidney, though it sometimes occurs as a complication of a true nephritis. There remain two distinct groups, which present such striking contrasts that one feels warranted in making of the groups separate classes. While the names used to designate these two diseases of the kidneys should be as accurate as possible in describing actual pathological conditions, it is of greater importance that the fact of the existence of these two types should be clearly recognized. To the one form, characterized by œdema and abundant albuminuria and cylindruria, the name chronic parenchymatous nephritis has been most often applied; to the other with marked cardiovascular changes, relatively slight albuminuria and cylindropsy, and an abundant flow of urine of low specific gravity, the term chronic interstitial nephritis is given. As synonyms for the former may be mentioned large white kidney, large yellow kidney, chronic desquamative and chronic tubal nephritis; for the latter, contracted kidney, granular atrophy, gouty kidney, etc. The former is the large, rather soft kidney, pale or darker, depending on the amount of fatty degeneration, with easily stripping capsule, wide cortex, and with changes chiefly in the parenchyma, the tubular and glomerular cells. The kidney of the second class is the small, rough, firm kidney, with adherent capsule, granular cut surface, thinned cortex, retention cysts, and with great increase in the connective tissue, the interstitium. While these are types frequently met with both at the bedside and on the autopsy table, great variations are not uncommonly seen. This has led to the naming of subvarieties, tending more to complication than to simplification. Parenchymatous and interstitial are in reality misnomers, for with every parenchymatous nephritis the interstitial tissue is also involved and parenchymatous changes are seen in every case of chronic interstitial nephritis. The process is in reality a chronic diffuse nephritis. In one case the parenchyma is chiefly involved and there is no induration, in the other the interstitial structure shows the primary change and there is contraction. Hence we have (1) Chronic diffuse nephritis without induration, (2) Chronic diffuse nephritis with induration. Clinically, we find many hybrid forms, and must be content with the diagnosis of chronic or chronic diffuse nephritis. It is well to have both student and practitioner realize that it is frequently impossible to make disease conform to the classical type. Different forms are combined with each other in a variety of ways. As a subhead under chronic interstitial nephritis should be placed the arteriosclerotic kidney with its striking local vascular changes. The classification that seems best is practically that of Senator. It appeals to both the clinician and the morbid anatomist. The term parenchymatous can be used in place of "diffuse without induration," though not literally expressive of the true condition it recognizes that parenchymal changes predominate. The classification would be: (1) Chronic parenchymatous nephritis (chronic diffuse nephritis without induration). (2) Chronic interstitial nephritis (chronic diffuse nephritis with induration). (a) Primary chronic interstitial nephritis. (b) Secondary chronic interstitial nephritis. (c) Arteriosclerotic kidney (arteriosclerotic interstitial nephritis). (3) Mixed type, i.e., combination of 1 and 2.

The Diagnosis of Chronic Nephritis.—Dr. ALOYSIUS O. J. KELLY read this paper. He called attention to certain pathological and clinical features of the disease, though he had nothing new to add, as we really know but little more on the subject than was known by Bright. For the differential diagnosis of albuminuria he distinguished the following forms: (1) Extrarenal, spurious, accidental, or factitious albuminuria. (2) So-called functional, physiological, or cyclic albuminuria. (3) Albuminuria without noteworthy alterations in the kidney, and (4) Albuminuria with noteworthy alterations in the kidneys. To the first class belong those cases in which the albumin in the urine is but a subsidiary factor, usually not exceeding more than 1-10 by bulk, and it is proportionate to the amount of blood and pus. A disproportionate amount of albumin should always excite a suspicion of nephritis. The presence of casts is of the greatest importance, their persistence being clear evidence of nephritis. (2) So-called functional albuminuria occurs usually in young subjects, and is usually detected accidentally. Great circumspection must be exercised in diagnosing this variety of albuminuria. The albumin should never exceed more than 0.1 per cent., the urine should contain no other abnormal constituent, every bodily organ should be examined and found to be in perfect health. A diagnosis should not be made until the patient has been long under observation and many examinations of the urine voided both morning and evening have been made. Albumin may be temporarily absent even for long periods in certain cases and at certain stages of chronic interstitial nephritis. (3) Albuminuria without noteworthy alteration in the kidney. To this class belong cases of active and passive congestion of the kidneys, cases of toxic degeneration of the kidneys, the kidney of pregnancy, amyloid degeneration of the kidney, acute and chronic suppurative and non-suppurative inflammations of the kidneys, and tumors of the kidneys. In these cases the albuminuria acquires its importance from the attendant phenomena. Hence we must make a diagnosis on this basis and not upon the amount of albumin.

The cardiovascular changes in chronic nephritis are of extreme interest and importance: they dominate the clinical picture of the disease and they assume the commanding position in the prognosis and in the treatment. The lesions are widespread, involving the heart, the large and small arteries, the capillaries and sometimes even the veins. In the majority of cases the left ventricle alone is affected; in the remainder of cases both ventricles are affected. Predominating dilatation of either or both ventricles is an unusual event until toward the termination of life. The hypertrophy of the heart occurs in all forms of nephritis, but not in all cases. It dominates the picture in interstitial nephritis. The changes in the arteries are more complex than those in the heart. In many cases the larger arteries show a loss of elasticity, in other cases more or less arteriosclerosis and atheroma, but neither is a constant feature. The medium-sized and smaller arteries almost invariably have thickened walls. In some cases both muscular hypertrophy and fibroid alteration may be observed side by side. The changes in the arteries are not distributed uniformly throughout the body. It seems that the cardiovascular alterations result from obstruction to the flow of blood in the arterioles and capillaries, and that this obstruction is provoked by the presence of some irritative metabolic products in the blood, which in health should be eliminated by the kidneys. As chronic interstitial nephritis reveals itself in different ways, the diagnosis depends upon the results of examination of the urine, and of the cardiovascular apparatus. The urine is increased in amount and specific gravity. The amount of albumin is usually slight, at times none may be found. The changes in the pulse are of great diagnostic value. In the early stages, the arteries being contracted, the pulse is small; the internal pressure being increased, the pulse is hard and resisting; the pulse waves are small, the artery remains persistently full between beats. Later there is added the evidence of arteriosclerosis, and later still the changes of atheroma. A diagnosis based upon increased arterial tension, accentuated second aortic sound, and the physical signs of hypertrophy of the left ventricle will rarely be wrong. They may be detected even in the absence of positive signs of kidney disease in the urine.

The Early Circulatory Indications of Chronic Bright's Disease.—Dr. LOUIS FAUGÈRES BISHOP of New York read this paper, in which he stated that chronic Bright's disease still remains a good clinical term for a condition involving many organs. It is no longer to be regarded as a disease essentially pertaining to the kidneys. In fact, the fatal factor is often found in the brain or the general nutrition. The kidneys and the brain act as end organs with relation to the circulation, and manifest the earliest symptoms of disorder in the small blood vessels. The earliest circulatory disturbances find their indication in the brain, which is highly sensitive to every irregularity in its blood supply.

The most characteristic early circulatory symptom of chronic Bright's disease is the development of arterial tension, and this affords first indication of the development of arterial irregularities in the circulation. Temporary unconsciousness, slight paralysis, or even evanescent aphasia may indicate the development of disease of bloodvessels, that in its full development will be typical Bright's disease.

The early recognition of these signs is important, because a proper hygiene and a proper therapy will longer delay the development of the disease.

Uræmic Aphasia.—Dr. David Riesman of Philadelphia read this paper. He offered the following conclusions: (1) Thataphasia may occur in uræmia, and is at times the sole expression of that state; (2) It is frequently associated with right-sided motor paralysis, hemiplegic or monoplegic in character: (3) It may be the precursor of uræmic convulsions or coma; (4) The aphasia is usually of the motor type, but may be sensory. There may be word-blindness and word-deafness; (5) It may be associated with agraphia, even when there is no paralysis of the limbs; (6) It is comparatively frequent in children, particularly in cases of post-scarlatinal nephritis. In adults it may occur in any form of Bright's disease; (7) It is generally transient, disappearing completely. In time it is intermittent and has a marked tendency to recur; (8) When paralysis is present, the two may disappear simultaneously, usually the aphasia first; (9) The features of uræmic aphasia are, *per se*, not characteristic of the causal condition; (10) The most important diagnostic features are the transitoriness of the aphasia and the presence of other uræmic symptoms and of signs of nephritis; (11) In every case of sudden aphasia, the possibility of its being renal in origin should be considered, and careful studies of the urine and of the system at large should be made with this thought in mind.

Endocarditis as a Complication of Pneumonia.—Dr. E. F. Wells of Chicago read this paper and offered the following conclusions: (1) Endocarditis is an infrequent occurrence in pneumonia and ulcerative endocarditis is a rare event; (2) When endocarditis occurs it does so comparatively early in the pneumonic attack, and ulceration may occur at any time within the period of probably several weeks, the time being possibly coincident with some valvular strain; (3) The symptoms and signs previous to ulceration, or in the cases in which this does not occur, are equivocal; (4) Any of the valves may be affected, but the preference is for the aortic. The vegetations are quickly formed and massive, and they have a marked tendency to ulcerate. Pneumococci are present early, and should ulceration occur the blood becomes infected. Later the pneumococci die and embolic showerings are sterile; (5) In simple endocarditis the diagnosis is always difficult and often impossible. The murmurs and embolic showerings of ulcerative endocarditis render the diagnosis of this condition easy; (6) The prognosis of simple endocarditis is not well established, but that of the ulcerative form is extremely grave, although not absolutely hopeless; (7) The treatment of pneumococcal endocarditis, both simple and ulcerative, should embrace, as a cardinal and the most important principle, absolute rest in the recumbent posture, this throwing the least possible strain upon the heart; (8) There is but little tendency toward cicatricial contraction, and when recovery ensues, even in cases with ulceration, the integrity of the valve may be unimpaired and health completely restored.

Venesection.—Dr. H. B. Favill of Chicago read this paper. He said that during the last few years there was a tendency to place a greater value upon bleeding. The indications for its use, as now defined in literature, are vague and indefinite. It is important that this procedure of recognized value be not indiscriminately employed. When the heart, for various reasons, seems incapable of disposing of the blood, which it is called upon to circulate, venesection may be of value in certain well-chosen cases. The point of importance is what conditions are in any degree amenable to correction by the withdrawal of blood? It seems, from the mechanical side, the condition of the heart muscle rather than the intensity of the provoking cause will determine the issue. He postulated that whenever we find great pulmonary embarrassment due to vascular engorgement, bleeding is indicated.

There is a symptomatic relief in a variety of conditions, a radical relief in a very limited group. It has a distinctly life-saving power in a small per cent. of appropriate cases. It may be indicated in plethora. There is small danger even in abstracting considerable blood.

The Employment of Digitalis and Aconite in the Treatment of Cardiac Diseases.—Dr. H. A. Hare of Philadelphia read this paper. He considered the importance of studying the state of the cardiac muscle in the various conditions in which evidences of circulatory failure were manifest. He emphasized the fact that, while physicans very frequently regarded the valvular lesion as the important factor in the case, the condition of the heart muscle, after all, was the most important matter to be studied by physicians, since valvular lesions in themselves were of little importance if compensatory hypertrophy existed. He also emphasized the fact that after many acute diseases the physician was wont to neglect the consideration of the heart as the important factor in the recovery of the patient. An examination of this organ might fail to reveal any signs of valvular difficulty, yet it might be so feeble in its action as to be incapable of supplying all portions of the body. It also might be enfeebled by an impoverished condition of the blood, for the heart could not be strong when poor blood was circulating through its coronary arteries. Dr. Hare also advocated the administration of small, rather than large, doses of digitalis in the treatment of most cases in which this drug was indicated, and thought that the best results were usually obtained by the continued administration of these small doses, rather than by the use of the large ones which were commonly employed. He also spoke of conditions in which aconite could be employed, alone or in conjunction with digitalis, with very excellent results. He was quite sure that in a certain number of cases of valvular heart disease the patient did not require digitalis or any other cardiac stimulant; but, on the other hand, in addition to rest, they will often be greatly benefited by the administration of aconite, which has the same steadying effect upon the heart through its influence upon the vagi as has digitalis, while by its sedative influence upon the heart muscle in cases of excessive compensaiton, and by its relaxing effect upon the blood vessels, it diminishes the over-action of hypertrophy which is sometimes confused with the tumultuous over-action of ruptured compensation.

Tuberculous Myocarditis.—Dr. J. M. Anders of Philadelphia read this paper and made the following conclusions: (1) Tuberculosis of the myocardiun is more common than has been supposed; (2) At present writing not more than three pathological varieties are justifiable; (3) It is practically always secondary to a lesion in some other situation, most commonly in the bronchial or mediastinal glands; (4) Transmission through the heart occurs most frequently by the lymph stream, less often by the blood current, and more rarely still as the result of extension by continuity; (5) Myocardial tuberculosis, in a considerable proportion of cases, is secondary to pericardial tuberculosis and the latter to disease of the bronchial glands; (6) The symptomatology is extremely variable and indefinite; (7) Diagnosis is excessively difficult, but is probably possible with great care and under favorable circumstances. In addition to the suspicious features that may be present the existence of generalized tuberculosis and pericardial tuberculosis, one or both, are essential to a diagnosis.

The Autogenous Diseases, etc.—Dr. V. C. Vaughan of Ann Arbor, Mich., read this paper, and said that we had not as yet had sufficient data to enable us to attempt even a provisional classification of the autogenous dis-

[illegible] connected with the [illegible] (1) The digestive organs may not properly perform their function, and the products of these incomplete [illegible] may be absorbed and may lead to more or less disturbance in certain organs of the body. Moreover, every part of the body may suffer more or less from [illegible] due to the fact that properly prepared [illegible] not [illegible] the [illegible] of the [illegible]. When [illegible] and [illegible] are [illegible] directly into the blood they act as powerful poisons. (2) That certain secretions and excretions of the human body act as poisons when brought in contact with tissues with which normally they have no relation, is well known. (3) It is the function of certain organs of the body to prevent the passage of certain substances into the general circulation. (4) That the undue retention of excrementitious substances frequently lead to disturbance of health is well known. (5) That certain cells in the body fail to adjust themselves to general alterations taking place in other organs at certain periods of life is quite evident. (6) Under conditions but little understood at present certain cells of the body fail to utilize certain foodstuffs. This is true in certain forms of diabetes. The cells which are accustomed to absorb and utilize the sugars find themselves unable to accomplish this duty, and the unused sugar acts as a poison to other tissues. (7) Active poisons are sometimes formed by certain cells in the body. In this way we account for the presence of certain of the more highly toxic leucomaines and some of the more poisonous acids, such as oxybutric, and some of the poisonous gases, and some of the alkaloidal bodies.

Appendicitis from a Physician's Standpoint.—Dr. JAMES TYSON of Philadelphia read this paper. He believed that the physician was too conservative in the treatment of this disease. After a thoroughly established diagnosis, operation should be recommended, even though deferred, if it can be done without danger to the patient, until acute symptoms have subsided, if they show a disposition to subside. If, however, they should not subside, operate promptly. The diagnosis is most important because operations, which have brought reproach upon the procedure, have been made upon insufficient foundation for the diagnosis.

A Case of Scurvy with Unusual Poverty of the Blood.—Dr. JAMES E. TALLEY of Philadelphia read this paper and offered the following conclusions: (1) There is no condition of the blood characteristic of scurvy. (2) Gingivitis is not a constant symptom of scurvy. (3) In certain scurvy cases there is a condition of the blood similar to that existing in pernicious anæmia, though any definite connection between the two diseases is not demonstrable. (4) The most important element in the causation of scurvy appears to be a diet lacking in vegetables or their equivalents. Tainted food may produce it, and an exclusive diet of perfectly fresh meat and bread may prevent it. (5) The infectious theory is gaining a strong foothold among the authorities, although no definite microorganisms have yet been discovered which can be regarded as pathogenic for the disease.

THIRD DAY, THURSDAY, JUNE 12.

Nomination of Officers.—The following are the names of officers proposed for election at the coming general session on Friday: *President*, Frank Billings of Chicago; *Vice-Presidents*, W. A. Witherspoon of Tennessee, G. F. Comstock of New York, C. R. Holmes of Ohio, James H. Dunn of Minnesota; *Secretary*, G. H. Simmons of Illinois; *Treasurer*, H. P. Newman of Illinois. *Orators*: Medicine, J. M. Anders of Philadelphia; Surgery, A. F. Jonas of Omaha; State Medicine, W. H. Welch of Baltimore. Little Rock, Ark., was recommended for the next place of meeting.

Surgical Suggestions.

Coley's Fluid was tried in eight cases of inoperable cancer. All the patients were kept under observation until death. The results do not justify its trial in any operable case.—ROBERT B. WILD.

Modified Finsen Method.—The lupus patient sits with his head to a window for an hour daily. The sun's rays are reflected by a mirror and concentrated by a biconvex lens. The rays pass through a solution of ammonio-sulphate of copper, which absorbs those having burning qualities.

Compound Fracture.—(1) Never apply a plaster splint to a compound fracture; (2) Treat the laceration antiseptically; (3) The writer uses the Levis metallic splint in those cases with marked wound where laceration is anterior; (4) The bandage is so applied that, while holding the bones, it does not cover the laceration; (5) It is a good rule to unbandage a fractured limb every two to five days, particularly a compound fracture, then wash and rub the limb thoroughly; (6) Ununited fracture comes more frequently from circulatory stasis than from movements of the fractured ends, then do not be so dreadfully afraid of possibly breaking adhesions when the splint is carefully removed; (7) A little massage will quickly compensate for a trifle of disturbance of the fractured ends; (8) If pus should form, use calcium sulphid and echinacea, or ichthyol, keep bowels free and apply H_2O_2, ichthyol, etc., locally; (9) Every traumatism has its medical as well as surgical aspect, that's what's the matter with the man of one idea" the surgeon; (10) Above all, call frequently upon your fracture cases, and if they want the dressings or splints altered, try to oblige them, for that is what they pay you for.—C. E. BOYNTON, *Medical World*, January, 1902.

Cocaine, when applied to the larynx or pharynx, may have its bitter taste covered with saccharine.—MORITZ.

To Remove Adherent Dressings, moisten them well with oxygenized water whose action frees the gauze.—MIKULICZ.

Trendelenburg's Operation is advocated for varicose veins of the leg. A portion of the vein is excised in the thigh to relieve the varices of the tension caused by the weight of the column of blood above them.

In fifty-seven cases, 75 per cent. were cured.—RAMSAY, *Intercolonial Journal of Australasia*, April 20.

Indications for Operation in Gastric Ulcer.—1. Acute hemorrhage should rarely be treated by operation. The results of interference have not been good, while the results of medical treatment have been satisfactory. When, however, a hemorrhage frequently repeats itself, even though not severe in amount, it will demand operative treatment as soon as its recurrent character is plain.

2. Small frequent hemorrhages, threatening anæmia, give a clear indication for operation.

3. Perforation of the stomach, either acute with general peritonitis or chronic with surrounding adhesions and perigastritis, demands instant operation.

4. When an ulcer runs a chronic course with a strong tendency to recurrence, and gradually diminishes the patient's capacity for work and the enjoyment of life, an operation is indicated, especially when the patient is so situated as to be dependent on his daily work for support, and unable closely to regulate his diet.—A. T. CABOT, *Trans. Mass. Med. Soc.*

Stab Wounds of the Heart.—G. T. Vaughan (*Virginia Medical Semi-Monthly*, March 7, 1902), states that: The time has arrived when wounds of the heart should be operated on with as little hesitation as wounds of the brain, with the expectation, under corresponding conditions, of getting equally as good results. The mortality must inevitably be high—not from the operation, but from the injury—especially if all cases, including desperate ones, be undertaken. Selection of cases who have survived five or more hours after receiving the wound would give a good percentage of recoveries, but such selection is not to be recommended, as it would be unjust discrimination against the severe cases.

In all cases of wounds in the region of the heart, with symptoms threatening life, an exploratory operation should be done by making an osteoplastic flap by dividing the fourth and fifth costal cartilages at their attachments to the sternum, the ribs about one inch external to their attachment to the cartilage, and the muscles of the fifth intercostal space, somewhat according to the method of Roberts. This flap turned up as a door on a hinge, gives a good view of the pericardium, and can easily be enlarged upward, if more room is required.

While early and speedy operation is often essential to success, yet the importance of asepsis cannot be too strongly emphasized on account of the great danger and disastrous results of pericarditis and empyema. If there has been much hemorrhage, a quantity of physiological salt solution, approximately equal in amount to the blood lost, should be injected into a vein while the surgeon is operating on the heart, if it has not been done sooner.

Strangulated Umbilical Hernia.—This is the kind of case the surgeon has learned to look on with disfavor. In the first place, such fat subjects stand no operation well where general anæsthesia is to be used. In the second place, a large, irreducible, strangulated umbilical hernia is always serious. Under no other circumstances than that of strangulation would I consider an operation in such a subject.—W. C. Dugan, *American Practitioner and News*, *September*, 15.

Treatment of Foreign Bodies in the Œsophagus.—N. Stone Scott (*The Cleveland Medical Journal*, March, 1902), says: Treatment of foreign bodies in the œsophagus will vary materially with the kind of body and complication of the case. Thus, a hard substance should be immediately removed. Nothing is gained by delay, and if allowed to remain infection and inflammation supervene and add to the difficulties of the case. When the patient is anæsthetized the foreign body can frequently be grasped by forceps or coin-catchers, and withdrawn through the mouth. If lodged as far down as the diaphragm, it can usually be pushed on into the stomach, provided there be no pathologic thickening of the esophagus at this point. Subsequent treatment of such cases will depend upon the symptoms. The patient should be allowed to recover from the anæsthetic, and if no further symptoms warranting interference supervene, nothing further should be done. The foreign body will usually pass through the pylorus and the rest of the alimentary track without difficulty. Should it become lodged lower down, operative interference may be required for its removal.

When the cause of obstruction can neither be grasped by the forceps and withdrawn, nor pushed on into the stomach, the simplest and best method of relief is by an external esophagotomy, which should be done with every surgical precaution. Even should it be possible to remove the body through the mouth, this same procedure in order to provide for drainage is advisable in cases in which the foreign body has been allowed to remain until the patient has become septic. The incision is made upon the left side at the internal border of the sternocleidomastoid, the dissection carried down to the esophagus by means of the blunt instruments rather than by cutting, the various structures being pushed to one side, the esophagus is opened with a sharp instrument by a clean cut, and the foreign body extracted with as little laceration of the tissues as possible. The incision in the esophagus should be closed with a catgut, and a strand of gauze, horsehair, or other means of drainage inserted, the external skin incision being closed thoughout most of its extent. It is a technical error to entirely close the skin incision, because the structure of the esophagus renders its sterilization impossible, and infection is liable to occur from the wound in the esophagus. An esophageal fistula is apt to result from the operation, but as a rule is of slight moment and will spontaneously close in the course of a few weeks. The after-treatment of these cases is simple. Nothing should be given by mouth for a number of hours until the first efforts at repair have been accomplished, although as a rule the patient will be able to swallow with little or no difficulty.

Surgical Hints.—In amputating fingers recollect that the joints are always in advance of the knuckles, *i. e.*, nearer than they are to the ends of the fingers.

Always shave all hairy parts before applying adhesive plasters, or else the patient will be apt to think the remedy worse than the disease.

To get a broken leg in the proper position, see that the ligamentum patella, the tubercle of the tibia, and the middle of the ankle are in a straight line.

Warts and moles may be removed by touching them daily with glacial acetic acid, which must not be permitted to touch the healthy skin. If this is carefully done no scar will be left.

Since, in modern surgery, it has been recognized that the skin is the principal source of infection, it is well, in operating, to use one knife to cut the skin and to replace it by another for the deeper work.

In operating near the female bladder, it must be remembered that the latter is never perceptible to the touch unless distended, or, better still, unless an instrument such as a sound has been passed into it.

In making incisions in the wrist and forearm, always ascertain, if possible, whether the ulnar artery, instead of running under the superficial muscles, passes over them, as is frequently enough the case.

In all emergency cases of operations in which the patient shows any evidence of bronchitis, begin the treatment of this condition at once. A good-sized dose of digitalis with one of the salts of ammonia before operating is useful.

In the shoulder, in the normal relation of the bones, and in every position, the greater tuberosity of the humerus faces in the direction of the external condyle. The head of the bone faces nearly exactly in the direction of the internal condyle.

It is never likely that gonococci are present in the female genitalia when the mucous membranes appear to be perfectly healthy; on the other hand, they may be present in any case in which an unhealthy secretion appears, however mild the latter may be.

After amputations, never wait to apply an artificial limb beyond the time when the stump is well healed and the patient is strong again. Disuse of the stump for too long a time makes it less able to stand the artificial limb. The only exception to this rule is where the operation was done for malignant disease, where early pressure and concussion might favor a return.—*International Journal of Surgery*, April, 1902.

Smallest Microbe.—According to the New York *Herald*, Mr. O. Voges of Buenos Ayres has discovered the smallest bacillus which has yet been identified. It is much smaller than the bacillus of influenza, and is only just discernible when magnified about 1,500 times.

Mr. Voges discovered these very minute rods in abscesses which afflict cattle in South America, producing a disease known as manquea. The malady generally attacks cattle while they are quite young, and is easily recognized by the characteristic lameness of one leg, which it produces. Mice, rats and rabbits are not affected by this microbe, but guinea-pigs succumb to its action in from twenty-four to forty-eight hours. Another singular fact noted by Mr. Voges is that the animals which he inoculated succumbed only when the weather was hot.

Medical Items.

Contagious Diseases Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, New York City, for the week ending June 7, 1902:

	Cases	Deaths
Measles	312	21
Diphtheria and croup	[illegible]	43
Scarlet fever	316	22
Smallpox	64	19
Varicella	78	
Tuberculosis	[illegible]	145
Typhoid fever	23	12
Cerebro-spinal meningitis	—	3

London's Latest Census.—The figures given by the "Detailed Abstract of the 1901 Census Returns for the County of London" apply exclusively to the Administrative County of London, and the persons actually within that sphere on the night of the census. London, as every one must be aware, is a name of peculiar elasticity. If we take it, for instance, to mean the municipal city of London—the "one square mile"—we find that its stationary population is only 26,923 souls. And if, on the other hand, we take it to imply so-called greater London which embraces over 400,000 acres and includes such distant suburbs as Epsom, Farnborough, Barnet and Waltham Abbey, Londoners may then boast the mighty population of over six and a half millions. Actually, however, we are concerned with London County proper, created in 1888 from parts of Middlesex, Surrey and Kent, and having an area of nearly 75,000 acres. The total population of London in this meaning is 4,536,541. In 1801 the population was just under one million; it has, therefore, increased during the century nearly five fold, but since 1851 a decline in the rate has been in steady progress. One of the most potent causes influencing this decrease in the rate of growth of population within the county area is the migration of Londoners to the suburban districts. During the past ten years the loss by migration is calculated as exceeding 180,000. This centrifugal dispersion of town population is, however, shared by all great, old and prosperous cities.

The females in London exceed the males by a quarter of a million.

The Londoners proper, native in the county, were returned as just over three millions strong. Others living in the metropolis included 60,211 Irishmen, 56,605 Scotchmen, 35,421 Welshmen, and 161,222 persons of foreign birth. Of the 135,377 foreigners not naturalized British subjects, natives of Russia are now the most numerous in London; Germany stands second; Russian Poland follows; France is fourth and Italy fifth. The Russians in London have increased since the last census from 12,034 to 38,117—fully threefold—while Italy has doubled her contribution toward the population, now accounting for a round 10,000.

Restricted Vision in Cities.—The *New York Evening Post* quotes from the *New Orleans Times-Democrat* as follows:

"Speaking of the practice of wearing glasses," said a well-known optician in Canal street, "there is a curious thing about the human eye that the average person is constantly overlooking. We talk a great deal about the influence of color, about glare and all that sort of thing. Unquestionably, color has a great deal to to with the weakness of the human eye at this time. Glare figures as an important factor in the impairment of the human sight. In the matter of color there is so much noting in these latter days that the eye is kept in an almost constant strain. Red is violently red, green violently green, and so on, until the eye is simply strained beyond the normal in an effort to compensate the hue and hence the optic nerves are, in a measure, strained and injured. But this is not the greatest danger when we come to think of the modern tendencies so far as the human eye is concerned. There are other conditions which are infinitely more injurious than the matter of color. The glare is bad enough too. The electric and incandescent lights are simply fearful on one's eyesight. But the thing I guard with more than any other influence is the condition which limits the scope of one's vision. The eye should have a broad range. One should have the opportunity of seeing a long distance. We are denied that opportunity. We are hemmed and hedged in until the distance we are capable of seeing is very short indeed. That is why I am a strong advocate of parks of promenades. Green is naturally a restful color, and if the city would be provided with long avenues and splendid parks, where one's eyes could stretch out in a long vista, it would be a great thing."

Health Reports.—The following cases of smallpox, yellow fever, cholera, and plague have been reported to the Surgeon General, U. S. Marine Hospital Service, during the week ended June 7, 1902:

		Cases	Deaths
SMALLPOX—UNITED STATES

POST-GRADUATE INSTRUCTION IN GREAT BRITAIN.

LONDON.

ALL of those facilities for post-graduate instruction in London which are open to British medical men are equally available to American graduates. The institutions which offer facilities may conveniently be divided into three groups:

I. Those which wholly or in part devote themselves to giving instruction specially designed for graduates.

II. Those general or special hospitals which have no schools, but which offer instruction and opportunities for study to graduates and senior students.

III. Those general hospitals which, having medical schools attached to them, allow qualified strangers to share the instruction and opportunities for study primarily intended for the students of their respective schools.

At many of the institutions mentioned below, it will be observed that clinical clerkships or assistantships are open to graduates and senior students.

For practice it will be found that the holders of those posts are mostly graduates, and no better means of studying the various specialties can be found than the tenure of such a post for two or three months, which includes what may be called individual tuition from members of the staff. As a rule, a clerk or assistant is attached to one physician or surgeon only, and does not follow the practice of the others, but as the medical officers attend on different days, there is nothing to prevent a graduate holding two clerkships at once if vacancies occur.

It is hardly necessary to state that at all hospitals American medical graduates will be welcomed as visitors.

I. In the first group are the following:

1. The Medical Graduates' College and Polyclinic with which nine special and general hospitals are associated.
2. The West London Hospital and Post-Graduate College.
3. The Westminster Hospital (special course).
4. The London School of Tropical Medicine.

II. In the second division are the following:

5. The Hospital for Sick Children.
6. The East London Hospital for Children.
7. The London Throat Hospital.
8. The Hospital for Diseases of the Throat.
9. The Central London Throat, Nose and Ear Hospital.
10. The Moorfields' Eye Hospital.
11. The Royal Westminster Ophthalmic Hospital.
12. Central London Ophthalmic Hospital.
13. The Chelsea Hospital for Women.
14. The Hospital for Women, Soho Square.
15. The Queen Charlotte's Lying-in Hospital.
16. The National Hospital for Epilepsy and Paralysis.
17. The Hospital for Consumption.
18. The Bethlem Royal Hospital (for the insane).
19. The Great Northern Central Hospital (general).
20. The Lock Hospital (venereal).
21. The Fever Hospitals of the Metropolitan Asylums' Board.
22. National Orthopædic Hospital.
23. The Asylum for Idiots, Earlswood.

III. In the third division are the following:

24. The Associated (nine) Metropolitan Schools of Medicine.
25. St. Bartholomew's Hospital.
26. The London Hospital.
27. The London School of Medicine for Women (Royal Free Hospital).

I. The Medical Graduates' College and Polyclinic is by far the most important institution for post-graduate teaching in the United Kingdom. Its headquarters, at 22 Chenies street, W. C., are in a specially constructed building, which contains a museum in which are Mr. Jonathan Hutchinson's great collection of drawings of disease, and a library containing his collection of original articles by many authors, ingeniously arranged to facilitate references, and most valuable to workers who desire to get at the bibliography of any subject. There are also lecture rooms, laboratories, ophthalmoscopic dark rooms, *x*-ray installation, and smoking and reading rooms. The college is centrally situated, on the western border of Bloomsbury, about midway between the Tottenham Court Road Station of the Central London Electric Railway ("The Tube") and the Gower Street Station of the Metropolitan Railway. There are good hotels and lodgings at a moderate price in the neighborhood. The membership fee is one guinea (£1 1s—$5.)

American medical men are always welcome, and are given a complimentary ticket free, which is available for three days. This enables them to see for themselves, before becoming members, the advantages offered by the college. The following are the advantages offered by the Medical Graduates' College and Polyclinic to its members: (1) They can at any time send up or bring patients for consultation (on the understanding that the case is one suitable for gratuitous advice). (2) They can attend all consultations and clinical lectures. The consultations take place from 4 to 5 o'clock every afternoon, except Saturday, and the clinical lectures usually at 5 o'clock. (3) They have access at all suitable hours to the library, the reading room and the clinical museum. (4) They receive the Journal. It is published monthly and contains, with much other clinical matter, a record of the lectures and of the more important consultation cases, and a "Companion-Catalogue to the Museum." (5) They have access under certain conditions to the pathological laboratory, and can also obtain analyses and examinations of specimens.

Cliniques are held daily at 4 o'clock, on cases of interest, as follows.

Mondays, Skin; Tuesdays, Medical; Wednesdays, Surgical: Thursdays, Mr. Jonathan Hutchinson's Surgical. Fridays, Eye, Throat and Nose.

Clinical lectures are given on alternate Wednesdays at 5.15 P.M.

Short courses of didactic lectures on special subjects are delivered every month. The laboratory is open for private research to members upon terms which can be ascertained on inquiry, and analyses are undertaken and reports furnished upon pathological specimens submitted for examination.

These cliniques and clinical lectures go on throughout the whole year, with the exception of the month of August, during which the college is closed.

Four sessions of practical classes of six weeks' duration and a vacation term of three weeks are held during the year. The following are the subjects:

The Anatomy and Physical Diagnosis of the Chest and Abdomen, Tuesdays and Thursdays at 6 P.M., begins April 14. Dr. J. E. Squire and Mr. A. Carless.

Clinical Examination of the Nervous System, Fridays, from 2 to 3.30 P.M.; begins April 18. Dr. Harry Campbell.

Practical Application of the Röntgen Rays, Thursdays at 3 P.M., begins April 17. Dr. Harrison Low.

Practical Ophthalmology, the use of the Ophthalmoscope and Refraction, Fridays, from 5 to 7 P.M., begins April 18. Mr. L. Vernon Cargill.

Practical Rhinology and Laryngology, Wednesdays, from 5 to 7 P.M.; begins April 16. Dr. W. Jobson Horne.

Practical Otology, Mondays, from 5 to 7 P.M.; begins April 14. Mr. R. Lake.

Clinical Microscopy, Mondays and Wednesdays, from 2 to 3.30 P.M.; begins April 14. Mr. Hayward Pinch.

Fee for each class, £1 1s.; composition fee for all seven classes, £5 5s.

Extra mural classes in association with the college are held on the following subjects: Practical Bacteriology, daily from 10 A.M. to 4 P.M., Professor Tanner Hewlett. Fee, £5 5s. for one month; £8 8s. for two months. Hygiene and Public Health, Dr. Wynter Blyth. Fee, £2 2s. Mental Diseases, Dr. Maurice Craig. Fee, £1 1s. Operative Surgery, Mr. W. Johnson Smith. Fee, £4 4s.

Extra classes in any subject will be formed to suit the convenience of practitioners unable to attend those already provided.

Mr. Jonathan Hutchinson conducts a clinique every Thursday, and among the lecturers are the following well-known names: Dr. Mott (Pathology of the Insane); Sir John Batty Tuke, Mr. Bland Sutton, Dr. Theodore Williams, Sir Anderson Critchett, Mr. Howard Marsh, Dr. Hale White, Dr. William Hunter, Dr. Dundas Grant, etc. Consultations on cases sent up by members are held from 4 to 5 P.M. on five days a week.

In addition to the instruction given at the college and in the extra mural classes, arrangements have been made under which members, on payment of small additional fees, receive clinical instruction at the following nine institutions: Blackfriars Hospital for Diseases of the Skin, *Seamen's Hospital, Greenwich; *East London Hospital for Children; *Evelina Hospital for Sick Children; *North London Hospital for Consumption (out-patient department only, 41 Fitzroy Square, W.); Throat Hospital, Golden Square; *Seamen's Hospital, Victoria and Albert Docks Branch, Greenwich, Westminster Ophthalmic Hospital; and *North West London Hospital. The fee is one guinea per month per hospital, or a composition fee of £5 5s. will admit for two months to the practice of all of the six hospitals above marked with an asterisk.†

Lectures are also given at Bethlem Royal Hospital for Lunatics. Schedules of cliniques and lectures and of hours of instruction in the associated hospitals may be obtained from the medical superintendent, Captain A. E. Hayward Pinch, F.R.C.S., at the college, 22 Chenies street, London, W. C.

2. The West London Post-Graduate College is attached to the hospital of that name in the western borough of Hammersmith, four miles from Charing Cross and six miles from the Bank (i. e. the center of the "City").

The following extracts from its prospectus fairly set forth the advantages it offers:

The West London Hospital was founded in the year 1856, and incorporated by royal charter in March, 1894. It contains accommodation for 175 beds, of which 150 are in daily occupation. 2,500 in-patients were treated in the hospital during 1900, and in the out-patient department over 30,000 new patients are seen annually. Post-graduate instruction has been given at the hospital since the year 1893, and 275 medical men from all parts of the world have attended the classes. The West London Hospital is the only hospital where the practice is reserved for qualified men, and the college is the only institution of the kind in London which is attached to a general hospital. The hospital is in the main road about three miles from Hyde Park Corner; it is within two minutes' walk of the Hammersmith Stations of the Metropolitan, the District, and the South-western Railways; it is within ten minutes' walk of Kensington (Addison Road) Station, and within twelve minutes' walk of the Shepherd's Bush Station of the Central London Railway, and omnibuses pass the door from Liverpool Street, King's Cross, Charing Cross, Piccadilly, Barnes, Chiswick, etc. The physicians and surgeons attend daily, except Saturdays, at 2.30 P.M. Post-graduates accompany the staff on their visits to the wards. Instruction is given in the out-patient department daily at 2.15 P.M. by the assistant physicians and assistant surgeons. The out-patient department has recently been enlarged and there is now ample accommodation for post-graduates to see and examine the patients. There are special departments for diseases of the eye, the ear, throat, and nose, the skin, for diseases of women, and for orthopedic surgery and for x-ray work. Clinical assistants are appointed from among the post-graduates on application to the medical officer in charge. Operations are performed on Mondays, Tuesdays, Wednesdays, Fridays, and Saturdays, at 2.30 P.M., and on Thursdays at 3.30 P.M. Post-graduates are allowed to stand close to the table and can see the operations perfectly. The surgeons often avail themselves of the assistance of post-graduates at operations. Gentlemen willing to assist should signify their wish to the operating surgeon. No junior students are admitted to the practice of the hospital, and it is practically reserved for graduates, but occasionally senior students are admitted as clinical clerks and dressers.

The fee for hospital practice, including all the ordinary demonstrations, lectures, and attendance in the special departments, is £2 2s. for fourteen days; £3 3s. for six weeks; £5 5s. for three months; £8 8s. for six months; £10 10s. for one year; and £21 for a life ticket. If it is wished to pay the fee by instalments, the price of the six months' ticket will be £9 9s., payable by three instalments of £3 3s., the first to be paid on joining, the second six weeks later, and the third at the end of three months. The fee for a yearly ticket will be £12 12s., payable by four instalments of £3 3s., the first to be paid on joining, the second at the end of six weeks, and the others at intervals of three months. The fee for a life ticket will be £23 2s., payable by six instalments of three guineas, and two of £2 2s., the first instalment to be paid on joining and the remainder at intervals of three months. A course of attendance in medicine or surgery alone, or in any oné special department, may be taken out for the fee of £2 2s. for six weeks, or £3 3s. for three months.

---

† Very recently the scheme of this institution has been greatly extended. Other teaching institutions have been invited to join, and it is believed that by the autumn the clinical resources of the following special hospitals will also be available: The Great Ormond Street Hospital for Sick Children, the Brompton Hospital for Diseases of the Chest, the Queen Square National Hospital for the Paralyzed and Epileptic, and the Royal London Ophthalmic Hospital, City Road (late Moorfields).

Details as to hours of attendance or any further information may be obtained on application to Mr. L. A. Bidwell, F.K.C.S., the Dean of the College. Telephone, No. 82, Hammersmith.

3. **The Westminster Hospital** (see also Associate Metropolitan Schools of Medicine).—At this general hospital a course of ten post-graduate clinical demonstrations has been arranged for the summer of 1902, beginning on May 13, and to be held on every Tuesday at 4.30 P.M. The subjects will be as follows: Medical and Surgical Cases, Tuberculides of the Skin (May 27), and Gynæcological and Aural Cases. Drs. Allchin, Colcott Fox, Wills, Rivers, Pollock, Murrell, and Hebb, and Messrs. W. Turner, Spencer, Paton, and de Santi will give the demonstrations. The fee for the course is £1 1s., but holders of the ticket of the Associated Metropolitan Schools of Medicine (*vide infra*) are admitted without further payment.

This hospital is in Broad Sanctuary, S. W., opposite the Western Towers of the Abbey, and easily accessible. Applications should be made to Dr. Purves Stewart, 7 Harley Street, W., or to W. Wm. Turner, 53 Queen Anne Street, W.

4. **The London School of Tropical Medicine** owes its origin to the Right Hon. Joseph Chamberlain, Colonial Secretary, who, with the object of affording instruction in tropical medicine to officers in the colonial service, invited the committee of management of the Seamen's Hospital Society to establish a school in connection with their hospital.

The school was opened in October, 1899, and its advantages were offered to all medical graduates who wished to acquire special knowledge of tropical diseases. During the first two years of its existence some 170 graduates have passed through it, including several Americans.

It is located in a special building in connection with the Branch Hospital of the Seamen's Hospital Society at the Victoria and Albert Docks. This situation offers great advantages to such a school, as the hospital contains fifty beds, and to it all cases of disease occurring among the crews of the many vessels frequenting the great docks of London naturally find their way; for practically no other hospital or dispensary is available, except those of the Seamen's Hospital Society at Greenwich, Gravesend and East India Docks, which are feeders as regard tropical diseases of this branch. The nearest independent general hospital is the London Hospital, Whitechapel, which is distant over four miles. The hospital is also associated with the London Polyclinic. The school is about five and a half miles eastward from The Bank, City, E. C., and close to the Connaught Road Station, which is reached in twenty minutes by frequent trains from Fenchurch Street. A more central position would have been convenient for students, but as the committee points out it would have been difficult to secure clinical material, as Negroes, Lascars, Chinese, and Malays object to go far from their ships.

The appliances in the school are of the most modern character, the laboratories being fitted with every requisite, and the constant attendance of the medical tutor (Dr. C. W. Daniels of the British Guiana Medical Service), ensuring that all special diseases are demonstrated and investigated as opportunity arises. Bacteriology and animal parasitology are systematically taught. Pathological anatomy is demonstrated in the museum and in the post-mortem room, as opportunity may offer; the most approved methods of mounting microscopical preparations and of collecting, preserving and transmitting important vegetable or animal specimens are dealt with practically.

The following is a list of the cases of the more important tropical diseases admitted to the hospital during the two years ending October, 1901: acute malaria, 84; chronic malaria, 7; dysentery, 62; beriberi, 43; liver abscess, 11; leprosy, 4; guinea worm, 10; filariasis, 6; blackwater fever, 2; plague, 6; Malta fever, 5; hepatitis, 6; bilharzia, 1. Total, 247.

Students must be qualified medical practitioners, or be in the fifth year of their medical studies. (As a rule all are graduates). They can be provided with board and residence or partial board at the school, at moderate prices.

The hours of work are as follows: 10 to 11 A.M., ward work with note-taking; 11 A.M. to 1 P.M., systematic instruction by the medical superintendent; 2 to 4 P.M., pathological work, clinical instruction in the wards and out-patient department; 4 to 5 P.M., lectures on pathological work.

The lecturers are: Drs. Patrick Manson, Tanner Hewlett, Andrew Duncan, Oswald Baker, W. J. Simpson, Sambon, and Galloway, and Messrs. Cantlie and Treacher Collins.

There are three sessions yearly of three months each, viz., from October 1 to December 31; from January 15 to April 14; and from May 1 to July 31.

The fees payable are: for a session of three months, £16 16s.; for a course of eight weeks, £11 11s.; for shorter periods special rates are charged, particulars of which may be obtained on application.

Students who have completed the curriculum and passed a satisfactory examination will receive certificates to that effect. Students have the privilege of attending the medical and surgical practice at the Dreadnought Hospital (for seamen) at Greenwich (also associated with the London Polyclinic). This hospital contains 225 beds.

The following hospitals are in the second group:

5. **The Hospital for Sick Children,** Great Ormonde street, Bloomsbury, W. C.—This is the largest of the children's hospitals. It contains 244 beds. It is centrally located and easily reached by omnibus or rail. Nearest "Tube" station, British Museum; Metropolitan Railway, Gower street. Lectures by members of the staff are delivered every Thursday at 4 P.M. They are free to graduates. The fees for attendance on the practice of the hospital are: For three months, £2 2s.; for a perpetual ticket, £3 3s. Applications should be addressed to the secretary at the hospital.

6. **The East London Hospital for Children** (107 beds), Glamis Road, Shadwell, E.—The hospital is within five minutes' walk of the Shadwell Stations, and there are frequent trains from Fenchurch

street, Liverpool street, and all stations on the Metropolitan and Metropolitan District Railways. Four minutes' journey from Liverpool street and twenty-three minutes from Charing Cross (District). A certain number of clinical clerks and dressers are appointed every three months, both in the in-patient and out-patient departments. As the number of out-patients is very large, there is plenty of material for study, and a clerkship offers an excellent opportunity of learning pediatrics. The hospital is connected with the Polyclinic [illegible]. A clinical lecture is given every week by a member of the staff of the hospital. These lectures are open to all gentlemen who are attending the hospital practice. Fees for three months' admission to the whole practice of the hospital and including a clerkship or dressership, £2 2s.; attendance for one month, £1 1s.; attendance for six months, £3 3s.; perpetual composition fee, £4 4s. Applications should be made to the Dean, Mr H. Betham Robinson, 1 Upper Wimpole street, W.

7. **The London Throat Hospital,** 204 Great Portland street, W.—Nearest station, Portland Road on the Metropolitan Railway, three minutes' walk; Oxford Circus on the "Tube," ten minutes. Several lines of omnibuses pass the door. Clinical demonstrations on diseases of the throat, nose and ear are given daily by members of the staff, at 2 P.M., and on Tuesday and Friday evenings at 6 P.M. Operations daily at 9.30 A.M. Clinical assistants are appointed for periods of three months. Fees: one month's attendance, £1 1s.; three months' attendance, £2 2s.; perpetual ticket, £5 5s. Special post-graduate courses of demonstrations are held during the summer and winter and advertised in the medical journals. Applications should be made to Dr E. Furniss Potter at the hospital, or at 49 Queen Anne street, Cavendish square, W.

8. **The Hospital for Diseases of the Throat,** Golden square, W. This hospital is close to Regent street and Piccadilly, nearest "Tube" Station, Oxford Circus, five minutes' walk. Metropolitan District Railway, Charing Cross Station, three-quarters mile. Omnibuses to Piccadilly Circus. Forty beds. 50,000 out-patients yearly. This hospital is associated with the Polyclinic. Junior and senior clinical assistants are appointed. Considerable responsibility falls on the latter. Minor operations daily, except on Mondays, at 9 A.M. Clinical instruction is given daily in the out-patient department from 2.30 to 5 P.M., and on Tuesdays and Fridays from 7 to 10 P.M. Systematic courses of lectures with clinical and pathological demonstrations are given in the winter session. The fee is one guinea, but they are free to graduates who attend the practice of the hospital. Fees for the practice of the hospital: Three months, £3 3s.; six months, £5 5s.; perpetual ticket, £7 7s.

9. **Central London Throat, Nose and Ear Hospital,** Grays Inn Road, W. C.—One and one-half miles from Charing Cross; nearest stations, Kings Cross (Metropolitan & G. N. R. Stations) and Chancery Lane (on the "Tube"). Omnibuses pass the door. Lectures are given in the winter session. Fees for regular attendance on the practice: Three months, £3 3s.; six months, £5 5s. Two clinical assistants to each surgeon are appointed from among gentlemen paying five guineas, but they must guarantee to hold office for six months at least.

A certificate is granted to clinical assistants on completion of their period of office if they have diligently attended to their duties.

10. **Royal London Ophthalmic Hospital** (Moorfields Eye Hospital), City Road, E. C.—Located one mile to the north of the Bank. Nearest station, "Old Street" on the City & South London Railway ("Tube"). Omnibuses and tramcars pass the door. This is the chief eye hospital of the United Kingdom, and as "Moorfields Hospital" has had a world-wide reputation. It has lately been moved to the present new building. It has 125 beds. Out-patients number about 35,000 yearly, or 100 a day. The year is divided into three sessions of about three months each, beginning in October, January, and May. A course of lectures and demonstrations is delivered each session by the staff on the following subjects:

I. The Use of the Ophthalmoscope. By the Staff. This class will be limited in number. Tuesdays and Thursdays at 7.30 P.M., fee, £2 2s.

II. Errors of Refraction. By Mr Lang. Mondays at 8 P.M., fee, £1 1s.

III. External Diseases of the Eye. By Mr Morton and Mr. Holmes Spicer. Wednesdays and Fridays at 1 P.M., fee, £1 1s.

IV. Surgical Anatomy of the Eye. By Mr Treacher Collins. Three lectures and lantern-slide demonstrations at 8 P.M., fee, £1 1s.

V. A Class of Operative Surgery. By Mr Percy Flemming. Thursdays at 2.30 P.M., fee, £4 4s.

VI. Tutorial Classes are held from time to time by the assistant surgeons to give instructions in the various methods employed in the examination of cases; fee, £1 1s.

VII. Classes for x-ray work are held from time to time, fee, £2 2s. Occasional clinical lectures are given by members of the staff. Practical instruction in the pathology of the eye is given by the curator in the museum. The accommodation in the laboratory is limited. Fee for one month, £1 1s.

Perpetual students of the hospital are admitted to one course of lectures (except those on operative surgery) free. The fee for a perpetual student is £3 5s.; for six months' practice the fee is £3 3s.

American medical graduates are eligible for junior assistantships in the out-patient department and must serve for six months.

Clinical assistants must hold a diploma recognized by the College of Physicians of London or the College of Surgeons of England and serve for one year, and after two years' service are eligible as chief clinical assistants. Applications should be made to the Dean, W. Holmes Spicer, who can be seen at the hospital on Wednesday mornings.

11. **The Royal Westminster Ophthalmic Hospital,** King William street, Strand, W. C.—Nearest station, Charing Cross, within five minutes' walk. Omnibuses in the Strand less than a furlong away. This hospital is associated with the Polyclinic. The teaching at this hospital is specially arranged to meet the requirements of advanced students and qualified men.

Patients are seen, and operations performed every afternoon, at 1 P.M.; two members of the staff being in attendance every day. The clinical material is abundant; besides the ordinary clinical teaching, during the regular work of the hospital, special clinical demonstrations are held on selected cases at a fixed hour. Once a month a clinical evening is held, at which a large number of ophthalmoscopic cases are shown.

A course of lectures is held on diseases of the fundus, illustrated by lantern slides. The remaining classes are more in the nature of practical demonstrations, and are confined to a limited number of men. They are as follows:

Instruction in the use of the ophthalmoscope, the principle of the instrument is explained and the members of the class practice its use upon the artificial eye, and upon living eyes till they can use the instrument with ease.

Ophthalmoscope demonstrations on selected fundus cases, limited to a small number of gentlemen, who must be able to use the ophthalmoscope.

Practical Testing of Refraction.—This course consists in an exposition of the physics of refraction, and in practically estimating the refraction by the various tests in selected cases.

The following classes will be commenced at 4.30 P.M. on the dates given·

Mr. Hartridge—Mondays, Refraction, May 26. Mr. Adams Frost—Tuesdays, Lantern Lectures on the Fundus, May 27. Mr. Dodd—Wednesdays, Clinical Demonstrations, May 28. Mr. Roll—Fridays, Ophthalmoscope, May 30. Mr. Grimsdale—Operation Class (fee, £1 1s.), time by arrangement. Clinical Evening—The first Tuesday in each month. Patients are seen and clinical instruction is given daily from 1 P.M. Gentlemen wishing to join should send their names to the Hon. Sec., Mr. Adams Frost. Inclusive fee (except Operation Class) for six months, £3 3s. Perpetual, £5 5s., or the classes may be taken separately.

12. **Central London Ophthalmic Hospital,** Gray's Inn Road, W. C.—Nearest stations, see No. 9. This hospital has twenty-eight beds. Out-patient attendances, 30,000 yearly. Clinical assistants are appointed for three months at a fee of £2 2s.; for six months, £3 3s. A class of instruction in the use of the ophthalmoscope with demonstrations on cases are held weekly at 8 P.M., and also a weekly class on refraction with practical demonstrations at 5 P.M. The fee for each course is £1 1s., but they are free to clinical assistants.

13. **The Chelsea Hospital for Women** (fifty-two beds), Fulham Road, S. W., two and one-half miles S. W. of Charing Cross.—Nearest station, South Kensington (District Railway). Five minutes' walk; omnibuses pass the door. Clinical assistants are appointed for three months. They must attend at least twice weekly at 2.15 P.M. They must be graduates. They are eligible to receive a certificate at the end of their term of office, provided their attendances have been regular. Fee, £8 8s.

14. **The Hospital for Women,** Soho Square, W. C.—Nearest station, Tottenham Court Road "Tube," three minutes' walk. Omnibuses in Oxford street and Charing Cross Road close by. Clinical assistantships are open to graduates only. Each assistant attends twice a week in the out-patient department, the number attending each day being limited to three. The fees are, for one month, £3 3s., or for three months, £8 8s. Application should be made to the dean, Dr. Bedford Fenwick, at 20 Upper Wimpole street, W.

15. **Queen Charlotte's Lying-in Hospital,** Marybone Road, N. W., about two miles N. W. of Charing Cross—Nearest stations, Edgware Road (Metropolitan), two minutes' walk; Marble Arch "Tube," ten minutes' walk. Fifty-six beds. This hospital is the chief maternity hospital of London, and the only one at which male students and practitioners are received. The rules for students differ from those for graduates, but all are strict, in order to avoid risk of infection. Graduates must be prepared to devote their whole time to their work at the hospital and are, of course, not allowed to attend necropsies or any cases medical or surgical, outside the hospital. Fee for four weeks, £8 8s. There is a new residence for students opposite to the hospital. Terms, £1 15s. per week, including board and attendance. Applications should be made to the secretary.

16. **National Hospital for the Paralyzed and Epileptic,** Queen Square, Bloomsbury, W. C.—About one mile to the north of Charing Cross. Stations as for No. 5. Two hundred beds. This is a most important hospital with a very distinguished staff, including Drs. Bastian, Ormerod, Ferrier, and Gowers, Taylor, Risien, Russell, Beevor and Tooth, and Messrs. Victor Horsley and Ballance. Drs. Hughlings Jackson and Buzzard are consulting physicians and do not now teach at the hospital. The out-patient practice is open without fee from 2 P.M., on Mondays, Tuesdays, Wednesdays, and Fridays.

The in-patient practice is open to those who hold in-patient clerkships, and practitioners may on certain days accompany some of the physicians and be present at surgical operations.

Clinical clerks of physicians to out-patients are appointed for three months, and in-patient clerks are appointed to each physician for three months.

Three courses of lectures and clinical demonstrations are given in each year, *viz.*: winter course, October, November and December; spring course, January, February and March; summer course, May, June and July.

A clinical lecture or demonstration will be given weekly in the theatre on Tuesdays at 3.30 P.M. Surgical operations at 9 A.M., on Tuesdays, by Mr. Victor Horsley and Mr. Ballance.

The museum is available for the prosecution of special work under the pathologist, for which a separate fee is charged. The out-patient hospital practice and lectures are free, but for in-patient clerkships a fee of £2 2s., for three months, or £3 3s., for six months, is charged, or £5 5s., for life. Applications should be addressed to the dean of the medical school, at the hospital.

17. **Hospital for Consumption and Diseases of the Chest,** Fulham Road, Brompton, S. W. Stations, etc., as for No. 13 (321 beds).—This is the chief chest hospital in London. Three courses of lectures and demonstrations are given yearly at 4 P.M., on Wednesdays, as follows: spring course, January to March; summer course, May to July; winter course, October to December.

These lectures are open to graduates on presentation of their cards.

A clinical assistant in the out-patient department is appointed to each assistant physician. Attendance, twice a week at noon.

Clinical clerks are appointed to each physician to in-patients. Attendance in the wards is required twice a week from 10 A.M. to 12.30 P.M., and in the afternoon during the physician's visits. These appointments are tenable for three or six months, and are only open to graduates or students in their fifth year. Appointments are made in January, April, July, and October. The fee for the practice of the hospital is £1 1s. per month, or £2 2s. for each period of three months, or a perpetual fee of £5 5s. may be paid. Clinical assistants and clerks must enter for the practice of the hospital.

18. **Bethlem Royal Hospital for Lunatics,** St. George's Field, Lambeth, S. E. On the Surrey side of the Thames, about one mile from Charing Cross—nearest station, Elephant and Castle (South London "Tube"); omnibus from Charing Cross and tramcars from Westminster Bridge, 300 beds. This celebrated institution, notorious in the literature of the English tongue as "Bedlam," was founded in 1247 A.D., incorporated by Henry VIII. in 1547, and removed from London Wall to its present site in 1815. Lectures are given to classes from the Polyclinic from time to time. Clinical demonstrations are also given twice a week to gentlemen attending

the practice of the hospital. Fee for the practice, three months, £3 3s.

19. **Great Northern Central Hospital,** Holloway Road, N.—About four miles north of Charing Cross. Ten minutes' walk from Finsbury Park and Holloway Road Stations (G. N. Ry.), and from Upper Holloway Station (Midland). Omnibuses pass the doors. This is a general hospital of modern construction (1888) and has 130 beds. There are the usual special departments. The pathologist delivers a course of lectures yearly. Graduates may, on the recommendation of a member of the staff, be appointed clinical assistants to out-patients for six months without payment of fees. Only two graduates are allowed to each physician or surgeon.

Clinical clerks in the various departments are appointed for three months either in the in- or out-patient departments. Pathological clerks are appointed for a like period. Fees, £3 3s. for three months and £1 1s. for each additional three months' teaching. Applications to P. T. H. Beale, Esq., F.R.C.S., honorable secretary to the medical committee, 61 Grosvenor street, W.

20. **The Lock Hospital,** Dean Street, Soho, W.—For location see No. 11. For venereal diseases. Pupils are appointed either graduates or senior students. Applications should be made to the secretary, London Lock Hospital, Harrow Road, W.

21. **The Metropolitan Asylums Board.**—The fever hospitals under this board, which are supported by the rates, *i. e.* municipal taxation, will be made available for instruction of senior students and practitioners on and after May 2, 1902. The board is pleased to afford facilities for post-graduate instruction to American medical graduates. The hospitals are located in the outer zone of the metropolis, and are ten in number, containing a total of 4,500 beds. The classes at four of the hospitals are already full. The next course will begin in October, 1902. Classes are held on two or three days a week. Fees, £3 3s. for a two months' course, or £4 4s. for a three months' course. There are stringent rules as to disinfection, and brown holland suits and caps are provided and must be worn in the hospitals. Applications for further particulars should be addressed to the clerk of the Metropolitan Asylums Board, Victoria Embankment, E. C.

22. **National Orthopædic Hospital,** 234 Great Portland street, W.—For situation, etc., see No. 7. Sixty beds. Clinical instruction is given by the surgeons, and occasional lectures are delivered. Fee for the hospital practice for one month, £1 1s.; for three months, £2 2s. Application shall be made to the secretary of the medical board.

23. **Asylum for Idiots,** Earlswood, near Red Hill, Surrey.—Trains fom Victoria and London Bridge stations, about forty-five minutes' journey, 600 beds. American graduates are invited to visit and inspect the institution. The medical superintendent will be happy to afford opportunities for clinical study on application to him at the asylum. Classes from some of the London medical schools visit the asylum. London office, 36 King William street, E. C.

In the third group are the great general hospitals to which complete medical schools are attached. These are thirteen in number, including the Royal Free Hospital and the attached Women's School. All of these hospitals have special departments for eye, throat, ear, skin, gynecology, and dentistry, and some have also electrical and orthopedic departments. The amount of clinical material is very great, especially in the out-patient departments, but in the special departments the teachers are not all specialists, and the value of the instruction is often less than of that to be obtained in special hospitals. The size of the classes also in many cases detracts from the advantages offered to graduates who have to mix with the regular students of the school.

24. **The Metropolitan Schools of Medicine.**—Of these hospitals nine are associated together for post-graduate instruction under the title of "The Metropolitan Schools of Medicine," having a central office. Address: "West Wing, Examination Hall, Victoria Embankment, W. C." This is in the building belonging to the conjoint board of the Royal College of Physicians and Royal College of Surgeons, used for examinations and lecture purposes. It is close to the Strand and Waterloo Bridge, and less than half a mile east of Charing Cross. Of the above nine hospitals the Westminster alone (see No. 31) has special post-graduate demonstration classes outside the association. Fees.—For three months, £7 7s.; for six months, £10 10s.; and any longer period at the further rate of £5 5s. for each additional six months. These cards admit the holders to any part of the clinical instruction of the hospitals concerned which is open to their ordinary pupils. This association includes nine out of the twelve medical schools of London, viz., those attached to the following hospitals: Charing Cross, 180 beds, central district; Guys, 690 beds, southeastern district; Kings College, 221 beds, central district; Middlesex, 330 beds, central district; St. George's, 356 beds, western district; St. Mary's, 281 beds, northwestern district; St. Thomas's, 572 beds, southern district; University College, 185 beds, northern district; Westminster, 215 beds, southern district. The districts noted are not postal districts, but denote parts of Central London. A general time table of the arrangements is furnished with each admission card. A list of operations to be performed at the hospitals can be seen daily at the secretary's office, which is close to the Strand. Applications to the honorable secretary as above.

25. **St. Bartholomew's Hospital,** Smithfield, E. C.—Nearest stations, Farringdon street (Metropolitan R.) and Post-office ("Tube"); omnibuses to Giltspur street, Holborn Viaduct, 674 beds. This is the oldest and wealthiest, indeed the only wealthy hospital in London. Like the associated schools, it offers no special teaching for graduates, but allows them the run of the clinical side of the hospital for £15 15s. a year, or £7 7s. for three months. There are electrical and orthopedic departments here. The school has the largest number of students of any in London, which is a drawback from a post-graduate standpoint. Applications to be made to the warden, St. Bartholomew's Hospital, E. C.

26. **The London Hospital,** Mile End, E.—Three miles east of Charing Cross, one and a quarter miles east of the Bank Stations, Whitechapel (Metropolitan District R.), opposite the hospital. Trams and omnibuses pass the door, 800 beds. This is the largest general hospital, and offers an unequaled wealth of clinical material. In 1901 it treated 12,746 in-patients and 161,762 out-patients. It contains special wards for Hebrews—who abound in the neighborhood—where "kosher" food, etc., only is given; also children's wards. Maternity wards are about to be opened. There is also a very complete installation for the Finsen light treatment of lupus, etc. American graduates are eligible for three months' clinical clerkship or dressership and twelve months surgical and medical practice for the fee of £10 10s. Attendance on lectures will be free unless certificates of attendance are required. An additional clinical clerkship or dressership for three months may be had on payment of five guineas.

Applications to the warden, London Hospital Medical College, Turner street, Mile End, E. The hospital will well repay a visit.

27. **London School of Medicine for Women.**—Royal Free Hospital, Gray's Inn Road, E. C. (For stations, etc., see No. 9); 170 beds. Ladies who are medical graduates can occasionally be admitted to attend hospital practice without holding a post, when the accommodation will permit, and must pay the registration and hospital fees. Fees, registration, £2 2s.; hospital, three months, £6 6s.; six months, £10; one year, £15 5s. Special classes by permission of Vice-Dean. Applications, "accompanied by a personal reference" to the Vice-Dean, Miss Cock, M.D., or to the honorable secretary, Miss Douie, M.B., M.A.

The Hotel Accommodation in London has been much improved and increased of late years. Besides the great hotels of the first class, such as the Cecil, Savoy, Victoria, Grand, Metropole, Carlton, etc., around Charing Cross, and less pretentious large hotels, such as The Langham, Great Central (Marylebone), Russell (Russell Square), Grosvenor (Buckingham Palace Road), First Avenue (Holborn), Midland (St. Pancras), there are a number of smaller hotels of modern construction and moderate charges in the neighborhood of the Strand and Bloomsbury. Some of these are Temple Howard, Arundel, and Londoun hotels, all on the Victoria Embankment; Horrex's (Norfolk street and Strand); and several good temperance hotels, viz., the Kingsley (Hart street), Thackeray (Great Russell street), Esmond (Montague street), West Central (Southampton Row), all four in Bloomsbury. Boarding houses and lodgings are abundant in all parts of London. The advertisement pages of the daily papers, and the secretaries of hospitals, will afford full information of these.

In addition to the facilities stated above, courses of lectures are delivered each spring at the Royal College of Physicians, Pall Mall (corner of Trafalgar Square), and at the Royal College of Surgeons, Lincoln's Inn Fields, W.C., where the Hunterian Museum is open to American graduates on presentation of visiting cards. Nearest station, Chancery Lane ("Tube"). Omnibuses to Great Turnstile, Holborn, or Law Courts, Strand.

EDINBURGH.

In Edinburgh, arrangements for post-graduate instruction are not very plentiful, and information is not at present forthcoming as to details, but application should be made to Dr. Logan Turner, 27 Walker street, Edinburgh, who will forward information when the arrangements are complete.

DUBLIN.

There is no organized post-graduate instruction in Dublin, except as regards midwifery, which is taught to graduates at the Rotunda Hospital, Britain street, whither a good many graduates from England go to study. It consists of two distinct hospitals, one into which, on an average, 1,800 cases of labor are admitted yearly, and an auxiliary hospital for uterine and ovarian disease, which treats about five hundred patients a year. Lectures and clinical instructions are regularly given. Accommodation is provided for a limited number of resident pupils, most of whom the Master (Dr. R. D. Purefoy) states are senior qualified men. Fees: Interne pupils, six months, £21; three months, £12 12s.; two months, £9 9s.; one month, £6 6s. Each month after the first, if registered separately, £4 4s.; externe pupils, six months, £10 10s.; three months, £6 6s. Applications should be addressed to the Master at the hospital.

At Dr. Steevens's Hospital, Steevens' Lane, close to King's Bridge Station in the west of Dublin, four medical and eight surgical resident pupils are accommodated. These posts are often held by graduates. There are separate clinics for eye and ear, skin, throat, teeth, and diseases of women. Fees for hospital practice, nine months, £12 12s.; six months, £8 8s.; three months, £5 5s. Residence, each three months, £10 10s., which includes fee for hospital practice. The session begins on the first Monday in October. Applications to Dr. W. S. Haughton, at the hospital.

American graduates visiting the United Kingdom and intending to study, will do well to take with them their diplomas, or some other formal certificates that they are duly qualified practitioners, as at some institutions such documents may be asked for.

POST-GRADUATE INSTRUCTION IN GERMANY AND AUSTRIA.

The American post-graduate in medicine, arriving upon German soil, will find it no easy matter to take a comprehensive survey, and to select from that wide scope of opportunities the line of work he demands, or learn how to obtain it.

BERLIN.

In a general way, Berlin has to-day most to offer the student in Germany. The university itself is the largest and, with an abundance of clinical material and excellent teaching facilities, deserves to be the Mecca which foreign medical students have made it in past years.

Aside from the university lectures, which are framed to meet the requirements of the undergraduate, but which are also to be recommended to the physician seeking more advanced study, there are numerous private courses and clinics, conducted usually by associate professors or assistants. These latter courses are run from month to month at the various polyclinics or dispensaries, the ambulatory material being used for teaching purposes.

It may be well to state here in the outset that the term "university lecture," which occurs frequently in what follows, is used in contradistinction to private courses or clinics; the distinction is made on account of the custom of visitors and foreign students to attend these lectures without paying the university fee imposed upon the undergraduate.

The private courses, on the contrary, are made up of small classes; it is presupposed that the participants are physicians and are well grounded in the rudiments and desire more advanced work in these subjects. The prices for these private courses vary, the operative courses being the more expensive.

To enter more in detail demands an analysis of the subject at hand, and a special consideration of the various departments in medicine.

Surgery.—The surgeon to the Königliche Charité, Professor König, holds a university clinic daily from 9.30 to 11 o'clock A.M. The material presented is varied, and is so selected that in the course of the year the undergraduate student obtains a general survey of the various departments of surgery.

To the average hospital graduate, or the physician in active practice, this clinic will be found somewhat elementary, with the exception, perhaps, of surgery of bones and joints, in which field the clinic is particularly rich. Hardly a day passes in which one or more such cases are not presented and operated upon.

Von Bergmann also holds a university clinic,

FIG. [illegible].—PROF. VIRCHOW'S LECTURE AT THE UNIVERSITY OF BERLIN.

the material being, perhaps, the most varied in Europe. The hospital is one of the city charity organizations, "Rettungs Gesellschaft" or Life-Saving Society (Ziegel Str. No. 5).

Von Bergmann's lectures are held every afternoon from 2 to 4 o'clock, and are, perhaps, the most scientific dissertations upon surgery that are to be heard in Germany. Even the American with a very fair understanding of the German language experiences much difficulty at first, as do also the German students, in understanding Bergmann, his articulation, owing to facial paralysis, being very indistinct.

This clinic is run in a most methodical manner. The case is presented, the history read, the clinical features are demonstrated, and then a short dissertation upon the pathology, after which the operation is performed.

In past years, during the month of April, von Bergmann gave an early morning course in operative surgery on the cadaver. Whether or not this is to be continued cannot now be determined.

Lexer, the docent to this clinic, holds a university lecture and clinic on minor surgery between the hours of 5 and 7 P.M., three times a week, in von Bergmann's amphitheatre and on alternate afternoons an operative course on the cadaver during the same hours. These university courses are all attended by Americans free of charge.

Besides these courses the first assistants of the two divisions also give operative courses upon the cadaver. These later courses are very good, and as they are largely patronized by the post-graduate student, the hours at which the courses are given are arranged at the convenience of the students. The fee is fifty marks a course.

Perhaps, the greatest technician, if not also the foremost thinker, in surgery in Berlin is Professor Israel, chief of one of the life-saving societies (August Strasse No. 12).

Israel does not hold a university professorship nor clinic. His operating room is small and accommodates only six or eight spectators. He operates Mondays, Wednesdays, and Fridays from 12 to 2 o'clock. The service is general surgery. Nowhere in Europe will the visitor find exercised stricter attention to asepsis on the part of the surgeon and entire corps of assistants, nor more determined and careful execution of the operation.

The visitor who expects to find Israel doing kidney surgery daily will be disappointed. Israel's large statistics upon surgery of the kidney is the result of the accummulation of years of observation. If, however, he be fortunate enough to be present at such a time, he will hear in a few words a discourse upon Isreal's ideas and conclusions upon this subject. The visitor is welcome each operating day and, for the asking, will be mailed postal cards with list of operations for the succeeding day.

Körte, the surgeon to the Krankenhaus am Urban, operates daily from 12 to 2 o'clock. Urban can be reached by trolley car in about one-half hour from the center of Berlin.

It is customary here as elsewhere when the visitor is given entrée to the operating room, and where students are not required to be present, to hand in one's card and be presented to the surgeon in charge.

The service here is also general. Körté's technique in abdominal surgery is considered brilliant, and the American visitor will be pleased to note the similarity between the technique adopted by him and that practised by American surgeons.

The Krankenhaus Moabit is reached by trolley car in three-quarters of an hour. Here Sonnenberg operates afternoons, beginning at 2 o'clock. There is very little here specially to entice the visitor. The service is general and appendectomies are scarce. Now and then in the wards is to be seen a case of acute appendicitis which is treated expectantly; if abscess occurs, operation is still further delayed until adhesions are firm, and later the abscess is drained, all being done in the old way that was practised ten and fifteen years ago.

Hahn, at the Friederichshain Krankenhaus, is one of the younger men, who encourages visitors and treats them cordially.

Gynecology.—The gynecologists giving university courses are Gusserow and Ohlshausen; Gusserow at the Charité and Ohlshausen at the Frauenclinic.

Both these clinics are visited by the foreigner. The general opinion of the American student is that these clinics are too elementary, and he finds, as a rule, that he can spend his time to better profit.

Ohlshausen holds an operative clinic from 8 to 10 A.M., and lectures from 10 to 11 A.M. Gusserow lectures at the Charité from 11 to 12 A.M., and operates later. A point in evidence that the above-mentioned clinics do not supply the demand of the American student is that they do not attend them as a rule, but enter a course given by two of the assistants of Gusserow. This is a practical course in diagnosis at the polyclinic, and meets three times weekly. The students examine about eight patients each day. The course is given by Blumreich and Wolf, and costs fifty marks a month. Therapy and the use of pessaries is also taught and, to a large extent, practised by the students.

Aside from these two university courses, and the private post-graduate course mentioned above, are numerous private hospitals where visitors are welcomed, such are the private institutions of Dührrsen, Makinroth, Orthmann, and others.

One of the best private post-graduate courses in gynecology is that of Orthmann. He gives two courses, the one in gynecological diagnosis, a practical course of examination of ambulatory patients, and, on alternate days, an operative course on the phantom, in which each member of the course performs all the operations. These courses cost seventy-five marks each and are to be highly recommended. These two courses are carried out by Orthmann himself, who has succeeded Martin, and gives the same couse that his predecessor established. The course is limited to six men, lasts one month, and is held at his private hospital on Elsasser street. The student has also the option of seeing all other operations performed.

Landau has a very fine institution, and gives a course similar to that of Orthmann with the exception of the operative course. The price for this course is also the same as that of Orthmann's.

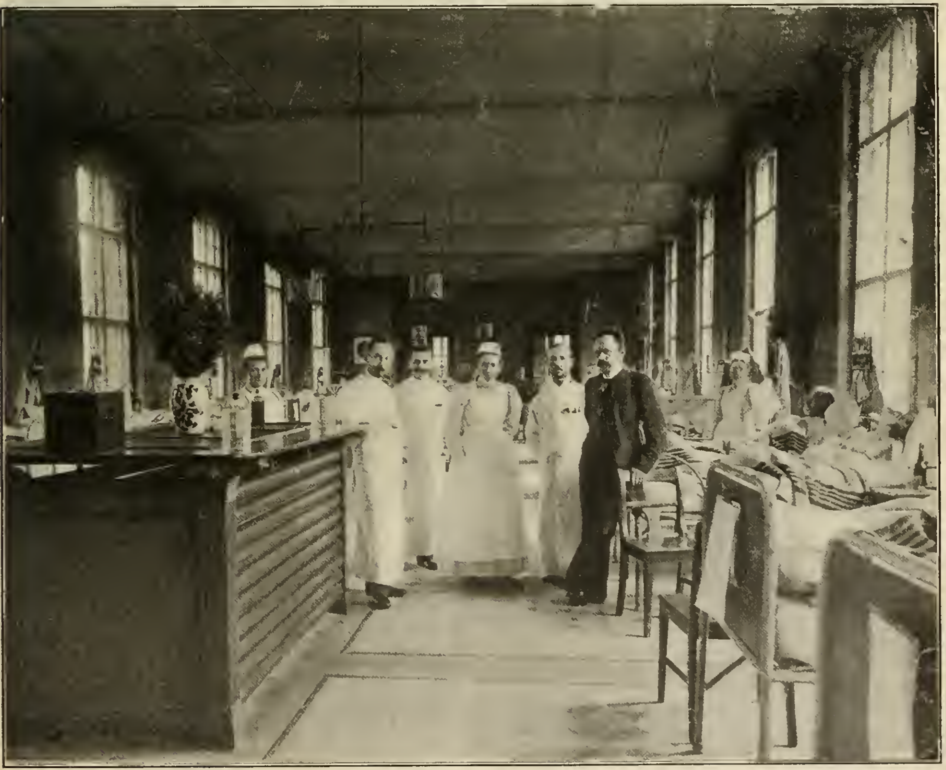

FIG. 2—TYPICAL WARD OF BERLIN CITY HOSPITAL; PROF. KOENIG

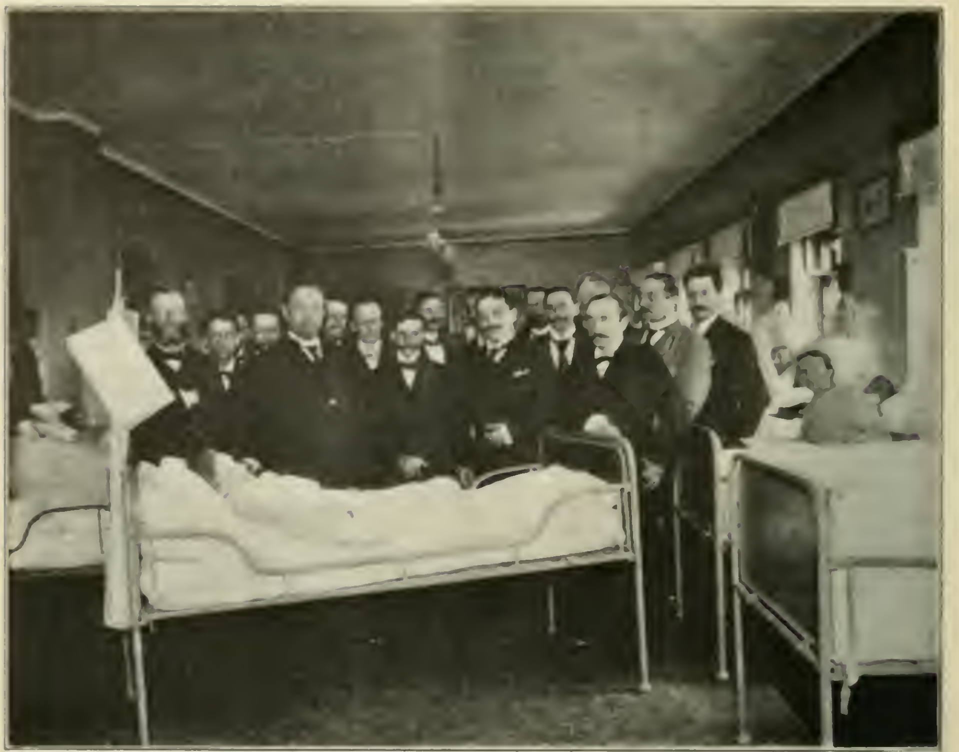

FIG. A WARD IN THE CHARITE HOSPITAL, BERLIN, PROF. V. LEYDEN

An additional advantage to the student in associating himself with this institution is the well-equipped pathological laboratory. In conjunction with the course in gynecology, Pick gives a course in pathological anatomy and also a special course in gynecological pathology. Landau is very amiable to visitors, conducts them through his wards, and invites them to witness operations.

Internal medicine in Berlin is not made as accessible to the post-graduate student as it is in Vienna; a comparison here is, perhaps, out of place. In a general way it may be true that thought in internal medicine in Berlin is somewhat in advance of that in Vienna; that is, that the pure science of medicine is worked up more thoroughly.

The American physician in search of practical work in this field will be surprised to know with what ease he can become a voluntar (voluntary assistant) in some of these clinics. Leyden, more particularly, is rather free with this courtesy, and often has several Americans working in his wards and laboratories, who remain there for an unlimited length of time free of charge, and who, later on, in their service are entrusted with greater responsibilities.

Individual research is encouraged by the professor and his assistants, and much is done to facilitate the work of the student.

It might be well to state at this point that in most instances it is quite unnecessary to present a letter of introduction in order to be received by most of these men, the visiting card very often is all that is required.

Gerhardt, Senator, and Leyden all hold university clinical lectures at different hours during the day. These lectures, like other university lectures, are paid for by the undergraduate German student, who is matriculated in the university, but are frequented daily by foreigners graduated in medicine who do not pay and are cordially received.

Senator's clinics are the most popular in internal medicine among the Americans. Gerhardt's and Leyden's are more elementary and more within the scope of the undergraduate student.

Strauss, the assistant of Senator, gives a practical course in internal medicine in Senator's wards. This is one of the very few courses in internal medicine given in Berlin, conducted in the manner of internal courses in Vienna. The course is one of daily instruction, two hours at the bedside, including theoretical lecture, each course covering a period of one month, and costs seventy-five marks.

Dermatology.—The skin clinics of Professors Lassar and Lesser are also university clinics to which the foreigner is invited. If a comparison be also allowed here it may be said that the American student in this particular line can get far more in Vienna than he can in Berlin. Both of these clinics are held in large rooms, where the student does not come in contact with the patient; sees him only at a distance or close by only for a moment, whereas, in Vienna his relation with the patient becomes more intimate. Joseph, who has a private skin clinic, gives a private course in diseases of the skin in which the system is modeled after that of the Vienna school. This course, which is by all means the best, is of one month's duration, costs 100 marks, and is to be highly recommended. Laboratory work in the pathology of the skin is included.

Heubner, the professor of skin diseases at the "Charité," holds university clinics daily from 12 to 1 P.M. This clinic is also considered too elementary by the American post-graduate student.

Pediatrics.—Baginsky gives a course at the Kaiserin Friedrich Spital, which is, probably, one of the best to be had in Europe. This course also covers the period of one month, and costs one hundred marks. The abundance of material here, and the facilities for pathological work, make this clinic unparalleled. A number of Americans who have taken courses here for one or two months, and who have cared to continue the study of this specialty, have been shown the courtesy of being allowed to continue their work and follow lines of individual investigation for an unlimited length of time. Another course on diseases of children is given by Cassel from 12 to 2 P.M. at his polyclinic. The price of this course is 50 marks a month.

FIG. 4.—PROF. GERHARDT OF THE UNIVERSITY OF BERLIN, CHIEF OF THE DEPARTMENT OF LARYNGOLOGY AT THE CHARITÉ HOSPITAL.

Diseases of the Nose and Throat.—A very excellent course is given by Fränkel (Ziegel Strasse No. 5) from 5 to 7 P.M., a large amount of material is put in the hands of the students and treatment is largely entrusted to them.

Jansen gives a university course in rhinology to the undergraduate students, consisting of lectures and practical work (Karlstrasse No. 35). The course is seldom frequented by Americans. The visitor to Berlin will find it to his interest to see some of Jansen's operations upon the accessory sinuses of the head. Not alone are these operations bold and followed by considerable deformity, but elsewhere in Germany, and particularly in Vienna, are entirely discarded, this work being one almost exclusively intranasally.

Diseases of the Stomach.—The university lecture is given by Ewald. This includes dietetics and a practical course in diagnosis at the Augusta Krankenhaus.

Boas also holds a university clinic similar to the preceding. American students are frequently permitted to enter this clinic as voluntary assistants.

A course that is planned more particularly for advanced students is given by Cohnheim at his polyclinic. The course lasts one month and costs 100 marks. Cases are clinically demonstrated and examined by the students; the chemical and microscopic examination of stomach contents and fæces are also made. This course is by far the most popular among post-graduate students. The course given by Kutner is, in the main, the same as that of Cohnheim.

Neurology.—A university course upon diseases of the nervous system is given twice a week by Oppenheim. This clinic consists of demonstration of cases, together with a theoretic lecture. In conjunction with this is given a laboratory course upon the anatomy and pathology of the nervous system. Students desiring to specialize in diseases of the nervous system are given every opportunity for study, also laboratory facilities free of charge.

Another university course on diseases of the nervous system is given every afternoon between 5 and 6 by Professor Mendel (Dorotheen Strasse No. 8). Although this is a university course, it is rarely frequented by undergraduate students, but well attended by foreign visitors. It is customary for the American student to add this course to his daily curriculum. This course is also enjoyed free of charge, and is one of the best clinics on diseases of the nervous system to be heard in Europe.

The university course on mental diseases is held at the Charité by Professor Jolly, between the hours of 11 and 12 o'clock. The material is very abundant and facilities are given the foreigner to work in this department as voluntär. A private course in electrodiagnosis and nervous diseases is

PROFESSOR NEUMANN AND CLASS, SHOWING THE ARRANGEMENT OF STAIRWAY [illegible] TO THE [illegible] AT THE UNIVERSITY OF VIENNA.

given by Toby Cohn. The course costs 50 marks and is to be recommended.

Cystoscopy.—In recent years the Americans in Berlin have created a demand for theoretical and practical work in cystoscopy. The German hospital assistant will often go far out of his way to make rash promises in order to earn an American dollar, and as a result there are a number of such courses given by men who have neither the material nor the requisite learning.

Both Nitze and Caspar, give courses upon the theory of cystoscopy, but what the American demands in this field is practical work. It might be well then to enumerate here only two courses, both of which include a fair amount of practical work, at least enough to enable the student to continue practical exercises upon material which will later come to him.

The one course most to be recommended is that given by Jacoby, first assistant to Nitze. This course is given upon the male with phantom exercises and a thorough survey of the theory. The course costs 100 marks and is given at Jacoby's residence, König Str. No. 47.

The other course upon the female by Knorr (Grosse Frankfurter Str. No. 51) is also very good, but one is not taught the difficulties encountered in the male bladder. In the female bladder the Germans have not adopted direct cystoscopy as advanced by Kelly, but use a modified Nitze instrument.

Orthopedics.—Heretofore a very excellent course has been given in orthopedic surgery by Wolff and Joachimsthal (Karl Str.). Owing to the recent death of Wolff, post-graduate course work in this field will, probably, be rearranged. A limited number of Americans are permitted to work in this clinic without charge.

Professor Zabladowsky gives a course on massage, for which he charges 50 marks a month; the student is taught the various technicalities of this art and is allowed to practice upon patients.

VIENNA.

Surgery.—A large number of Americans go to Vienna, hoping to find there good courses of study in surgery. Many of them are disappointed. The student who comes directly from the medical college, or who has had an inferior surgical training in a small hospital, or whose practical work in surgery has only been that which he has been enabled to do during the first years of his practice, will find the university lectures and clinics of Gussenbauer and Eiselsberg much to his liking. Both of these clinics are held at the Allgemeiner Krankenhaus every morning. These clinics are framed for the undergraduate student. There is scarcely a clinic anywhere in the world which deals so thoroughly and covers the ground so well as these. Foederl and Friedlander, the assistants respectively of Gussenbauer and Eiselsberg, give also courses in surgical diagnosis. The price for these courses varies according to the number of men in the course, the assistants demanding that their time be paid 20 gulden an hour. The time at which these courses are given is arranged to suit the convenience of the students. These two courses supply the demand of students who previously had not the advantage of seeing surgical conditions from a clinical and diagnostic standpoint They are invited to the operation, and cases during convalescence are again presented.

Both Föderl and Friedländer also give operative courses on the cadaver. The student performs the operation and learns practically the technique the choice of operation lies with the students.

These courses are not all arranged for the advanced student. The man who wishes to do more advanced or special surgery must make special arrangement with the assistant, telling him exactly what he wants, together with arrangement of price, inquiring also of an assistant who is best versed in that particular branch. Almost any operative work on the cadaver can be had. A student wishing to do operations on the cadaver upon the accessory sinuses of the head may associate himself with one or two other men desiring the same work, and arrange with one of the assistants of Chiari or Kochier in rhinology, and within a very few hours obtain that work. Or if he care to work up surgery of the rectum, he need only to present himself to Hochenegg, who gives such a course.

Aside from these courses there is much in surgery to be seen. Both Hochenegg and Gersuny receive Americans very cordially at their polyclinics. Frank has his own wards in the Krankenhaus, but gives no courses.

Internal Medicine.—The clinical lectures of Nothnagel and Neusser are both given at the Allgemeines Krankenhaus every morning. Both are university lectures. Again the distinction must be made that Nothnagel's clinic is well attended by undergraduate students, whereas Neusser's clinic is incomprehensible to the undergraduate, and the lecture room is entirely occupied by physicians.

Neusser's lectures are, probably, the finest series of clinical dissertations to be heard in Europe.

Special diagnostic courses in internal medicine are given by the assistants of the above clinics. Kovacs, a former assistant of the Clinic Neusser, now Primarius and in charge of his own wards, gives the best clinic in Vienna. This course is limited to ten men and costs 30 gulden ($12) a month. It is very difficult to enter this course, inasmush as the places are so in demand that one student holding a place reserves it or gives it up with the provision that upon a certain date the place falls to the candidate he names.

Other courses, certainly very excellent, are also given by Türk and Stejskl in Neusser's wards. These courses are also practical at the bedside and cost 30 gulden a month.

Türk also gives an excellent course upon the blood. The course is practical and limited as regards number of participants by the students themselves. Türk advises that not more than four men enter at one time. The course costs 8 gulden for one hour of the instructor's time, the course usually being completed in from eight to twelve hours.

Hammerschlag, an assistant of Nothnagel, gives, by request, a course, of about four to six weeks' duration, upon diseases of the stomach. This course is also practical, including bedside and laboratory work.

Pathological Anatomy.—Courses in this subject in Vienna are so arranged as to enable the student to cover as much ground in a comparatively short

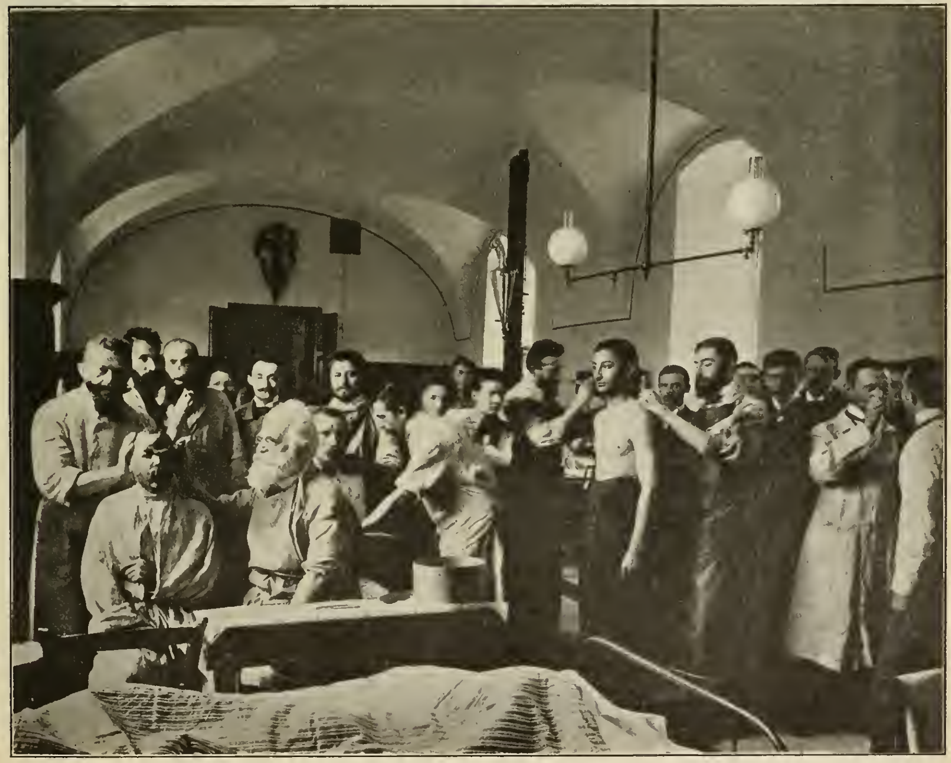

FIG 6.—CLINIC IN SYPHILIS AT THE UNIVERSITY OF VIENNA; PROF. LANG

[illegible] MEDICAL WARD IN THE [illegible] HOSPITAL AT EPPENDORF-HAMBURG, PROF. RUMPF.

space of time as possible. The university lecture of Weichselbaum is usually not attended by the advanced student.

A very popular course—the only one in gross pathology—consists of demonstrations of the various cases that came to autopsy the previous morning. This course is given daily, from 5 to 6 P.M., by Professor Albrecht and costs 30 gulden per month. It is limited to twenty students. The course is an exceptionally good one, and is to be recommended to all students. A one-month course in bacteriology is given by Ghon, in which the entire field is surveyed, both theoretically and practically. This course is given from 11 to 1 o'clock, and costs 30 gulden. The student is permitted to spend the entire day, or as much time as he chooses, in this laboratory, and may follow original research.

Courses in histological pathology are given by two other assistants, Stoerk and Landsteiner. In these courses are taught methods of preparation, of sectioning, and of staining. Special fields of histological pathology are also taught, such as gynecological pathology, pathology of diseases of nose and throat, etc. The abundance of pathological material, which has accumulated for years, is placed at the disposal of the students. These courses also cost 30 gulden a month, all laboratory privileges also being extended the student.

Neurology.—The university lecture upon the subject of nervous diseases is held three times weekly by Krafft-Ebing. The student, as a usual thing, does not rely upon these lectures for his work in psychiatry or nervous diseases.

Chvostek also holds a university lectureship upon nervous diseases, this course being largely frequented by Americans and other foreigners. The course is adapted to the scope of the undergraduate.

The course, which in the past year has best of all supplied the demands of the American student in nervous diseases, is given by v. Frankl-Hochwart. This course, however, excludes psychiatry, and is given only upon request. The fee is 30 gulden a month.

A course in neuropathology, consisting chiefly of laboratory work, is given by Obersteiner. The student is required to spend a large portion of the day in the laboratory, and is assisted in any line of research work which he may care to undertake.

Heretofore, the foreign student has been unable to find good work in the department of children's diseases in Vienna. Now that Escherich has been appointed to the chair at Vienna, he will, probably, extend the same courtesies to American students as was his wont in Graz.

During the past year Primarius Knöpfelmacher, at the Carolinen Kinderspital, has also given a course upon the request of American students. The material at the clinic is very abundant, and the cases for demonstration are carefully selected and well presented. The infectious wards are also open to the students for study. This course is limited in number to twelve men and costs 25 gulden a month. At this hospital also the physician is given much latitude and may become a voluntary assistant, spending the greater part of the day at the institution free of charge.

Dermatology.—The opportunity for the study of diseases of the skin can be equalled nowhere else in Europe. The university lecture upon diseases of the skin since the death of Kaposi has been delivered by the assistant, Kreibich. The student seeking more advanced study in this field does not content himself with this lecture, but enters one or both of the private clinical courses given by Kreibich and Weidenfelds. Patients are brought for the direct inspection of the students; sufficient time is given them for careful study of the various lesions and a short review of the pathology. The charge for this course is 25 gulden a month. The time chosen is usually in the morning, but subject to the convenience of the participants of the course.

Members of these courses are invited to the ambulatorium at 10 o'clock in the morning, where an enormous quantity of material can be seen daily. A microscopical course is given upon the pathology of the skin, including laboratory work.

Nose and Throat.—Several very excellent courses are given in diseases of the nose and throat. One at the Krankenhaus, where there is a great abundance of material to be seen. This course is given by Chiari and his assistants, and is to be selected by the student who is familiar with the technique of rhinological and laryngological examination, but who wishes to see various pathological conditions.

Another course, conducted in a similar manner, is given by Kochier at the polyclinic on Marienstrasse. Here the student is given more detailed instruction in the technique of examination. The material at this dispensary is, perhaps, not so rich, but the student is given wider opportunities, treatment is largely left to him, and if he choose to continue this course for several months, many of the minor operations, such as the removal of turbinated bodies, adenoids, tonsils, polypi, etc., are entrusted to him. Both of these courses are given from 11 to 1 o'clock, and cost 25 gulden a month.

Undoubtedly, the best course is given by Hajck. This course is recommended to the student who wishes to perfect himself in this branch to the exclusion of others. The course covers a period of three months of lecture upon the anatomy and pathology of the nose and throat, together with clinical demonstrations. The more fortunate students are allowed to work in Hajek's private office at his clinic from 11 to 1 o'clock and are given opportunity to do pathologycal laboratory work. This course costs 100 gulden.

Otology.—The post-graduate student in diseases of the ear will find ample opportunity for study in Vienna. Professor Politzer encourages work in many ways in this specialty, and the student is given a table in the ambulatorium, where he sees daily a large number of patients. Advanced courses are given in diseases of the ear, together with operative exercises upon the cadaver, by two of the assistants, Frey and Alexander. The anatomy and pathology of the temporal bone is minutely studied. The various operations for mastoid disease are performed by each student, including the various approaches to the brain and lateral sinus for disease complicating mastoiditis. The student, after spending two or three months at this clinic, is allowed to

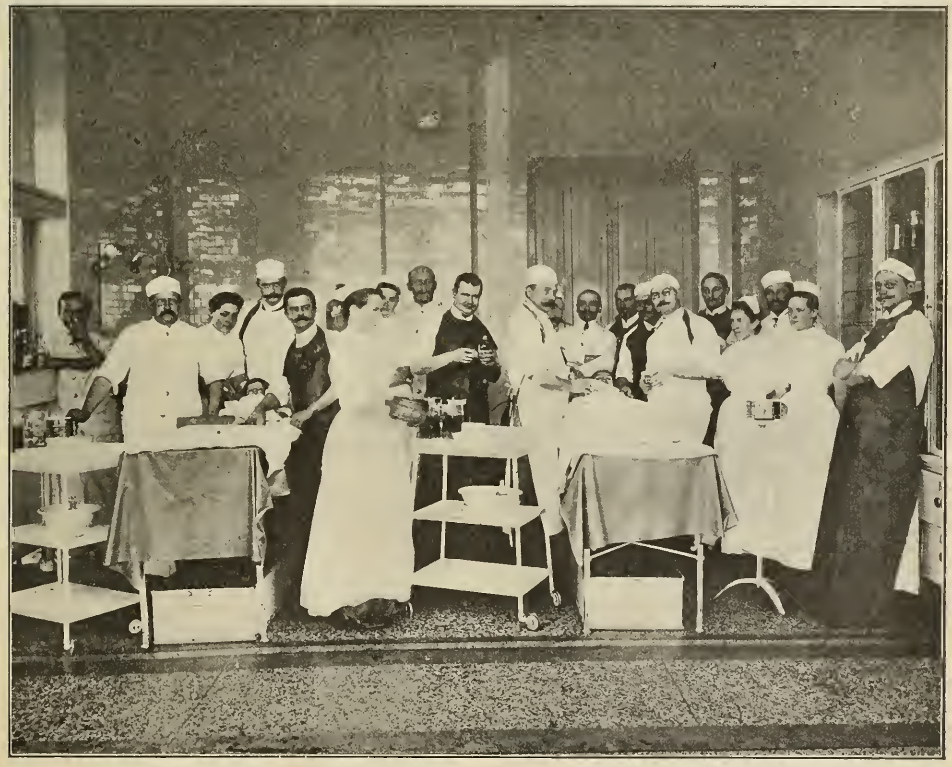

FIG. 8.—THE LARGE OPERATING ROOM IN THE GENERAL HOSPITAL AT EPPENDORF-HAMBURG. SECOND HALF, WOMEN'S SIDE. THE ROOM CONTAINS SIX OPERATING TABLES ALL OF WHICH ARE OFTEN IN USE AT ONCE

[illegible]

to manual operations upon the patients at the clinic.

Urbantschitsch holds his clinic at the polyclinic where may be studied that branch of this specialty to which Urbantschitsch has devoted so many years of his life, namely, to the improvement of hearing in the deaf.

Ophthalmology. In the advanced study of the diseases of the eye the student is also given many facilities. Here also the Professor encourages and invites foreigners to his clinic for study. At the clinic the student examines all patients at the ambulatorium and is invited to the university lectures of Professor Fuchs. The first assistant, Sachs, gives a course upon refraction and ophthalmoscopy.

For the beginner in ophthalmology who has had no experience in diseases of the eye or the use of the ophthalmoscope and who wishes to advance himself there are two courses—the one given by Sachs, the other by Elschnig. The one given by Elschnig is more to be recommended. In this course personal instruction is given beginning with the rudiments, whereas the course of Sachs is for the more advanced in the use of the ophthalmoscope, special attention being given to fundus diagnosis.

Genitourinary Diseases. Advanced work in genitourinary diseases is to be had at the clinics of Finger and Ehrmann. Finger's course is a university course and covers the field of gonorrhea and syphilis most thoroughly from a theoretical standpoint. Cases are also demonstrated, but more material may be seen at other clinics. Finger's course costs 15 gulden and lasts about one and one-half months.

The course given by Fritsch carries the student well through the subject of gonorrhea, together with its complications and treatment. Much material is shown and the students are allowed to do much in the way of treatment. This course covers a period of three months, includes cystoscopy, and costs 100 gulden.

By far the greatest amount of syphilis is to be seen at the morning clinic of Professor Neumann. This is a university course, held also at the Krankenhaus. The course cannot be said to be a good one as far theory, but much material is seen.

The student who wishes to study syphilis is advised to take the course given by Matzenauer, the assistant of Neumann, at which course the same material is shown and instruction given. The course costs 25 gulden ($10) a month and is given from 11 to 12 o'clock. The student is invited also to attend the ambulatorium which is held from 10 to 11 o'clock. There is probably no clinic in Europe where so much syphilis can be seen.

Orthopedics.—The study of orthopedic surgery can be had, perhaps best in Berlin, as mentioned above. In Vienna an eight weeks' course is given by Lorenz to undergraduate students. The course is conducted much in the same manner as our courses in New York, consisting chiefly of demonstrations. The extreme conservatism which prevailed in German orthopedic surgery some ten or fifteen years ago has been to a degree relaxed and to a greater extent American methods have been adopted. Heretofore no good post-graduate course in this subject has been given in Vienna. It is reasonable to suppose, however, that if Professor Lorenz were properly approached upon this subject he would be glad to supply this deficiency.

Anatomy.—A course in topographical anatomy is given by Fandler, the assistant to Zuckerkandl, at the Anatomical Institute. The course is a good adjunct to surgical studies, inasmuch as it not only reviews anatomy, but also bings out in a new light the relation of surgery to the anatomy of the various organs.

This course costs 15 gulden ($6) and covers a period of two and a half months.

Hydrotherapy.—The numerous hydrotherapeutic institutions in Vienna are all open to inspection and much can be learned from a tour through them. Winternitz gives a short course of clinical lectures upon hydrotherapy twice a week at the polyclinic, and opportunity is given the student to work in the institution if he desires to study this field more especially.

THE SMALLER GERMAN CITIES.

In this review of post-graduate opportunities for study it has been deemed advisable to enter upon a more detailed report regarding facilities for study in the two cities, Berlin and Vienna. It is not, however, to be inferred that a visit, or even a prolonged stay, is not to be recommended at one of the smaller university towns. Inasmuch as all fields of study are to be had in Berlin and Vienna, and owing to the large attendance by Americans in these cities, courses of study are more conveniently arranged to meet the demands of the American student. It has, therefore, also been considered convenient in this report to deal with the smaller university towns in such manner as to specify in them only the several branches and the instructors in such departments who bring the town into prominence in the world of medicine.

Breslau has little to offer in the way of private courses in surgery. The university lecture given by Mikulicz may be attended daily. This lecture is intended for the undergraduate, but unquestionably the advanced student will benefit much by daily attendance. The clinic is held from 10 to 12 A.M.

The university lecture in gynecology and obstetrics is given by Professor Küstner. Visitors are invited to this clinic and are shown many courtesies by the assistants. Private courses are also given by the assistants in gynecological diagnosis, and also operative courses in obstetrics and gynecology.

Neisser lectures upon the diseases of the skin and gives a laboratory course on the pathology of the skin. Both of these courses are university courses. American post-graduate students have, upon occasions, been allowed to work as Voluntäre in this clinic, and abundant opportunity is given the assistants for pathological research.

The university at **Erlangen** is frequently visited in order to hear the lectures and clinics of Strümpell. The visitor is usually invited into the wards, and is shown through by one of the assistants. As a rule, the American finds nothing there to detain him.

Göttingen has not very much to attract the physician, except the surgical clinic of Professor Braun, held every morning at 10 o'clock, together with the pathological laboratory of Orth.

Greifswald, although one of the smaller university towns, has much to offer the advanced student in medicine.

In pathological anatomy the university lecture is given by Grawitz, together with laboratory work for advanced students. Grawitz encourages voluntary work in his laboratories. The student is given all laboratory facilities and pathological material free of charge.

Bier, the professor in surgery, besides his university lecture, gives an advanced course in theoretical and operative surgery. This course calls for a nominal fee for matriculation in the university. Another course in bone and joint and military surgery is given by the associate professor, Tilmann.

The university course in obstetrics and gynecology is given by Martin. This course includes phantom exercises.

The university at **Halle** is visited chiefly by the student in otology. Schwartze's clinic is richly supplied with material, and here also the student is given abundant opportunities for work. Schwartze also gives a special course in diseases of the ear for advanced workers. The course includes operations upon the cadaver and later upon patients. The course costs 100 marks ($25).

The university at **Heidelberg** no longer occupies the prominence in the field of medicine that it claimed some years ago. The university lecture in surgery is given by Czerny. Clinical work is given the undergraduate students in the wards and in the ambulatorium. The advanced student in surgery will find only Czerny's clinics of interest.

In internal medicine and nervous diseases, the advanced student will again find he has not the latitude given him for work that he has at other universities. His work will be almost limited to attendance at Erb's clinics.

Kraepelin holds the university clinic in psychiatry, gives an advanced course and encourages research work.

The university at **Kiel,** owing to the fact that von Esmarch has resigned his lectureship, has lost one of its attractions. The university lecture and clinic in surgery is now given by Helferich. The university lecture in internal medicine is given by Quincke.

The importance to which the university at **Leipsic** has risen is in a large measure due to Wendelenburg, Tillmanns, Curschmann, Zweifel, and Marchand. Trendelenburg gives the university lecture in Surgery; Curschmann in Internal Medicine; Zweifel in Gynecology and Obstetrics, and Marchand in Pathology. Marchand encourages advanced pathological studies, and holds this opportunity open for the American student.

Munich was visited usually with the intention of attending the clinics of Ziemssen and of Winkel. The post-graduate student usually finds nothing there to detain him long. Ziemssen gave a bedside course in internal diagnosis for advanced students, but whether this course will be continued by his successor the present writer does not know. Winkel holds the university lecture in gynecology, but there is not the opportunity for work found in other cities.

Strassburg also is not frequented by the majority of American students. The advantages which this university offers are pathological work under the direction of Recklinghausen and internal medicine under Naunyn. Recklinghausen gives an advanced course in histological pathology, together with laboratory opportunities. Naunyn gives only the university lecture in internal medicine and offers no attraction to the American student.

American students will find abundant opportunity for study in **Prag.** Chiari takes an active interest in students who go there for work in pathology. To them he throws open his laboratories, gives them a working table, allows them to make autopsies, etc. Assistance is also given in any [illegible] fees in charge.

[illegible] Wagner, where also the American student is [illegible] welcome. The first assistant in this department gives a special operative course upon [illegible] the stomach and intestines, [illegible] and [illegible]. [illegible]

The advanced courses given by [illegible] and his assistants in internal medicine are not particularly to be recommended, but post-graduate students are readily taken in the clinic as voluntary assistants.

Living Expenses.—The student intending to remain a considerable length of time in a University town, will find it to his advantage to take quarters in a pension or boarding-house, not only is the mode of living less expensive, but there he will be in contact with others whose advice may be of service to him.

It is customary among American students traveling on the continent to advise each other where to locate in other cities, this mutual interchange of advice often saving hours of search for lodgings.

In a general way it may be said that if the visitor be entirely unacquainted in a town he had better go at once to a hotel, engage a room for twenty-four hours and devote this first day, if so long be necessary, to finding lodgings.

Numerous pensions and boarding-houses will be found in the immediate vicinity of the University. The prices vary, of course, according to location and accommodations. In Berlin fair-sized rooms with service and within a very short distance of the University may be had for from 30 to 50 marks ($7.50 to $12.50) a month. The visitor will usually find it more agreeable to engage a room only—that is without meals—and visit the various restaurants which form one of the attractions of Berlin.

Rooms with breakfast cost 10 to 12 marks ($2.50 to $3.00) extra. To engage board and lodging is less advisable, because the work of the students often carries him to distant parts of town. Board and lodging may be had for from 50 to 200 marks ($12.50 to $50) a month.

In regard to location, what has been said of Berlin applies also to Vienna—that is, that good and cheap lodgings are to be had more especially in the immediate neighborhood of the Krankenhaus. The prices in general are higher in Vienna than in Berlin, and, as a rule, the accommodations are poorer.

Rooms without meals may be had from 20 gulden ($8) upward per month, and breakfast 5 to 7 gulden ($2 to $2.50) extra. Board and lodging from 50 gulden ($20) upward. The restaurants, also, are more expensive than in Berlin.

In general, the student engaging himself in a fair number of courses must prepare to spend not less than $100 per month; he may live well on $150, and extravagantly upon $200 per month.

POST-GRADUATE INSTRUCTION IN THE UNITED STATES.

THE schools devoted solely to post-graduate teaching in the United States, with the exception of a polyclinic in Philadelphia and one in New Orleans, are situated in New York and Chicago, each of which centers of population contains four.

NEW YORK.

New York city, scarcely surpassed by London in its abundance of clinical material, is exceedingly well supplied with post-graduate institutions, and with also deserving for post-graduate instruction. Its colleges and post-graduate medical schools have gained a world-wide reputation, and are superior to [illegible] to be found in Europe.

Good board and lodging may be obtained in New York at houses near the schools for from $6 to $12 a week. Simple board may be had at from $4 to $6 per week, meals being taken at restaurants.

The Post-Graduate Medical School and Hospital of New York.—This is the largest and one of the most important institutions of the kind in the United States. It is a part of the University of the State, and is under the general supervision and control of the Regents of the University, besides having been granted a special charter by the Legislature of the State. The number of physicians attending the school during the year past was [illegible].

The teaching of the school is entirely clinical or demonstrative. Hospital accommodations are exceptionally ample and practitioners may witness several important operations each day, in addition to attendance upon clinics.

There is a good laboratory, and advanced instruction is given in pathology, histology and bacteriology. The anatomical rooms are extensive, and the arrangements generally are of a high class. The babies' wards contain fifty-four beds, and the orthopedic wards accommodate thirty patients. The entire hospital contains 184 beds, the average number occupied at one time being 162. The dispensary is one of the largest in the city, and there is also attached to the post-graduate hospital a training school for nurses.

The school is exclusively for members of the profession whose credentials are satisfactory to the directors, and who have a legal right to practise medicine in the United States, or in the countries from which they come.

The school year is divided into two distinct but continuous terms. The autumn and winter courses begin on October 1 and end on June 1. The school and hospital are open during the entire year. In the summer instruction is given by the adjunct professors and instructors.

The fee for the winter session for a general ticket for a term of twelve weeks, with the exception of some courses not included in the general ticket, and for which special rates are charged, is $150, for a term of six weeks $100 is charged. The fee for the general ticket of the summer session is $35 a month, $45 for six weeks, or $125 for the whole term.

The plan of instruction is as follows: Pathology, physical diagnosis, medical chemistry, general medicine and therapeutics, climatology and pharmacology. Professor Porter is the principal lecturer upon pathology and general medicine, Professor Burt upon physical diagnosis and medicine, Professor Wilcox upon medicine and therapeutics, Professor Weber upon medicine. Professor Stubbert upon pulmonary tuberculosis, while Professor Einhorn will give special courses in diseases of the stomach twice during the season.

Pathological histology and bacteriology are taught by Professor T. Brooks and Benjamin F. Cline; diseases of the mind and nervous system are under the charge of Professors Graeme M. Hammond and Joseph Collins, who each give two clinical lectures weekly, and Professor Morton deals with electrotherapeutics.

In surgery the professors are Seneca D. Powell, W. B. De Garmo, Daniel Lewis, Willy Meyer, Samuel Lloyd and Robert T. Morris. Adjunct professors: Theodore Dunham, Carter S. Cole, Franz Torek, Forbes Hawkes, and Neil Macphatter, together with a large staff of instructors. The clinics and dispensary instruction in this department occupy from three to six hours daily.

Orthopedic surgery is taught by Professors A. M. Phelps, W. O. Plimpton, and instructors Drs. D. W. Marston and D. D. Ashley.

The course in diseases of the rectum and anus is given by Professor Samuel G. Garit and instructor Dr. Kenneth Keith MacAlpine.

The department of surgical anatomy and operative surgery on the cadaver is presided over by Professor John J. McGrath, with the assistance of Adjunct Professors William S. Bainbridge, Clarence A. McWilliams, and a corps of instructors. The professors of the diseases of women are Drs. Bache McE. Emmet, Jonas R. Nilsen, Hermann St. J. Boldt, George M. Edebohls, A. Palmer Dudley, Ralph Waldo, Adjunct Professors Abram Brothers, George G. Ward, Jr., Charles F. Adams, J. N. West, and several instructors.

Teaching in the department of pediatrics is by Professors Henry Dwight Chapin and Augustus Caillé; Adjunct Professors John Dorning, Andrew von Grimm, Charles O. Maisch, and instructors. Professors L. Brodhead and John O. Polak give two lectures each week on obstetrics, while practical courses in the subject are given by Professor Brodhead and Instructor Dr. Moore.

Clinics in diseases of the eye are held in the school by Professors Moore, Valk, Peck, Davis, Irwin, and Parker. Professor Roosa operates or gives a clinical lecture twice a month during the winter session. At the Manhattan Eye and Ear Hospital, instruction in diseases of the eye is given by Professors Emerson, Lewis, and Van Fleet, and by Drs. Deynard, Weisner, Carhart, and Thomson. A course in refraction and ophthalmoscopy is given at the same institution by Dr. Kinney on Tuesday and Thursday afternoons, and Drs. Kinney and Thompson give a laboratory course on the histology and pathology of the eye. Professors of diseases of the ear are D. B. St. John Roosa, W. O. Moore, J. B. Emerson, Wendell C. Phillips, and James F. McKernon.

Two lectures each week are given by Professors Phillips and McKernon at the school. Daily clinics for diseases of the ear are given by Drs. Crawford and Rae. Professor Phillips gives instruction in diseases of the ear at Manhattan Eye and Ear Hospital.

The professors of diseases of the nose and throat are Clarence C. Rice, H. Beaman Douglass, and Thomas J. Harris. Daily clinics are held at the school, and classes in which practical work may be done by the students are conducted two evenings each week at the school by Dr. James B. Ferguson.

Drs. Eugene Fuller, and Ramón Guitéras are the professors of venereal and genitourinary diseases, and together with the adjunct professors and instructors, give courses in this branch of surgery. Six hours each week are devoted to it.

Drs. W. Bedford Brown and Charles Warrenne Allen are the professors of diseases of the skin, and Dr. Thurston G. Lusk adjunct professor. Clinical lectures on dermatology are given twice a week by Drs. Brown and Allen. Instruction during dispensary hours is also given by Drs. Lusk and Mayer.

The New York Polyclinic Medical School and Hospital.—This school was organized during 1880-81, and opened in 1882, and was the first post-graduate medical school in America independent of an undergraduate institution.

The polyclinic hospital contains eighty beds, and the wards and private rooms directly adjoin the surgical and medical amphitheatres. A dispensary is supported in the main building, and from 150 to 200 patients are treated daily.

Practitioners who are graduates of medical colleges, or have a legal right to practise medicine, will be admitted to the course of instruction at the discretion of the faculty. A general ticket admitting the holder to all the clinics for six weeks (laboratory and operative courses excepted) costs $100; for three months, $150; for six months, $250; and for one year, $350. Tickets for single courses can be taken, the cost ranging from $50 for six weeks, $90 for three months, $160 for six months, and $280 for one year, to $15 for six weeks, $25 for three months, $40 for six months, and $60 for one year. There are, besides, single courses, as follows: Surgical operations on the cadaver, each course, $25; clinical microscopy and urinary analysis, each course, $20; practical histology and pathology, each course, $20; bacteriology, each course, $20; intubation, each course, $15.

Certificates of attendance on one or more of the branches of study will be given matriculants on completion of the course at the discretion of the faculty. No certificate will be given during the summer session for a course of study of less than four weeks' duration.

The plan of instruction is as follows: Gynecology —Professor W. Gill Wylie holds a clinic on Tuesdays at 9 A. M., and operates at Bellevue Hospital Wednesdays at 3 P.M. Professor J. Riddle Goffe holds clinics on Wednesdays and Saturdays at 9 A.M., and operates at the City Hospital Mondays and Thursdays at 2 P.M., from February 1 to June 1, and at the Skin and Cancer Hospital from August 1 to February 1. Professor Pryor holds clinics on Mondays at 9 A.M., and Fridays at 3 P.M. Adjunct Professor Ladinski holds a clinic on Wednesdays at 3 P.M. Adjunct Professor R. H. Wylie holds a clinic on Fridays at 9 A.M. Dr. Porter holds a clinic on Saturdays at 5 P.M. Dr. Burtenshaw lectures on operative gynecology on Wednesdays at 1 P.M.

The clinics on general surgery are held from 11 to 12 M. on Mondays and Thursdays, by Professor John A. Wyeth; on Tuesdays by Professor Robert H. M. Dawbarn, and on Wednesdays and Saturdays by Adjunct Professor J. A. Bodine. There is a large staff of lecturers, instructors, and clinical assistants attached to this branch. The course in operative surgery and surgical anatomy, of which the professor is Dr. Robert H. M. Dawbarn, consists of twelve lessons of two hours each, covering a period of three weeks, and given during the evenings. Work begins on or about September 15 and ends in June.

The professor of orthopedic surgery is Dr. W. R. Townsend; adjunct professor, Dr. Royal Whitman, and instructors, Drs. W. B. Thompson and J. H. Waterman. Beginning September 15, Professor Townsend gives four series of clinical lectures on Fridays from 11 to 12 M. Adjunct Professor Whitman holds a clinic on Wednesdays from 5 to 6 P.M.

Professor Charles H. Chetwood holds clinics in genitourinary surgery on Tuesdays and Fridays from 4 to 5 P.M. An ample staff is attached to this branch.

The course of rectal surgery consists of two clinics a week, from 1 to 2 P.M. on Thursdays, and 3 to 4 P.M. on Mondays. The professor is Dr. James P. Tuttle, assisted by a staff.

The professors of clinical medicine are Drs. I. Adler, W. H. Katzenbach, and Morris Manges, with a large staff. The clinics in this department are held by Professor Katzenbach on Wednesdays and Saturdays; by Professor Adler on Tuesdays and Fridays, and by Professor Manges on Mondays and Thursdays, from 2 to 3 P.M. Professor W. W. Van Valzah and Adjunct Professor J. D. Nisbet give a course on the diseases of the stomach and digestive system on Mondays and Thursdays from 4 to 5 P.M.

Four clinical lectures a week are delivered on diseases of the skin by Professor Edward B. Bronson from 1 to 2 P.M. on Mondays and Fridays and by Professor Andrew R. Robinson at the same hour on Tuesdays and Saturdays.

Four clinics a week from 1 to 2 P.M. are held in the department of diseases of the eye on Tuesdays and Saturdays by Dr. R. O. Born, and on Wednesdays and Fridays by Dr. Cary. The professors besides Dr. Born are Drs. W. B. Marple and David Webster (Emeritus).

Dr. August Seibert is professor of diseases of children, assisted by a large staff. Clinics are held Mondays and Fridays by Dr. Seibert, Tuesdays and Saturdays by Dr. Kerley, Thursdays by Dr. Baron, and on Wednesdays instruction in intubation is given by Dr. Weber.

In the department of diseases of the throat and nose daily demonstrations are given of the latest methods of inspection, diagnosis, and treatment of the diseases of the nose, mouth, pharynx, and larynx by the four professors of the subject; from 4 to 5 P.M. on Tuesdays and Fridays by Professor Delavan, on Wednesdays and Saturdays by Professor Gleitsmann, on Mondays and Thursdays by Professor Quinlan, and from 8 to 9 P.M. on Tuesdays and Fridays by Professor Myles. Professor Quinlan also holds a clinic at the City Hospital on Wednesdays at 2 P.M.

The instruction in diseases of the ear embraces clinical lectures on Mondays and Thursdays from 2 to 3 P.M. by Dr. Frederick Whiting, the other professor in this department is Dr. Oren D. Pomeroy (Emeritus).

In the department of diseases of the mind and nervous system clinics are held by Dr. Sachs on Tuesdays and Thursdays, from 3 to 4 P.M., and by Dr. W. B. Pritchard on Fridays from 3 to 4 P.M. A course on the normal and pathological anatomy of the nervous system is given by Dr. Wiener on Wednesdays from 3 to 4 P.M.

The professor of obstetrics, Dr. Edward A. Ayers, holds clinics in this department from 5 to 6 P.M. on Tuesdays, and on Friday clinics are held by Dr. Julian Rosenberg.

Histology, pathology, bacteriology, clinical microscopy and clinical chemistry are studied under the direction of Dr. F. M. Jeffries, lecturer and director of the laboratory.

The School of Ophthalmology, Otology, and Laryngology of the New York Eye and Ear Infirmary.—This institution is the oldest and largest in the city devoted to the special treatment of diseases of the eye, ear, nose, and throat. The building is almost new, and has all modern conveniences.

Clinical instruction is given in ophthalmology, otology, and laryngology by a large and capable staff of teachers. Instruction is given throughout the year, and in addition to the clinical instruction, certain special courses are given, twelve lessons in refraction, twelve lessons in ophthalmoscopy, and twelve lessons to six members in operative surgery of the eye. There is also given a course of twenty-one lessons in normal and pathological histology.

The fees are as follows: Tickets admitting to all clinical courses for three months, $50; to all clinical courses for two months, $40; to all clinical courses for one month, $30; to two branches for three months, $40; to two branches for two months, $30; to two branches for one month, $25; to one branch for three months, $40; to one branch for two months, $25; to one branch for one month, $20. Special courses in refraction, twelve lessons, $25; in ophthalmoscopy, twelve lessons, $15; in operative surgery of the eye, twelve lessons, $50; in normal and pathological histology, twenty-one lessons, $25; in operative surgery of the ear, six lessons, $25.

The New York School of Clinical Medicine. This school established in 1895 is conducted exclusively for qualified graduates in good standing. Classes are all limited, giving each student ample opportunity to work as if in his own office, making diagnoses, prescribing, and acquiring proficiency in the use of the various instruments in each department.

The list of teachers is a large one, and the scheme of instruction is eminently practical and aims at imparting information calculated to be of most service to the practitioner. Students are invited to operations by the teaching staff in the hospitals of the city or at the homes of patients. The plan of teaching is as follows:

Practice of Medicine, Physical Diagnosis, Applied Therapeutics—Professor John J. Morrissey; instructors, Heinrich Stern and James F. Power. Daily clinics.

Surgery—Professors, Thomas H. Manley and Carl E. Pfister; associate professor, A. E. Isaacs and a corps of instructors and clinical assistants. Daily clinics.

Gynecology—Professor Augustin H. Goelet; associate professor, A. Ernest Gallant, with instructor and clinical assistants. Two clinics daily.

Pediatrics—Professor, S. Henry Dessau; instructor, Salo Cohn; clinical assistant, A. Trenchard Wood. Daily clinics.

Ophthalmology and Otology—Professors Marcus Kenyon and J. Albert Meek, and clinical assistants. Daily clinics.

Genito-urinary Diseases—Professor, Ferdinand C. Valentine and staff. Daily clinics.

Neurology and Mental Diseases—Professor, Thomas D. Crothers; associate professor, Louis Lichtschein; clinical assistant, J. L. Goodfried.

Professor T. D. Crothers will deliver a course of clinical lectures on drug diseases caused by alcohol, opium, cocaine, chloral, and other narcotics, their resulting psychoses and palsies, their diagnosis, prognosis, treatment and medico-legal bearings.

Rhinology and Laryngology—Associate Professor Max. J. Schwerd and staff. Daily clinics.

Dermatology and Syphilography—Instructors, Robert J. Devlin and W. R. J. Dalton. Daily clinics.

Special courses are also given, charged for by arrangement. A general ticket for four weeks costs $100, for eight weeks, $150. Separate courses are charged at proportionate rates.

CHICAGO.

In Chicago the opportunities for pursuing post-graduate studies under the most favorable circumstances are particularly good. There are four schools, two of them large ones, with well-arranged and equipped buildings, and, as a matter of course, there is a great quantity of clinical material.

The Chicago Polyclinic. This institution has been founded fourteen years, and has attained an excellent position. It is located in the heart of the city. Its own building contains a large hospital, and it is within easy reach of five others.

Only legally qualified physicians and graduates of reputable colleges are admitted.

The general ticket (not including matriculation) admitting to all courses and clinics, for four weeks, costs $60; for six weeks, $75; for two months, $90; and for three months, $110. The general ticket does not include the course of operative surgery on the cadaver, or the operative course in ophthalmology on the cadaver, both of which are extra. Special rates are made for courses of six months or a year.

The summer courses, from June 30 to September 15, are conducted by the associate professors and lecturers. The fees for all the courses are one-half the winter rates. Detailed plan of studies.

Surgery—There is a surgical clinic at the Polyclinic daily at 11 A.M., conducted by Professors Harris, Hoadley, Smith and Halstead. Professors Miller and Harris hold clinics at the Maurice Porter Hospital. Professor Senn holds two surgical clinics weekly throughout the year, on Tuesdays and Thursdays, at 2 P.M., at the Presbyterian Hospital. He also holds clinics for the students of the Polyclinic at St. Joseph's Hospital, Mondays and Wednesdays, at 9 A.M. Professor Henrotin gives clinics at the Alexian Brothers' Hospital from November 1 to May 1. Professor Van Hook holds a weekly surgical clinic at Cook County and Wesley hospitals.

Professors A. E. Hoadley and E. M. Smith give two clinics each week in orthopedic surgery.

Clinics are given in rectal surgery by Professor A. E. Halstead.

A daily clinic in diseases of women is held at the Polyclinic at 10 A.M. by Professors Henrotin, Newman, Bangs, Keyes, and Tyler, and by Professor fessors Lewis and Manierre at 3 P.M.

Daily clinical instruction in diseases of the eye is given by Professors Colburn, Wilder, Allport, and Mahoney, and Professors Fiske, Hall, and Shambaugh give a clinic each day on diseases of the ear.

A clinic in diseases of the nose and throat is held daily by Professors Brown, Dickerman, and Walther.

A clinic in general medicine is given daily at 2 P.M. at the Polyclinic, by Professors Patton, Favill, Fisher, and Preble; and other clinics are held during the week by Professor Fütterer and the other professors.

A clinic in skin and venereal diseases is held at 1 P.M. three times a week by Professors McArthur, Anthony, and Campbell.

Professor Belfield holds a clinic in genito-urinary diseases twice a week. Clinics in diseases of children are held daily at 8 A.M. by Professors Christopher, Churchill, and Houston.

Clinical instruction in diseases of the nervous system is given at the Polyclinic three times a week by Professors Patrick and Gill, and instruction in obstetrics is given twice a week at the Polyclinic.

The courses in pathology, bacteriology, clinical microscopy, and clinical chemistry are given under the personal supervision of professor Herzog, the director of the laboratory.

There is a training school for nurses in connection with the Polyclinic Hospital.

The Post-Graduate Medical School of Chicago.—This is situated in the medical center of the city, and is surrounded by a thickly populated district, from which is derived an almost unlimited supply of clinical material. Many of the large city hospitals are near at hand, and the Northwestern University Medical School is located just across the street. The school and hospital are contained in a large six-story building, furnished with all the latest appliances of science, as well as for the comfort and convenience of its students and patients.

The faculty is a large one, numbering among its members some of the prominent medical men of the city. A fee of $25 is charged for each clinical course of four weeks. Special rates are made to those who take longer courses than one term.

The daily clinical course continues throughout the year.

Clinics in diseases of the eye are held by Professor W. F. Coleman at 4 P.M. on Mondays, Wednesdays, and Fridays; by Professor Casey A. Wood, at 8.30 A.M. on Tuesdays and Saturdays; by Professor Woodruff at 8.30 A.M. on Mondays and Thursdays; by Dr. Huizinga on Wednesdays and Fridays at 8.30 A.M.

Clinics are held in diseases of the ear on Mondays, Wednesdays, and Fridays at 3 P.M., and on Tuesdays, Thursdays, and Saturdays by Professors Andrews and Pierce. Daily clinics are held in diseases of the nose and throat by Professors Hardie, Stein, Head, and Campbell.

Every Monday and Thursday a clinic in diseases of women is held by Professor Ries. Professor Martin gives clinics on Wednesdays and Saturdays; Professor Goldspohn on Tuesdays and Fridays; Professor Rumpf on Tuesdays and Fridays, and Professor McDiarmid on Mondays and Wednesdays.

At 10.30 every morning clinics in surgery are held at the school by Professors Ferguson, Beck, and Schaefer; at 4 P.M. on Tuesdays and Thursdays by Professor Eisendrath. On Mondays and Thursdays at 9 A.M. a clinic on orthopedic surgery is given by Professor Hardon.

Clinics in general medicine are held daily at 3 P.M. by Professors Elliott, Gentless, Mix, Monash, and Wells.

Professors Cook and Hardon give daily clinics in diseases of children.

Professors Brown and Kuh each hold two clinics a week at the school in nervous diseases.

Professors Baumand McMahon give daily clinics in venereal and skin diseases at the school from 2 to 3 P. M.

Professor Fenton B. Turck holds three clinics a week upon diseases of the stomach and intestines.

A course of urinary analysis is given three times a week by Professor A. R. Elliott and Dr. W. A. Jaquith. The fully-equipped *x*-ray laboratory is in charge of Dr. Gordon G. Burdick. Free clinics are given on Wednesday and Saturday mornings, between the hours of 10 and 12. The laboratory of pathology and bacteriology is under the direction of Dr. Robert Zeit, professor of clinical pathology and bacteriology at the Northwestern University Medical School of Chicago. The terms for the regular course are $25 a month. The department of anatomy and operative surgery is under the direction of Professor Raymond Custer Turck.

The Chicago Clinical School.—This purely post-graduate school is located in a large well-equipped building in the heart of the city, and consequently in a district where the facilities for pursuing clinical study at the best possible advantage are abundant. Fee for the general course, including matriculation fee and certificate of attendance, is $50 for four weeks; $65 for six weeks; $75 for eight weeks. These fees embrace everything in the following branches: internal medicine and physical diagnosis, major and minor surgery, orthopedic surgery, bacteriology and clinical microscopy, genitourinary surgery, gynecology, rectal diseases, electrotherapeutics, skin and venereal diseases, post-mortem technique, obstetrics, diseases of children, mental and nervous diseases, diseases of the eye, ear, nose, and throat, fluoroscopy and skiagraphy.

Also anatomical demonstrations on the cadaver and intestinal surgery on dogs; also intubation of the larynx and the mastoid operation on cadaver. Evening lectures are given by clinicians on special subjects desired by the students. The general course includes everything except the two special demonstrations above mentioned.

Chicago Eye, Ear, Nose, and Throat College.—A post graduate school for practitioners of medicine is located in its own building two blocks from the court house. The building contains a large hospital for eye and ear cases only. The clinical material is abundant, and the courses are for one month. Students can enter at any time. The teaching is clinical and free beds are provided for charity cases.

PHILADELPHIA

Philadelphia has always been known as a center of instruction in medicine and surgery, and its medical men quickly recognized the need and value of after training for medical graduates. The Polyclinic of Philadelphia is one of the most complete and best arranged of such schools in the world.

The Philadelphia Polyclinic.—This was organized in 1882, and was opened for the purpose of teaching in 1883. It is equipped in the most modern manner throughout, and besides the large number of patients treated in its wards during the past year there were upward of 23,000 new cases treated in its dispensaries. The faculty of the college represents the staffs of almost all the large hospitals of the city.

The regular winter session extends from October 1 to June 15, and the following is the schedule of prices for work during that period. Tickets are issued for courses of six weeks, of three months, of six months, or of one year. Tickets can be procured for a shorter time than six weeks by special arrangement. A general ticket for one week costs $20. The fee for the general ticket for six weeks is $90, for three months, $150, and for six months, $250. A general ticket for one year costs $350. The fees for separate clinical courses are relatively reasonable, and it is possible to take a combination of courses at a cheaper rate.

The faculty are as follows: I. Solis-Cohen, emeritus professor of diseases of the throat; Charles H. Burnett, emeritus professor of diseases of the ear; C. B. Vanerede, emeritus professor of general and orthopedic surgery; George C. Harlan, emeritus professor of diseases of the eye; J. Henry C. Simes, emeritus professor of genitourinary surgery; Arthur Van Harlingen, emeritus professor of diseases of the skin; H. Augustus Wilson, emeritus professor of orthopedic surgery; Edward Jacobson and Samuel D. Risley, emeritus professors of diseases of the eye; Henry Leffmann, emeritus professor of clinical chemistry and hygiene; Charles K. Mills, emeritus professor of diseases of the nervous system. There are also many other professors, including such well-known names as Drs. Solomon Solis-Cohen, Edward P. Davis, J. M. Baldy, and Augustus A. Esher.

The course consists of surgery, genitourinary surgery, diseases of the rectum, orthopedic surgery, diseases of the eye, diseases of the ear, diseases of the nose and throat, diseases of the nervous system, general medicine, applied therapeutics and physical diagnosis, diseases of the stomach and intestine, obstetrics and diseases of infancy, diseases of children, diseases of the skin, diseases of women, defects of speech, and practical instruction in massage. All of these branches are taught in a practical manner.

A distinctive feature of the Philadelphia Polyclinic is its laboratories under the direction of Dr. B. M. Randolph, who is also dean of the college. These laboratories are situated immediately in the rear of the hospital, and occupy a five-story brick building especially designed and constructed for the purpose. They are fitted up with all the modern scientific apparatus and are designed for the completion of diagnosis of cases which occur in the hospital and the careful and rapid examination of specimens sent by practising physicians for diagnosis. They are also intended for the pursuit of scientific research under favorable circumstances and for the instruction of students in the routine of laboratory work.

From June 15 to October 1 all clinical courses at the Polyclinic are given at a reduction of 25 per cent from the regular schedule of prices. This reduction is made because some of the professors take their vacations during this time. The number of patients attending the dispensaries is greatest during the summer. The regular schedule of clinics is followed and, in the absence of professors, clinics are in charge of capable and experienced instructors.

NEW ORLEANS

New Orleans, the largest city in the southern part of the United States, is fittingly provided with an excellent post graduate school. The supply of clinical material is large, and the school has, since its establishment, in every way justified its existence.

The New Orleans Polyclinic. This school was opened in 1887, and in 1895 the school was housed in a new building. The Polyclinic is in proximity to and has free access to the wards of the Charity Hospital, an institution of 750 beds, while the Milliken Memorial Hospital for Children is located on the same grounds with the Charity Hospital and is equally accessible.

The Polyclinic itself, at the corner of Tulane avenue and Liberty street, is a well constructed building, equipped with all modern and scientific medical improvements. A general ticket, including seventeen branches in medicine and surgery, costs $100 for six weeks and $75 for four weeks, while single tickets may be had for $15 and $12, respectively; when two or more courses are taken the charge is $12 each course for six weeks and $10 for four weeks.

Plan of Instruction.—Clinics are held in general clinical and operative surgery, including orthopedics, applied anatomy, minor and clinical surgery, diseases of the nervous system, diseases of the eye, diseases of the ear, nose and throat, dental and oral surgery, genitourinary and rectal diseases, obstetrics and gynecology, clinical gynecology, diseases of children, general clinical medicine, diseases of the skin, clinical microscopy and bacteriology, diseases of the digestive apparatus, clinical therapeutics, and clinical diagnosis. The session opens the first week in November and closes at the end of May.

Dr. Charles Chaissagnac is the President of the Polyclinic, Dr. P. E. Archinard, Vice-President, and Dr. Isadore Dyer, Secretary and Treasurer. The faculty consists of Professor Rudolph Matas, emeritus professor of surgery; A. W. de Roaldes, emeritus professor of diseases of the ear, nose, and throat; F. W. Parham, general clinical and operative surgery, P. E. Archinard, diseases of the nervous system; Henry Dickson Bruns, diseases of the eye; A. G. Friedrichs, dental and oral surgery; Charles Chassaignac, genitourinary and rectal diseases; P. Michinard, obstetrics and gynecology; T. S. Kennedy, diseases of children; G. Farrar Patton, clinical medicine; Isadore Dyer, diseases of the skin; E. Denègre Martin, minor and clinical surgery; J. J. Archinard, clinical microscopy and bacteriology; J. A. Storck, diseases of the digestive apparatus; Felix A. Larue, operative surgery and applied anatomy, G. M. Dupaquier, clinical therapeutics; H. C. Cocram, clinical gynecology; Otto Lerch, clinical diagnosis; Gordon King, diseases of the ear, nose, and throat; E. A. Robin, diseases of the eye. There is, in addition, a large corps of lecturers and clinical assistants.

POST-GRADUATE INSTRUCTION IN UNDERGRADUATE SCHOOLS.

In addition to the regular post-graduate schools, many of the schools of medicine in the United States give post-graduate instruction.

Johns Hopkins University has, since the inception of the medical school proper, given courses for graduates in the months of May and June.

Medical Department of Harvard University.—Courses of instruction are offered for graduates of recognized medical schools, and during the present year these have been given in subjects embracing all the branches of practical and scientific medicine. The extensive laboratories of the school are in every way excellent, and the clinical advantages afforded by the hospitals of Boston are unsurpassed.

Jefferson Medical College and Hospital, Philadelphia.—Graduates in medicine desiring to take the senior course, without being candidates for the degree and therefore without examination, may do so and will receive a certificate of attendance.

The Michigan College of Medicine and Surgery, situated at Detroit, has established a practitioner's course. The work of the practitioner's course is so arranged that physicians may enter it at any time and leave it when they think best. The teaching is made thoroughly practical in the following branches: Surgery, practice of medicine, obstetrics, gynecology, diseases of children, diseases of the nervous system, venereal diseases, diseases of the skin, laryngology, ophthalmology, otology, and thoracic diseases. There is no examination in the practitioners' course. The instruction is largely practical, and consists more in training the student in methods than in precepts. The fees for the post-graduate course are, for all subjects, $50; single subject, $25.

Louisville Medical College.—Graduates of this college, or of other schools desiring to pursue a post-graduate course, will be charged a fee of $25, and given a certificate attesting time spent in such work.

At the Hospital College of Medicine, Louisville, the Medical Department of the Central University of Kentucky, special provisions are made in the arrangement of clinical and laboratory studies for practitioners of medicine. This course embraces the subjects usually taught in post-graduate courses.

The Kentucky School of Medicine and Hospital at Louisville also gives a post-graduate course, for which the fee is $25.

Several other schools of medicine in the United States also provide opportunities for the pursuit of post-graduate work.

Argon and Other Gases of the Air.—Ramsay and Travers have isolated five new gases in the air, namely, helium, neon, argon, krypton and xenon, and have determined their constants. The periodic law of Mendeleft is thus written by them:

Hydrogen, 1; helium, 4; lithium, 7; glucinium, 9; fluorine, 19; neon, 20; sodium, 23; magnesium, 24; chlorine 35.5; argon, 40; potassium, 39; calcium, 40; bromine, 80; krypton, 82; rubidinum, 85; strontium, 87; iodine, 127; xenon, 128; cæsium, 133; barium, 137.

Open Street Cars.—Summer has come with sudden onset, and the supply of open cars in the streets falls far short of the demand. In the rawest, chilliest, and most disagreeable days of spring there were too many of these cars. Now there are too few. The management of the lines is sometimes strangely capricious.—*New York Tribune.*

CERTAIN CLINICAL TYPES OF BRAIN SYPHILIS[*]

By PEARCE BAILEY, M.D.,
NEW YORK.

CONSULTING NEUROLOGIST, ST. LUKE'S HOSPITAL; INSTRUCTOR IN NEUROLOGY, COLUMBIA UNIVERSITY.

I FEEL that an apology is due the president and members of this society for bringing to their attention so well-worn a text as syphilis of the brain. Since the appearance of Heubner's monograph in 1873 the subject has been on a solid basis, both clinical and pathological; and subsequent contributions, while they have widened our knowledge, have not materially changed its foundations. Light on this question, to be really new, can only be shed when bacteriology or chemical pathology answers the riddle of how this unforgiving disease transmits and perpetuates itself. Until that day comes, those of us who are practising physicians must be content with perfecting our clinical experience.

It may be that my own interest leads me to overestimate its importance, but I have long felt that an intimate and every-day familiarity with brain syphilis was, perhaps, the most essential qualification of a neurologist. My apology, therefore, for asking attention to so old a theme is the frequency, variability and urgent need of recognition of the disease. In its frequency alone there is justification. In and about centers of dense population direct syphilitic lesions form a long chapter in cerebral pathology. In my records of private cases brain syphilis has been three times more frequent than sciatica, and in about the same ratio to progressive muscular atrophy and paralysis agitans. It has been more frequent also, though in less proportion, than infantile spinal palsy. In fact, with the exception of general paresis and locomotor ataxia, brain syphilis is, perhaps, the commonest organic lesion seen by the practicing neurologist.

Great as is its variability in symptoms and in course, and diverse as it may be in its onset, there is often one set of more or less distinctive symptoms which dominate the picture at first, and which may or may not continue to do so. Thus in some cases a poplectic seizures, with paralysis, which come, which go, which come again, constitute the type of the disease. In others, recurring headaches; and in still others, Jacksonian or idiopathic epileptic attacks. As the disease progresses, if the lesions in the brain become more diffuse and more diversified, the symptoms are multiplied, and the above-mentioned clinical types lose their individuality. On the other hand, the recurrence, from time to time, of the initial symptoms may remain as the single clinical expression of the brain affection.

It would, of course, be futile, to attempt to separate too sharply these cases into symptomatic groups; or to insist on clinical restrictions for a disease whose possibilities are unrestricted. To modify an aphorism of Ricords: "*Une syphilis commencée Dien le sait où-élle finira.*" An apparently insignificant palsy of one ocular muscle may at any moment be overwhelmed by an apoplectic stroke; or symptoms indicating one type of lesion may quickly be changed to those of another type. Nevertheless, it is useful to group these cases in accordance with their initial symptoms for purposes of closer observation, and also because the initial symptoms sometimes remain the type of the disease throughout.

The most important clinical groups of brain syphilis are the apoplectic, the epileptic, the meningitic, those characterized by isolated oculomotor palsies and those characterized by meningeal symptoms which correspond with the anatomical types of gummata and cerebrospinal affections. It is not my purpose to attempt to describe any of these types in detail. Such descriptions can be found in text-books. But I wish to speak of some variations from the customary ones and also to discuss the effect of trauma as a cause of them, and of neuroses and psychoses as results of them. The types characterized by gummata and by isolated oculomotor palsies are so well recognized, and well described generally, that they may be passed over without mention. The only thing also to be said here about acute specific meningitis is the possibility of its course being wholly changed by the addition of apoplexy. This was the case in an observation published some years ago in conjunction with Dr. G. E. Brewer. The patient had been suffering some time with intense headache, slight optic neuritis and the general symptoms of syphilitic meningitis. The prognosis seemed favorable. But the disease suddenly changed in type from meningitic to apoplectic and the patient died. The autopsy showed a basilar meningitis to which had been added thrombosis of the basilar and cerebellar arteries.

---

[*] Read before the Baltimore Neurological Society.

The commonest group of brain syphilis and the one in which the symptoms are most varied, is that from lesions in the blood vessels. I shall, therefore, begin here.

Vascular Cases.—The acute apoplectic seizures of cerebral syphilis are so frequent, and generally so well recognized that they may be passed over with brief mention. My experience with them has been in most points in accord with the classic descriptions of the books. It has seemed to me, however, that cutaneous disturbances of sensibility have been rather more common than is usually described, and disturbances of the higher visual tracts distinctly more so. A large number of the cases of permanent homonymous hemianopsia that have come under my observation have been of luetic origin. This statement applies to cases in which the symptoms clearly indicate the lesion to be supra-basal, and of vascular origin; it does not include the defects in the visual fields caused by pressure, at the base, upon the peripheral optic tracts. In the following case of ingravescent apoplexy, the visual disturbances were the chief objective signs. A man, syphilitic for several years, after having felt nervous and upset for a few days, woke up in the middle of the night with a feeling of nausea and a terrific pain in the right occipital region. The next day he noticed that vision for objects on his left side was impaired. Examination showed a distinct left homonymous impairment of vision without paralysis or other focal symptoms. Promptly put under treatment this symptom disappeared almost entirely in three weeks.

In some vascular cases, focal signs are wholly absent. The following case illustrates such a state of things. It is reported with some hesitancy, as no history of syphilis was obtained, and as the symptoms were not unmistakably those of syphilis. The patient, however, had led a life of questionable circumspection, and was only forty years of age. For several days before the attack, she had been feeling rather tired and nervous. The attack heralded itself by a sudden severe pain in the occipital region. This pain was described as so excruciating, that the patient was practically out of her mind for the half hour it lasted. It was followed by nausea, vomiting and dizziness, and general severe headache. The patient was confused for several hours after the severe pain. The physical examination was negative except that the knee-jerks were rather active and the patient was tremulous and nervous. Under the iodide these symptoms gradually passed away, though it was several weeks before the patient recovered sufficiently from the nervous shock to leave the house.

In contrast to these cases of acute vascular disease are those in which the symptoms develop slowly, taking weeks or months, or even longer to become characteristic or even recognizable. At first they are chiefly mental. The friends of the patient notice a change in his disposition. He becomes irritable, inattentive and forgetful. Headache is usually not a prominent symptom. Disturbances of special brain functions are late in appearing. When they finally appear, they are often not pronounced, existing as a difference in the deep reflexes of the two sides, or as pupillary inequalities, or as slight hemiplegia, or, in fact, as almost any one of the localizing evidences of brain disease. In the early stages these cases have the appearance of some idiopathic mental disturbance; later they often resemble brain tumor (gumma), though the general symptoms of brain tumor are absent and there is no optic neuritis. These cases have, in my experience, responded very poorly to specific treatment. One reason may be that the diagnosis is not made early enough, so that when treatment is finally applied, the organic products have passed the stage when they can be reabsorbed. The two following cases, one with autopsy, are excellent examples of this condition.

A gentleman of fifty, with the history of syphilis fifteen years before, gave the first evidences of brain involvement three months before his death. The earliest signs were eccentricities in behavior and a change in character. A man of large business interests and great activity, he became inattentive and forgetful, lost interest in his affairs, managed them ill and neglected them. He became morose and irritable and complained somewhat of headache. These symptoms, which in some ways strongly resembled those of incipient general paresis, had existed for about two months, when he came to New York for treatment. None of the physical symptoms of general paresis were present. The pupils were equal and reacted normally; the knee-jerks were equal and active, there was no tremor of the face. The patient became continuously worse. The mental enfeeblement progressed, and there soon developed symptoms suggestive of sensory aphasia. When spoken to, the patient would give entirely irrelevant answers, as though he either had not understood, or had misunderstood what was said. The general mental hebetude prevented satisfactory inquiry into the speech disorder. A few days before death there appeared slight signs of right hemiplegia. The sensibility on the right side was diminished; the patient used the right arm and leg less than the left, and the right knee-jerk became more active than the left. There was never an optic neuritis. On autopsy the whole left temporo-sphenoidal lobe was somewhat increased in size and softened. There was no general atheroma of the cerebral vessels, and except for the condition mentioned the brain was macroscopically normal. Microscopical examination showed the lesion in the temporo-sphenoidal lobe to consist of endarteritis of the small arteries; innumerable foci of round cell exudation, some immediately around the arterioles, and some apparently free, all very small; and scattered areas of softening. These findings agree very well with the clinical symptoms if we can assume that the lesion was only adequate to cause the definite local symptoms observed in the last few days of life, when softening had been added to the endarteritis and miliary gummata.

The second case referred to is so similiar to the one just described that although not substantiated by autopsy, it can be placed in the same category. A gentleman, sixty years of age, having had syphilis twenty years previously, became troublesome in a hotel in August, 1901. Generally of a quiet disposition, fond of hunting, fishing, etc., his character changed completely in two or three days, and he became extremely obnoxious to the other guests in the hotel. He made obscene remarks in public, became boisterous and unruly, would catch hold of ladies ankles as they sat on the piazza, and altogether behaved so extravagantly that every one thought him insane. Within a week of the onset of these symptoms he was brought to New York, where, in less than a month, he died. When he arrived in New York, where I first saw him, he was completely demented. He did not answer the simplest questions, and made little or no effort to speak. The urine and oftentimes the feces were passed involuntarily. The physical signs of general paresis were absent. The pupils were equal and reacted normally, the knee-jerks were normal, there was no tremor about the face or lips. The only focal signs consisted in an increased rigidity in the right arm and right leg, and a diminution in sensibility on the right side of the body. These became quite pronounced a few days before death. He died in coma.

In both these cases energetic specific treatment was entirely ineffectual. In the latter, the symptoms and course of the disease seemed aggravated by it.

In another class of cases the development of the symptoms is much slower and the symptoms themselves are general, rather than focal. They indicate a diffuse involvement of the cerebral arteries. Most conspicuous among them are slight hebetude, inattention and failure of memory. Dizziness is fairly constant. The knee-jerks are active, and speech is often somewhat thick, and sometimes there is slight uncertainty in gait. These cases usually terminate by an apoplectic stroke, but often do not do so until the preceding symptoms have existed for years. The patients illustrative of this group whom I have seen have been between forty and fifty years, with the history of syphilis many years before. Specific treatment has been unavailing. It may well be that these cases are not true examples of syphilis, but that cerebral endarteritis was only hastened by the venereal disease.

Cases Characterized by Somnolence.—Somnolence is a frequent and characteristic sign of brain syphilis, whatever the anatomical type of the disease may be. Oftentimes, it goes hand in hand with the other symptoms, improving as they improve, or deepening into coma as the disease increases. Cases are on record in which somnolence, deepening into coma, has ended in death without other symptoms. Oppenheim especially has emphasized the clinical importance of this particular variety of mental affection as a herald of attacks, or as an isolated symptom. He says that the condition imitates normal sleep, not only in its general characteristics, but also in the way the patient disposes the limbs and responds to stimulation. When awaked, he goes to sleep again. Reports of such cases are not numerous in the literature, although Oppenheim says he has seen several. He regards them as of serious prognosis. Keyes has also mentioned these cases as particularly liable to occur after exposure to great heat. The following case illustrates a mild grade of the condition, from which there was perfect recovery. The patient was thirty-five years of age when he contracted syphilis in 1894. He was treated systematically for two years. In the spring of 1898 he was in the South, where the heat was intense. All the time he was there he was lazy and heavy, feeling very sleepy most of the time. He was unable to perform his work satisfactorily, and returned to New York in July. He there gained fifteen or twenty pounds of flesh, which made him distinctly overweight. When seen by me in October, 1898, these symptoms were practically unchanged. He still felt lazy and sleepy and without activity. He could do his work, but it required great effort. His recollecting power was good, but he was very forgetful through inattention. For example, he frequently rode past his station on the elevated, forgot to come to meals, etc. This was a distinct change from his previous habits. The patient took little interest in the examination. Seemed sleepy and apathetic, and while his case was being discussed he sat with eyes covered with the hands.

The only physical signs demonstrable were a slight weakness in the left leg and slight increase in the knee jerk on the left side. The patient was put on an energetic course of inunctions and iodides, and cleared up in every way in six weeks. Since that time he has had occasional courses of the iodide. But the only subsequent symptom at all suggestive of specific trouble was an enlargement of one pupil, which probably came on suddenly. This pupil returned to its normal size in about two months, under treatment.

Cases Characterized by Attacks.—Under this heading it is intended to include cases of epileptoid character.

Every case of brain syphilis may at some time or another have an attack consisting of a sudden increase of existing symptoms or a sudden development of new symptoms. Such attacks may herald hemiplegia or aphasia; they may change the course of a meningitis—they may cause death. Under these conditions the attack marks a distinct epoch in the disease. The cases I wish to speak of now differ from the preceding in that the attacks are the main feature of the malady, recurring with a certain regularity and not being followed, for a time at least, by other symptoms. This group is an extremely important one. The cases which go to form it are numerous and are not infrequently mistaken for epilepsy of other origin. In the larger number of cases the symptoms are focal or Jacksonian. Then they are as varied as brain functions themselves. Aphasia, either motor or sensory, dysarthria, hemianopsia, and other temporary disturbances of vision; one sided tingling and numbness or even partial anæsthesia; convulsive movements of a few muscles or of groups of muscles; or dizziness or petit mal, with its amnæsias and other equivalents of temporary mental unbalancement. All of these, and countless variations of them, may exist, without remarkable variation or sequelæ for weeks or months, or even years. Once begun as recurring attacks they are apt to be very frequent, occurring several times a week or every day or many times a day. They may follow a true epileptoid course for a long time, though ultimately they are complicated by an extension of symptoms. The following case offers a fair example of this condition. The attacks were cut short by specific treatment.

The patient, a stenographer, forty-one years of age, referred to me by Dr. E. L. Keyes, Jr., contracted syphilis in 1881. Treated systematically for three years. In 1897 he had an attack of partial hemiplegia, from which he recovered perfectly in three months. In the spring of 1901, he began to have feelings of numbness in the tongue, then down the right side, then down the left side. These would come and last a minute or two, and then disappear without leaving any after effects whatever. These attacks stopped independently of treatment. On September 14 they began again, and lasted until the 23d, the date of my examination. During these nine days the attacks were very frequent, there being ten or eleven of them daily. All affected the right side with sensations of tingling and numbness. There was no twitching of muscles, but motion was nevertheless affected. For example, the patient was walking when one attack came on. He had to sit down as the right leg became unruly and ataxic, although not paralyzed. There was no disturbance of speech either as motor or sensory aphasia. But there was agraphia, as in one attack the patient was writing and had to stop. He could hold the pen and make strokes with it, but could not form the characters. He had slight headache during the attacks, but no dizziness. The longest attack lasted three minutes. In no attack was there disturbance of consciousness. The attacks left no sequelæ and he felt well between them. The physical examination was absolutely negative. Under mixed treatment the patient made a perfect recovery. In this case the absence of both physical and mental signs of paresis, the fact that the attacks only occurred in series with intervals of perfect health, and their disappearance under treatment, led to the diagnosis of syphilis as opposed to paresis.

The pathological explanation of these Jacksonian attacks is in the great majority of cases, to be found in diseases of the blood vessels. They may also result from local gummatous growths from the bone, from the meninges or in the brain itself.

General epileptic attacks, identical with the seizures of idiopathic epilepsy are also observed in persons who have had syphilis. They form a considerable proportion of the cases of "late epilepsy" or epilepsy developing in adult life. In the great majority of cases they are due to generalized intracranial disease, either of a vascular or productive character. In many cases, the physical evidences of such disease are at once apparent on examination of the patient, showing themselves chiefly as symptoms of descending degeneration in the pyramidal tracts. In other cases, the attacks are the unique initial evidences. After a longer or shorter time, there may develop evidences of focal lesions. In still other cases no such signs ever develop, and the question arises, is the epilepsy really due to the syphilitic poison? This question discussed at length, would lead to too long a controversy for this paper. Answered briefly, it may be said that it is the consensus of opinion that the general epilepsy of syphilitics is in the majority of cases due to specific and histologically definable disease in intracranial structures and that such disease may be, but oftener is not, influenced by treatment. In some cases there are no evidences of specific disease other than the fits. In the latter it is supposed that syphilis acts as one of many causes and the epilepsy connot be distinguished from ordinary idiopathic epilepsy. The one exception to this is as follows: Fournier describes epileptic attacks as occurring during the second or florid stage of syphilis. He believes that they depend solely upon the action of the syphilis toxins on the ganglion cells of the cortex; and that they tend either spontaneously, or by treatment, to recover. These cases must be very rare, most authors being unfamiliar with them.

The epileptic equivalents are rarely mentioned as symptoms of syphilis. Such a case has, however, been described by Bechterew (*Revue Neurologique*, 1897, No. 1).

The patient (probably) became syphilitic at age of fifteen. At the age of twenty-seven, he began to have headaches with nocturnal exacerbations over the frontal and parietal regions. Then came short periods of disturbed consciousness followed in a few weeks by genuine periods of automatism during which the patient tore up banknotes, went away from home and was lost, etc. Examination now showed slightly enlarged and painful areas on both sides of the skull. After two weeks of treatment with the iodide and inunctions, the swelling and pain disappeared and the attacks of automatism ceased.

Any post-syphilitic affection characterized by recurring attacks immediately suggests general paresis, and the diagnosis between paresis and brain syphilis characterized by attacks, is frequently difficult and often enough impossible. When either the physical or mental signs of paresis are pronounced, or unmistakable symptoms of syphilis are present, differentiation should cause no great embarrassment. But in default of these latter, and in view of the fact that the initial symptoms of paresis may be limited to grand or petit mal seizures, to transitory periods of dizziness or of unconsciousness, or of paralysis, and that such manifestations may exist as unique symptoms for months or years, it is readily apparent how difficult the problem may be. In themselves the attacks of paresis may be identical with those of brain syphilis, so that the only means of differentiation are the associated symptoms and the course which the disease follows.

In the following case the youth of the patient, the short-time interval between the acquisition of syphilis and the development of cerebral symptoms and the absence of all mental symptoms, speak for syphilis rather than paresis, yet absolutely positive diagnosis appears to me impossible. A young man, twenty-two years of age, referred to me by Dr. Chetwood, contracted syphilis two and a half years ago. From that time until the present he has been under systematic treatment with mercury and the iodides. His first cerebral accident occurred about eighteen months after the chancre. It consisted in a severe attack of dizziness. Three months later there came on, gradually, a partial palsy of the right leg, which slowly passed off again. A similar attack came shortly afterwards. Recently he had two attacks, with only a week's interval. One of them consisted in partial hemianopsia, with tingling in the right half of the face and in the right hand; the other, in hemianopsia only. Both lasted about half an hour. Aside from these attacks the patient is in fairly good health. No headache. No mental disturbances other than nervousness about himself. The pupils respond, and the knee-jerks are active. There is some tremor of lips, face and tongue. These symptoms were not checked by specific treatment.

In all cases, with the possible exception of Fournier's "syphilitic epilepsy," epileptiform attacks in persons who have had syphilis are extremely important symptoms. If due to general paresis, their significance is most gloomy. If due to brain disease, and they pass unrecognized and untreated, they will pretty surely eventuate in an apopletic seizure. If recognized, and vigorously treated, there is every hope that they will disappear without entailing further mischief. In this latter eventuality they will have served as d ger signals of service.

Syphilis and Trauma.—By Saenger (*Die Beurtheilung der Nervenerkrankungen nach Unfall*, Stuttgart, 1896), and others, syphilis as an important factor in predisposing to the traumatic neuroses has been duly emphasized. Whatever rôle it may play in the etiology of these baffling affections, in their symptomatology it plays none. From their clinical manifestations, or from their course, the preexistence of syphilis can neither be affirmed nor denied. It is not intended to speak of these disorders under the present heading, but rather of those in which syphilitics after definite traumatic injuries, develope nervous symptoms of characteristic type. The researches of Ehrnzooth (*Deut. Zeit. f. Nervenh.*, 1901) have demonstrated that local injuries to the nervous system create a *locus minoris resistentiæ* which facilitates the action of toxic principles. Thus two series of animals were injected with cultures of various pathogenic bacteria. The animals of one series had previously been subjected to slight injuries to the head. The injured animals showed a much lessened degree of resistance, both local and general, to the bacteria, than the uninjured ones. It would seem that these experiments would agree with the clinical relations between syphilis and trauma; that local brain injury would create a *locus minoris resistentiæ*, upon which the specific poison would act; and that trauma would occupy an important place in the etiology of brain syphilis. The earliest writers on syphilis of the nervous system have emphasized such a relationship. Yet, in the extremely voluminous literature of the syphilis question, there are but few instances recorded in which it is made plain. Much more has been written on the traumatic origin of tabes and paresis than upon that of syphilis of the brain; yet, on *a priori* grounds there is far greater reason to suppose that the former diseases are less often the unique results of injury than the latter. From a considerable experience with general traumatic injuries of the nervous system, and with syphilis of the nervous system, and from a careful overhauling of the literature bearing on this point, I have come to the conclusion that trauma as a direct excitant of brain syphilis is extremely rare. That it does sometimes so act, however, cannot be denied.

Nonne ("Syphilis and Nerven System," Berlin, 1902) reports a case of brain tumor and one of basal meningitis, both valuable in their etiological relations. In the first, a young woman, two years after infection and six weeks after a fall on the head, from which she was unconscious for an hour, developed symptoms of brain tumor. Remedies proving unavailing, operation was resorted to, and a gumma was found in the anterior central convolution. The second case, which was verified at autopsy, was that of a longshoreman who, with the history of syphilis three years previously, developed the symptoms of a progressive basal meningitis. These came on as a result of a fall which had caused a severe cerebral concussion.

The following case, for the early history of which I am indebted to Dr. Frederick Peterson, is the only one I have personally observed. A single man, thirty-five years of age, two years after contracting syphilis, for which he had received thorough and apparently effective treatment, was hit on the head with a mallet. He received a slight scalp wound, which just reached the periosteum. He was not rendered unconscious, and did not complain of headache. He developed, however, a condition of somnolence and inattention. He would lie in bed till the afternoon; he lost interest in things, and was more or less oblivious to his surroundings. About three weeks after the accident he suddenly developed a left facial palsy and the right pupil became larger than the left.

Under energetic specific treatment these focal symptoms and the great somnolence vanished, and during the five years the patient has been under observation no focal symptoms have reappeared, with the exception of slight sluggishness of the pupils. Mentally, however, the patient underwent a complete change from the first. Immediately after the accident, as has been said, somnolence and apathy were pronounced, which disappeared for a time under specific treatment. In the succeeding months, however, the patient became irritable and very erratic, and developed delusions of persecution. He finally threatened homicide against one particular person, who, he thought, had used him ill, so that it was necessary to have him committed to an institution. This idea of injury, which was an insane delusion, faded away with time, and the patient's liberty was restored to him. But he remained partly demented and to the present time has been entirely incapable of resuming his business. Specific treatment has proved, for the mental symptoms, entirely ineffectual. The absence of physical signs and the long persistence, without material change of the dementia, argue the diagnosis of cerebral syphilis, of which the immediate exciting cause was trauma.

Cerebrospinal Types.—Syphilis in its attacks upon the central nervous system has the tendency to make deposits, microscopic though they be, in both brain and spinal cord. It is probable that most, if not all, cases of nervous syphilis are cerebrospinal, anatomically. Clinically, the cerebrospinal character of the affection may or may not make itself apparent. In many cases the clinical type is exclusively cerebral or exclusively spinal; in others, while the conspicuous symptoms are cerebral, there are also symptoms pointing to spinal involvement; in still others with the spinal symptoms well in the foreground, there are also evidences of lesions in the brain. Thus a patient in whom the suggestive complaints and prominent objective symptoms indicate brain disease may also have the purely spinal symptoms of diminution or loss of one or both knee-jerks, or of slight retention of urine, or of pains or paræsthesiæ in definite peripheral nerve areas; or in so-called spinal syphilis, *e. g.* meningomyelitis, pseudo tabes, etc., careful examination often reveals irregularities or inequalities in the pupils, or an immobile pupil, or a paretic ocular muscle; or the patient may complain of headache in a way to make the existence of brain disease almost certain. These cases are well recognized and present only slight difficulties of diagnosis.

When, on the other hand, the symptoms are cerebrospinal from the beginning, the clinical picture is apt to be much more obscure. With a fairly acute course, and with pronounced symptoms as in a case of Oppenheim's (Die Syphilitischen Erkrankungen des Gehirns) the nature of the trouble is usually unmistakable. But in cases of slow development and rather uncertain symptomatology, error in diagnosis is easily possible, if not excusable. In some ways these cases resemble multiple sclerosis—in others, the signs are hardly definite enough to certainly put them out of the class of neurasthenia. The following is an example of the class of case referred to:

A. J., thirty-nine years of age, was referred to me in April, 1900, by Dr. E. L. Keyes. The patient had syphilis in 1887, which lasted, with intermissions and under treatment, for two years. There were no further recurrences until July, 1899. The following symptoms then developed: partial retention of urine, impotence, sensations of coldness in the legs and numbness in the feet, and slight ataxic difficulty in walking. No pains. Dizzy attacks came occasionally, and at one time the patient had difficulty in speaking for several days. Examination showed a slight static ataxia with normal knee-jerks. The pupils responded sluggishly to light. The left pupil was larger than the right, and there was perhaps a slight ptosis in the left eye. The patient has occasional attacks of dizziness. He complains also of general physical weakness and lack of energy. Specific treatment had failed to give any relief.

It was to call attention to this case [illegible] that the [illegible] group was mentioned in this paper. Such cases are beyond the ordinary range of differential diagnosis as laid down in the textbooks, and depend for their recognition upon the personal experience and thoroughness of the examiner. I am inclined to think that they are fairly frequent but often unrecognized.

Psychoses and Neuroses.—Before closing I wish to say one word of these conditions. Their relationship to syphilis is very hard to define. Maniacal and melancholic mental states of delusion and depression, emerging into dementia, are ordinary clinical occurrences of organic brain syphilis. They are symptomatic only. Theoretically, therefore, they should be differentiated from the purely functional states included under the terms psychoses and neuroses. Is such a differentiation possible? Is it possible to determine whether there is such a thing as a syphilitic melancholia or syphilitic neurasthenia existing as a pure functional disturbance of nerve cells without the gross syphilitic lesions in connective tissues? If so, can the diagnosis be made from the symptoms, and is the antisyphilitic the proper therapeutic method?

My personal experience would lead me to answer no to these questions. But there are a few, though very few, cases in literature which would seem to indicate that they might be answered in the affirmative. In considering such cases sight must not be lost of the variation in the personal equation of the observer or the possibility of the existence of vascular or meningeal affections, too slight to be recognized as such, yet sufficient to give a wide range to psychical disturbances. Certain it is that psychoses and neuroses, such as neurasthenia, hysteria, melancholia and dementia are disproportionately frequent in persons who have had syphilis. Neurasthenia is, by far, the most frequent of this group. In my private records, more than 25 per cent. of the male cases of non-traumatic neurasthenia have had syphilis. Of these a large number received active antisyphilitic treatment. It has always been a question in my mind if the toxic effects of treatment upon the nervous system were not in many cases as responsible as the venereal disease. I think we all have seen cases of diseases of the nervous system in which a syphilitic origin, while not probable, could not be absolutely denied, and in which, largely on speculation, vigorous mercurial treatment, and large doses of iodide, were instituted. It has been my experience in several such cases to see the patients get rapidly and progressively worse—more rapidly and more progressively than the natural course of the disease would have led one to expect. It has seemed to me under such circumstances that the toxic effects of these medicines gave a strong downward impetus, and consequently I have ceased believing that such treatment could "do no harm." An interesting case of such toxic effects is given by Kowalewsky (*Centralblatt für Nervenheilk. und Psych.*, March, 1893).

A soldier, healthy until the age of thirty-one, then contracts syphilis. Under mercury the symptoms quickly disappeared, but years later there were recurring cerebral attacks characterized by dizziness, headache, hemiplegia, etc. During three months the patient received sixty injunctions of one drachm each of mercurial ointment and large quantities of iodide. Toward the end of this time, and as the paretic symptoms were disappearing, the patient became very irritable, suspicious and fearful. He was afraid to be alone, afraid something was going to happen, was sleepless, restless and excitable. Thus although the evidences of organic disease were disappearing under the treatment, those of functional nature were appearing and getting worse. With the cessation of treatment the neurasthenic symptoms lessened and finally disappeared. In a succeeding attack the same phenomena occurred: the appearance of neurasthenia under specific treatment and its disappearance when the treatment was stopped. With such facts in view it is perfectly legitimate to inquire if syphilis is not sometimes made to bear the stigma of neurasthenia, when it really belongs to iodism and mercurialization. I fully believe it does. But I am more than ready to admit that syphilis and syphilis alone is responsible for many of the post-syphilitic neurasthenias. But in the vast majority of these the functional nervous disturbances result from the malnutrition brought about by the venereal disease, and the proper treatment consists in general tonic measures rather than in specific remedies. In a few cases, perhaps, the direct poison of syphilis is responsible. In these the symptoms will disappear under anti-syphilitic remedies.

The other neuroses and psychoses can be dismissed with brief mention. Epilepsy has already been spoken of. In the predisposing causes of hysteria, syphilis is commonly spoken of, especially by French authors. It has never been a reasonably probable cause in any cases which have come under my observation. Melancholic symptoms are common after syphilis. They frequently accompany the organic brain lesions and are prominent in the post-syphilitic neurasthenias. But I have not been able to find any well authenticated cases of the pure psychosis melancholia which were cured by antisyphilitic treatment. In mania, the differential diagnosis between organic lesion and psychosis is much more difficult. Berkeley ("Mental Diseases," New York, 1900) describes under Furibund delirium cases in which, after prodromal periods of headache, moroseness, etc., a mania of furious type develops, which lasts for days or weeks, and is succeeded by partial coma. The anatomical substratum of this condition is doubtful. It is probable that in most cases of syphilitic mania meningitis or vascular disease could be demonstrated.

Post-syphilitic dementia is in all probability due to vascular disease. In it, therefore, specific remedies are distinctly indicated, though, unfortunately, they are not always successful.

Helpful Galactose.—A hitherto unknown element in milk, a new ferment, has been discovered at this station, called galactose, which is proving of value in the ripening of cheese. The properties of this ferment are similar to the secretion of the pancreatic organ in the human body. Old cheese is a predigested food, and the digestion is wrought by the galactose. It was found that the galactose would go on working at very low temperatures—temperatures at which bacteria were practically inert. Cheese was put into refrigerators and kept frozen for months. Other cheese was kept just above the freezing point. It was found that the finest cheese is cured at from 40° to 45° F. Practical cheese manufacturers had maintained that 50° was the lowest temperature at which cheese could be worked without becoming bitter and worthless. The new discovery will, it is believed, revolutionize cheese manufacture, doing away with all curing rooms, the cheese being sent directly to the refrigerators.—*W. S. Harwood in Scribner's Magazine.*

MULTIPLE NEURITIS.*

By DANIEL R. BROWER, M.D., LL.D.,
CHICAGO.
PROFESSOR OF MENTAL AND NERVOUS DISEASES, RUSH MEDICAL COLLEGE.

The diagnosis of multiple neuritis in its classical form is a very simple proposition, but at the bedside there are few classical cases, so that in this disease, as in many others, errors in diagnosis are not infrequent; as the prognosis of multiple neuritis is usually favorable under proper treatment, and the prognosis of the diseases with which it is usually confounded is very bad, a correct diagnosis is a matter of great importance. The disease is the result of some kind of poison and while the action of this agent may be limited to the peripheral portion of the neurons, yet there are cases in which the cell body as well is impaired, and this also makes confusion in diagnosis. The principal poisons producing a multiple peripheral neuritis are alcohol lead, arsenic, and the toxins of the various micro organisms, especially those that produce diphtheria, influenza, typhoid fever, gonorrhœa, syphilis, leprosy, and beriberi.

In the typical cases of multiple neuritis, we have a symmetrical localization of motor, sensory, and vasomotor symptoms. In earlier stages the symptoms are the result of irritation of the nerve, while the later symptoms are those of destruction. Thus we have in the beginning muscular cramps and spasms, shooting pains, and paresthesia. Later on, paralysis and anæsthesia. If all the cases were thus characterized, there would never be any difficulty in diagnosis, but, unfortunately, in some cases the motor phenomena dominate or stand alone; in other cases the sensory symptoms are equally prominent, and are associated with a very small amount of muscular weakness; while in still other cases the vasomotor phenomena eclipse the other symptoms. As examples of the distinctly motor type, we have lead paralysis, Landry's paralysis, and tetany. Of the sensory type, pseudotabes and leprosy. Of the vasomotor type, erythromelagia and Reynaud's disease.

The common form of multiple neuritis is that which has its etiology in alcoholism, and this ordinarily presents to us the mixed type, the type in which the motor, sensory, and vasomotor parts are each more or less involved. The diagnosis of alcoholic neuritis will be based upon the evidences of chronic alcoholic poisoning, found in the digestive, circulatory and nervous systems. The onset is usually insidious, weeks or months being necessary for its full development; the earlier symptoms are numbness, tingling, muscular cramps and tremors, and vasomotor disturbances, such as either cold and clammy hands or feet, or a hot and burning sensation in the same extremities. Progression of the disease is characterized by more intense pains by nerve and muscular tenderness to pressure, followed by cutaneous anæsthesia, and we have frequently this anæsthesia with muscular hyperesthesia. The paralysis soon results in a quadriplegia, with foot and wrist-drop. In the earlier stages knee-jerk is often exaggerated, and there is hyperextension of the great toes, but these soon disappear, and patellar reflex is lost and the toes become flexed. With paralysis there is a progressive atrophy; the muscles soon lose, in pronounced cases, reaction to faradism, and they require strong interrupted galvanic currents to produce contraction. The very early appearance of these electrical reactions make a valuable aid to the differentiation of multiple neuritis from anterior poliomyelitis, in which latter disease these electrical reactions are established only after a much greater interval of time. The escape of the muscles of the trunk in all the ordinary cases, and the control the patient has over the sphincters, of the bladder and rectum, are valuable aids in differentiation from myelitis.

In a few cases there is a very marked psychic disturbance, which may be either in the way of exaltation or depression, both alike accompanied with marked failure in memory. These psychic symptoms are probably as much a part of the general alcoholism as they are of the special manifestations of the neuritis.

Arsenical neuritis—which is rare—very much resembles the alcoholic form. The differentiation from alcoholic neuritis was made in the few cases I have seen by the absence of all evidences of alcoholism, by the œdema of the eyelids, pigmentation, the epigastric pain and nausea. These cases were the result of the continued use of large doses of Fowler's solution; in them the tremors were more marked than in alcoholic neuritis, and the knee-jerks and superficial reflexes were present. Some cases are the result of a combined action of alcohol and arsenic, as witness the remarkable epidemic from beer that occurred in Manchester, Eng., in 1900, (*Journal American Medical Association*, January 26, 1901). Another good example of the mixed type of multiple neuritis is beriberi, and the intimate association which the country now has with the Oriental peoples, where this disease is by no means uncommon, makes it quite necessary for the physician to be familiar with its general aspect. It is a specific form, the precise poison producing it is still in doubt. Recent investigation by Ross (*British Medical Journal*, February 8, 1902) would seem to indicate that arsenic may be the principal etiological factor, although hitherto this has been regarded as microbic. It is characterized by œdema of connective tissue, effusion in the serous cavities, the special liability to implication of the phrenic and pneumogastric nerves. There is usually a prodromal stage of several days or weeks, with general malaise, depression of spirits, headache, numbness, stiffness, cramps of legs, œdema of the ankles, diarrhœa, and usually a slight fever. These symptoms sometimes come on with great rapidity, the patient going to bed well, and waking up in the morning unable to walk or stand. The œdema of the legs increases, the hands and the face become puffy, the paralysis develops, knee-jerks are abolished, palpitation and cardiac dyspnœa become marked, and the urine is much diminished. After a variable space of time the renal secretion becomes abundant, the œdema disappears, and the legs and arms undergo a marked atrophy.

An example of the motor type of neuritis is found in lead palsy, of which there are two common types, characterized, the one by the lower arm symptoms (wrist-drop), and the other, not so common, the upper arm type. Lead as an etiologic factor in producing disturbances of the nervous system is a much more common one than many suppose. In cities like Chicago, where in the homes of many of our citizens the water supply is some part of the day deficient, the pipes, in fact, may be empty of water, and then become encrusted with oxide of lead. As the increased pressure fills up the pipes again, and water is drawn, particles of lead are detached and pass into the drinking vessel, an thus enter the bodies of the patients, and while we have in the blue line on the gums, when present, an excellent means of differentiation, yet we have many cases of lead poisoning in which this blue line is absent.

---

*Read before the Tri-State Medical Society, April 3, 1902.

Another example of the motor type of neuritis is Landry's paralysis. This disease in its typical form has sensation intact and sphincters uninvolved. The rapid advancing paralysis, beginning in the legs and extending upward, presents such a striking clinical picture that an error in diagnosis is rarely possible. In the slowly progressing cases there may be great doubt for a time, and especially in such cases in which there is numbness and some pain and paresthesia, still greater difficulty will be experienced in making a diagnosis.

Another form of the motor type of neuritis is tetany, and the one in which there should be but little difficulty in differentiation. The irritability of the nerves to the electrical current and to pressure, and the easy development of the spasms of the hands and feet by pressure and percussion over nerve trunks make such a picture that can rarely be mistaken for any other disease. A good example of the vasomotor type of multiple neuritis and one, in my experience by no means uncommon, is erythromelalgia. Sensory symptoms are here present sometimes to a very marked degree, but it must be by the redness of the skin of the feet that the diagnosis is made. It is a neuritis that is usually limited to the plantar nerve, and is multiple in that it usually involves both feet.

Treatment.—The treatment of these several forms of neuritis have, in common, rest, the relief of pain and insomnia, the use, in the early stages, of the constant galvanic current of low amperage applied daily to the nerve trunks involved, attention to elimination by skin, bowels, and kidneys. The several etiological factors give indications of treatment, the alcoholic require the bromides, with codeine in such doses as necessary to secure a reasonable degree of comfort, and the use of nerve tonics, of which strychnia is the most serviceable. In alcoholic neuritis it is absolutely necessary to withdraw at once and entirely the alcoholic stimulants. In the treatment of beri beri, it is the opinion of the physicians who have had much experience with the disease, that the patient must be removed from the locality where the disease was contracted, must have absolute rest in bed, mild laxatives, diuretics, tonics, and anodynes. When cardiac failure seems imminent, strychnia and nitroglycerine have given the best results.

After the acute stage of these several forms of multiple neuritis has passed, the patients all alike require vigorous restorative treatment. The hemoglobinometer will show the most of them to be markedly anæmic, and to relieve this, of course some preparation of iron must be used. My experience with the various recent preparations of iron has not in the least diminished my confidence in Blaud's mass, which received at the hands of Niemeyer, so many years ago, such warm endorsement. With iron may be combined quinine. The diet throughout the case must be carefully regulated to suit the digestive condition of the patient. They all need a very liberal diet, but it must be carefully proportioned to their capacity, so as to avoid a possibility of autointoxication by the gastrointestinal tract. So soon as the acute pain has disappeared the use of the galvanic current of a proper amperage, interrupted so as to produce muscular contraction, is indicated. The seances should be short, not more than three or four contractions of each group of muscles by a current of the least possible amperage should be made daily. This exercise of the atrophied muscles will ordinarily result in their slow development, and after a time they will respond to the faradic current and then it should be substituted. Gentle massage should be commenced at the same time the electrical exercise of the muscles begins, and the severity of this treatment should be increased as the muscular soreness subsides. There is nothing mysterious about massage, and any one of ordinary intelligence can soon be taught to do it properly. Much benefit may be had by the hypodermic use of strychnine, a daily injection beginning with one-sixtieth and gradually increasing it to a full physiological dose. If the case does not yield, hypodermic injections of the chloride of gold and sodium, gr. 1/24, may be added to the daily treatment. So soon as advisable the patient must be encouraged to make voluntary muscular movements frequently and to the utmost extent possible. Many of these cases of multiple neuritis in the beginning of the treatment are very discouraging, and the physician is apt to give them up as hopeless too soon. Some of the most satisfactory results that I have obtained have been in cases of long-standing neuritis, abandoned by physicians as incurable.

The Technique of the Widal Reaction.—[illegible] Fletcher recommends the following method, which ensures uniformity of results, requires a minimum amount of serum, and involves but little risk in manipulation. The blood is collected in U-shaped capillary tubes of glass having an outside diameter of about 2 mm. One end of the tube is touched to the drop exuding from a small incision in the tip of the ear and is quickly filled by capillarity, after which both ends are closed with sealing wax. In the laboratory the tube is placed in the centrifuge, and a stroke of the file serves to separate the serum-filled portion of the tube from that containing the clot. A fine pipette graduated in one-hundredths is held point up and the contents of the tube transferred to it again, which is easily effected by capillarity. The amount of serum in the pipette is read off and then blown into a test tube containing 1 c.c. of physiological salt solution. This mixture is further diluted by exactly the amount required to make a dilution of 1:10. The dilution is continued by putting ½ c.c. of salt solution into several test tubes, the first of which is allowed to remain empty. One-half c.c. of the 1:10 dilution is placed in tubes one and two, one-half c.c. out of tube two is placed in tube three, and one-half c.c. of this mixture in tube four. Each tube then contains one-half c.c. of diluted serum in strengths of 1:10, 1:20, 1:40, etc., five dilutions being usually made and one tube being filled only with salt solution as a control. Each tube then receives one-half c.c. of a typhoid bouillon culture which after one day of growth is killed by the addition of 1 per cent. of formalin, and has been allowed to settle for two days at a temperature of 37° C. The tubes now contain equal quantities of fluid and of culture and differ only by the amount of serum present, the dilution of which is now, of course, doubled. The tubes are immediately emptied into small glass dishes which are placed one on top of the other, and put in the thermostat to be examined at the end of one and two hours. The inspection is made under the low power (50 diameters), and but little practice is required to recognize artefacts, and by considering all doubtful reactions negative consistent results are regularly obtained.—*Centralblatt für Bakt. Parasit. u. Infektionskrankheiten.*

Nobel Prizes.—According to an official statement recently issued, the endowment of the Nobel Foundation is about $7,500,000, and the value of each of the five prizes to be awarded at the close of the present year will be nearly $40,000.—*Scientific American Supplement.*

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHERS

WM. WOOD & CO., 51 Fifth Avenue.

New York, June 21, 1902.

BACTERIOLOGY AND PHTHISIS.

THE views of the majority of scientific and medical men with regard to the bacteriology of pulmonary tuberculosis and its importance have varied considerably.

The advance of bacteriology since its inception has been remarkable and startling, until at the present time the sole aim of medical science would seem to be the discovery of disease-producing bacilli. There are, however, signs that a certain change of front as to the supreme consequence of microbes in causing disease is taking place, and many medical men are beginning to ask themselves whether the power of germs in this respect have not been overestimated.

At the American Congress of Tuberculosis, which met at the Hotel Majestic, New York city, on June 2, 3, and 4, the disposition to regard with a somewhat more lenient eye than formerly the reputed evil influence of microorganisms in connection with consumption was much in evidence.

Dr. Edwin Lewis, Secretary of the committee, read a paper in the second day's discussion on "The Importance of Individual Predisposition in the Development of Tuberculosis, with Some Remarks on the Relation of Metabolism to Human Susceptibility."

In the course of his remarks Dr. Lewis said that, in spite of the influence of Koch's discoveries on all discussion of tuberculosis, the specific treatment of the disease was no further advanced than it was twenty years ago, partly due, perhaps, to the reliance upon laboratory research more than on independent and clinical work.

It is a certain fact, the speaker went on to say, "that while at least 50 per cent. of mankind are susceptible to the bacillus of tuberculosis, only 14 per cent. really die from its harmful effects. . . . The meagre results of the struggle with this disease show that valuable time has been lost in directing energy toward the extinction of the tubercle bacillus. In other words, the patient had been neglected, and important changes in his mental economy had been overlooked too much for his good and for the advancement of medical science."

Dr. Lewis gave the following as his conclusions:

1. Individual predisposition is a far more important factor in the development of clinical tuberculosis than bacterial infection *per se*.

2. The constancy of a pronounced failure in metabolistic equilibrium, during and preceding clinical tuberculosis, points to its importance as the constituting factor of individual predisposition.

3. The study of ferments in physiologic processes shows that the enzymes are the working elements in the maintenance of normal metabolism, and justifies the conclusion that conditions of malnutrition are the result of their absence, decrease, or variation.

4. Study of the chemistry and biology of the bacillus tuberculosis and the conditions favoring and resulting from its growth in the animal body points to the fact that it possesses certain ferments in its organism which, under favorable conditions, perform the functions common to organic life.

5. Immunity to tuberculosis may be considered as the result and complement of those metabolistic changes in living tissue whereby the enzymes, through greater potency than those of the bacillus tuberculosis, are able to maintain a normal osmotic and functional activity in the ultimate cells.

6. Susceptibility to tuberculosis may be considered as a negative condition of organic tissue, whereby enzymes are less potent in the maintenance of normal osmotic and functional activity of component cells than those of the tubercle bacillus in establishing bacteriogenesis.

Dr. W. Howship Dickinson, Consulting Physician to St. George's Hospital and to the Hospital for Sick Children, London, delivered, a few weeks ago, a lecture, in which he made an eloquent protest against the popular conception of and the craze for bacteriology.

He said, in part, "The pathology of the present day is, above all things, bacteriological. It inclines to attribute all diseases with which bacteria have been associated simply and singly to a bacterial origin, confidently assumes that where microbes have not been found they will be, and sanguinely trusts that when found they will submit to control with a tractability in the future which our experience gives us no good warrant to expect. The other day I read in the *Lancet* of a bacillus of fatigue, and should hear, without astonishment, of bacilli of political or theological bias impelling their bearers to toryism or radicalism, scepticism or credulity. We see in tuberculosis, most obviously when it affects the lungs, the assured influence, in the first place, of general ill health and, in the second place, the scarcely less assured influence of local inflammation. The microorganism, though the primary cause, is of secondary importance. The implantation of the organism, as is clinically indicated, and, it may be added, pathologically demonstrated, in connection with inflamed tissue or inflammatory products, shows pulmonary consumption, in the beginning, at least, as a local disease, due to local causes. What we have to consider is not the bacillus, but the reception afforded it. It is not so much a question of the seed as the soil.

Such considerations gain practical value when we have regard to the ill-success which has hitherto attended attempts to cure phthisis by direct attack upon the bacillus; in other words, by the inhalation of germicides, could we kill the parasite we might expect to arrest the disease, though we should still have to deal with the injuries already inflicted. But the difficulty is to kill the guest, without hurting the host. The microorganism appears more difficult to destroy than the tissue among which it lies."

The commonest, practical and only really efficient measure of successfully treating consumption as yet known is by means of pure dry air and by feeding the victim with a sufficiency of nourishing wholesome food. To call such methods curative is perhaps something of a misnomer; they are not actually curative, but they do not aggravate the inflammatory symptoms, and by letting nature work, tend to build up the system, so that it is frequently enabled to throw off the burden of disease.

Nowadays the personal factor is too much disregarded; the microbe is looked upon as the "*fons et origo*" of the mischief, and all efforts are exerted to compass its destruction, while the human being is too lightly considered.

As Dr. Hutchinson truly remarks: "In the contest between the man and the microbe it is more to the purpose to back the man than to attack the microbe."

YELLOW FEVER IN EUROPE.

The Yellow Fever Institute of the United States Marine Hospital Service has just published a bulletin on yellow fever in France, Italy, Great Britain and Austria and the bibliography of yellow fever in Europe, compiled by Dr. J. M. Eager, Passed Assistant Surgeon M. H. S.

The first reliable account of the importation of yellow fever into France relates that the disease was brought to Brest by a squadron of men-o'-war from Santo Domingo.

The American ship *Columbia* also arrived at Marseilles in 18[illegible] with yellow fever aboard.

In 1821 an epidemic of yellow fever occurred in Spain and several persons suffering from the malady were conveyed by sea to the port of Marseilles. In 1839 a ship with numerous cases of yellow fever aboard entered Brest.

In the year 1861 there occurred at Saint Nazaire the only important epidemic of yellow fever that ever broke out in France. In an article on mosquitos and yellow fever, published in Paris last year, DeGouved concludes that the epidemic of Saint Nazaire, so carefully observed and recorded by Melier, was determined by mosquitos infected at Havana and transmitted to France in the hold of a ship. In this article on mosquitos and yellow fever, published October 12, 1901, in *Le Bulletin Medical*, Paris, DeGouved says:

In our opinion, all the facts of the case adapt themselves in a perfect fashion to the theory of the propagation of yellow fever by mosquitos. We may assume at the outset that during the loading of a suspected vessel at Havana a certain number of mosquitos, previously infected by sucking the blood of yellow-fever patients living in the near neighborhood, could enter the vessel's hold filled with cases of sugar and many stalks of sugar cane placed as a filling in the angular places of stowage to hold the cases in place and prevent friction. The stalks could have furnished the mosquitos with the necessary nourishment during the voyage.

During the broiling calms that followed for five days after the departure of the vessel from Havana the mosquitos excited by the heat of the atmospheres of the hold could very easily pass the defective bulkhead that separated the hold from the lodgment of a certain number of the crew and installing themselves in that place, sting the sailors, and thus inoculate them with the germs of the disease. All the other cases of infection are explained very simply since they all occurred in individuals who had been for a longer or shorter time in the hold of the vessel or in individuals who, like the sailors of the other vessels, had been down the hold from the infected ship. With all the cases of yellow fever that occurred at Saint Nazaire and Montoir the malady was not propagated by any of the effects of the crew taken with them to their families nor by the ship's cargo sent directly to Nantes by the railroad.

The history of the two epidemics in Italy assumed to have been yellow fever, namely, those at Leghorn in 1804 and at Torre Annunziata in 1833, are of interest, says Dr. Eager, because of the heated discussions that arose as to the diagnosis and the strenuous opposition that was made against branding the infected communities with the name of yellow fever, conditions recalling the story of many an epidemic that has prevailed in various localities in the United States.

The question as to whether the epidemics in Italy were yellow fever or not has never been definitely made clear. The medical men disputed vigorously on the point, and the majority in the end decided against the disease being named yellow fever. Those who went so far as to diagnose stated that icteroid typhus and infective fever characterized by jaundice were the maladies by which the sick persons had been attacked.

Since 1883, although it has been a frequent occurrence in Italian ports to have vessels arrive from South American ports with a history of yellow fever on board during the voyage, no cases have been registered ashore. In Great Britain in 1817, in 1852, in 1857, in 1864 and in 1865 vessels have arrived with cases of yellow fever aboard, but no cases have been reported ashore.

The history of yellow fever in Europe concludes with two deaths from the disease in hospital in Trieste, Austria. Two of the crew of an Italian ship which arrived at Genoa went by land to Trieste, where they were stricken by yellow fever and died in hospital. There is no record of an extension of the disease.

The interesting part of Dr. Eager's narrative to American readers will be the apparent confirmation of the findings of the United States Army Commission on Yellow Fever at Havana, afforded by the epidemic of the disease at Saint Nazaire, France, in 1861. Dr. Gouved brings a strong case against the mosquitos as carriers of infection in his account of the said epidemic.

POST-GRADUATE INSTRUCTION.

In the present issue of the Medical Record a very complete account is given of the post-graduate schools, and of the other means of post-graduate instruction provided in Germany and Austria and in Great Britain, in order to supply American graduates who may be thinking of taking supplementary courses abroad with information as to the resources of the medical centers of Europe in this respect.

If those who have taken a degree in this country are desirous of placing the coping stone upon their medical education by studying in foreign schools, no more suitable centers could be chosen than Berlin and Vienna, with their magnificent clinics. London, too, with its vast, almost unlimited wealth of clinical material, offers a rich field to the searcher after practical knowledge, and in addition possesses the great advantage to the American medical man that the language of the country is his own. At the same time the fact might be borne in mind that America was long before England in recognizing the value of the German and Austrian Polykliniks, and that she has improved upon her models. At the present time the large post-graduate clinics of the United States are conducted on a more systematic plan than those on the European continent, and are not, as there, scattered in various buildings with no regular method. The saving of time rendered possible by the American arrangement is obvious, and makes the post-graduate institutions of this country equal to any in the world.

The need, nay the necessity, in most instances of after-training for the medical man under existing circumstances, is freely a knowledged on all hands. Post-graduate institutions provide the necessary opportunities to study the practical part of the profession, denied to the majority while students. With the increase of knowledge of medical science, and especially of bacteriology, the curriculum of the medical student has been made so full, not to say overflowing, that the burden on the youth of average ability is too great for him to think of spending time on matters that do not directly concern the gaining of his degree. All his energies are bent upon passing his examinations as creditably as possible, the natural consequence being that, as a rule, when qualified, the young physician or surgeon is in no way fitted forthwith to commence practice, and if he intends to take up a specialty, or to proceed with research work, after-training is absolutely imperative.

These remarks apply particularly to America, where in many parts the medical course is still painfully brief, while nowhere is it so long as in Great Britain or on the continent. The amount of medical lore that a student of the average medical school of this country is expected to cram into his brain is alarming, and accentuates the need of efficient post-graduate instruction. As to whether it is wise to include in the medical curriculum such a bewildering multiplicity of subjects, as is now the case, is an open question. No less an authority than Huxley entered an eloquent protest against the practice. Nevertheless, we have to deal here with things as they are, not as they might or should be.

It may be said then that a course of instruction in foreign medical schools will have the effect of widening a man's mind not only so far as medical subjects are concerned, but in all those matters which pertain to a liberal education. But the individual who cannot afford, or perhaps does not wish to leave his own country, may console himself with the conviction that he might go farther and fare worse.

The account given in this number of the means afforded for post-graduate education in the United States will clearly demonstrate the fact that these are abundant, and that in many respects the system in vogue here is unsurpassed. There is, however, it must be confessed, one branch of post-graduate education in which Great Britain is not only superior to America, but easily leads the world. Reference is had to instruction in tropical diseases. The opinion has been expressed many times in the MEDICAL RECORD that a school of tropical medicine should be established in this country. The United States has within her own borders sub-tropical districts, and is, besides, the owner of tropical islands. It need hardly be said that special study is required by the physician who would know and treat properly the diseases incidental to hot climates. But this necessary knowledge cannot be had unless generous opportunities are provided for instruction.

THE EFFECT OF WAR UPON THE BIRTH AND DEATH RATE.

War not only influences the mortality of the army in the field, but has a maleficent effect on the birth rate and death rate of the country which is fighting. A low birth rate may be explained, to some extent, by the fact that when a nation is at war, her people at home are less prosperous, and, consequently, marriages are not so frequent.

The increase of the death rate occurs, probably, for the reason that food is scarcer, and also because at a time when a country is engaged in a disastrous war, the minds of its inhabitants are adversely affected. Those who are in delicate health, or who are attacked with sickness succumb much more readily when the spirits are low, than when in a normal condition It is, indeed, the reaction of the mind upon the body.

The returns of the Registrar-General of Great Britain of births, marriages, and deaths for the year 1900 demonstrate the potency of the influence of war upon the birth and death rate

The births in 1900 numbered 927,062, or a rate of 28.7 per 1,000, this being the lowest on record and 1.3 per cent., under the mean rate of the past decade. The illegitimate birth rate was also the lowest on record.

There were 587,830 deaths, or 18.2 per 1,000, as against 17, 17.4, and 17.5 in the previous three years. The number of deaths directly due to alcoholism was 3,683, while the death rate from this cause was 132 males and 95 females per 1,900,000. These rates constitute a highest on record. Tuberculosis claimed 61,302 victims, or a death rate of 10.4 per cent of the deaths from all causes. The death rate of the army was 27.6 per 1,000, as compared with 10, 12 and 10.5 in the preceding three years. The mortality rate in the army abroad was 36.1 per 1,000, as compared with an average of 14.5 in the past five years, and the death rate at home was 8.2, as compared with an average of 4.3 in the previous five years.

Thus it will be seen that war drains the life blood of a nation. Nothing is said in the above returns as to the action war is asserted to have on the production of sex. On the authority of German scientists, it has been declared that the females of a nation at war are apt to give birth to a much larger number of males than is ordinarily the case.

WAR ON MOSQUITOS ON LONG ISLAND.

The Long Island North Shore Improvement Association, through its Executive Committee, undertook a survey for the purpose of mapping the breeding places and habitats of the mosquito with the intention of initiating an active campaign against this pest during the coming summer. The committee has also published a small book giving the reports of the engineers and entomologists who made the survey, with the recommendations for the treatment of the breeding places revealed by the examination.

According to the New York Sun, the preliminary examination was made under the direction of Henry Clay Weeks, the engineer who, associated with Dr. L. O. Howard, Chief of the Division of Entomology of the United States Department of Agriculture, had charge of the work for Mr. Matheson at Lloyd's Neck, Cold Spring Harbor, last summer.

Professor N. S. Shaler, dean of the Lawrence Scientific School of Harvard University, was retained to make a special examination of the salt marshes and there were associated with Mr. Weeks as entomologists Professor Charles B. Davenport, professor of entomology at the University of Chicago, and F. E. Lutz, an instructor in biology at the same institution.

The territory examined is about seventy-five square miles in extent. Professor Davenport and Mr. Lutz walked over the whole district, examining the ponds and streams, and even the artificial receptacles of water, which might be the breeding places of mosquitos.

When their detailed reports had been turned in to Mr. Weeks, the engineer and his assistants went over all the places indicated and examined them with a view to recommending measures to be taken to get rid of the pest.

The seven kinds of relief measures recommended in the report are as follows: First—Many of the useless accumulations of water will be removed entirely, either by filling or draining. Second—The salt marshes will be handled; the problem here is to drain them, or to keep them covered with salt water, or to treat them so that there will be no accumulations of brackish water between high tides. Third—To prevent the breeding of mosquitos in the streams by straightening the banks and so regulating their courses, that there will be no pools of stagnant or slowly moving water. Fourth—To prevent the breeding of mosquitos in springs, by confining these to definite banks and by draining or filling springy areas. Fifth—The breeding in ponds and bodies of water which cannot be drained or filled, can be largely prevented by making the edges of the pond regular and freeing them from vegetation, so that there are no accumulations of water so shallow that they are not accessible to fish. The maintenance of certain kinds of fish in ponds so treated would probably entirely prevent breeding, or at least prevent them from breeding to any serious extent. Sixth—To carefully cover barrels and tanks and to tightly cover cisterns with the additional precaution of keeping a few fish in the latter. Lastly, cesspools, drains and catch basins should be kept tightly covered, and petroleum should be used also.

The estimated cost of the proposed undertaking is $141,000.

It is satisfactory to observe that in many parts of the United States determined efforts are to be made to exterminate or, at any rate, to diminish the mosquito pest. That much may be done in this direction has been clearly shown in the case of Havana, where mosquitos have been practically banished from the city itself and its immediate vicinity. The most radical, albeit the most expensive measure, is doubtless the most permanent and effective, namely, draining; but where it is impossible to do this, the other methods recommended by the experts in Long Island will serve to mitigate the mosquito plague.

CANCER RESEARCH.

The quest of the origin of cancer bids fair to be fervently followed by scientists of various nationalities. Germany for some time has been making investigations into the causation of the disease, in a systematic manner, but then state-aided laboratory workers in Germany enjoy facilities for research denied to those of other nations. The United States has of late made a considerable amount of progress in scientific research, especially with regard to cancer at the Buffalo State Laboratory—thanks to the munificence of private individuals. Undoubtedly, too, when all the splendidly endowed laboratories in different parts of the country have been fully equipped, some striking results may be confidently anticipated.

In Great Britain a forward movement with the object of probing the mysteries of cancer is at the present time taking place. The scheme of a combined cancer research first suggested by the London *Practitioner* would now appear to be on the road to realization.

The fund asked for ($500,000)—by no means an excessive one—will, it is said, be raised without much difficulty, but whether it will be sufficient or not remains to be proved. The plan proposed is that a Committee chosen by the foremost medical bodies shall supervise the investigations.

The *Practitioner* and *Hospital*, both fear that the machinery will be too complicated. Research by a committee, says the *Practitioner*, would not seem incongruous in a Gilbertian opera.

"It may be taken as certain that however carefully the Committees are selected, the superior person will be in the ascendant and the superior person has been, and by the law of his nature must be, the greatest obstacle to medical progress.

The *Hospital* remarks that the ordinary history of scientific discovery is that it has been the result of the patient industry of some single worker, who in most cases has been sustained against failure, or even against ridicule and obloquy, by his own intense conviction of the gleams of light, by which he was endeavoring to guide his steps.

The view taken is that a committee of worthy commonplace men would probably kill all originality, and, with supreme self-confidence would proceed on the even tenor of their way along the lines already mapped out, and would frown upon any deviation from the beaten path.

It is to be sincerely hoped—at any rate in this country—that the greater part of the magnificent sums donated to the cause of scientific research will not be expended in elaborate and ornate buildings. A simple building, furnished with all the necessary apparatus, will answer the purpose equally as well as a splendid imposing structure. After all, it is workers themselves who count, and they should not be stinted and starved as they too often are.

It may be said that, on the whole, the outlook for the discovery of the origin of cancer is more hopeful than ever before.

THE RETIREMENT OF SURGEON-GENERAL STERNBERG.

The estimation in which Surgeon-General George M. Sternberg, U. S. Army, just retired for age, is held by the members of his corps and the leaders of the profession of the country at large, is evidenced by the complimentary dinners given him in Washington on May 28, and in New York on June 13. To be thus honored falls to the lot of few, and it must be very pleasant to General Sternberg to feel that at the close of his official career his scientific and military efforts have been pronounced good by those best qualified to pass judgment on their merits. His recent retirement, after forty-one years of most varied service as a practising surgeon, sanitarian, and executive, marks the close of a period of medical progress unequalled in the history of the Army Medical Department. Three times brevetted for gallantry in action, a recognized authority the world over on sanitary matters, the wise and able head of his department through the trying period of the wars with Spain, in the Philippines, and in China, his retirement from active service is a distinct loss to his corps and country. The value of his services to the army, the nation, and humanity will long be remembered. General Sternberg enters upon his well-earned rest with the respect, affection, and good wishes of all with whom he came in contact.

FOOD IN THE TROPICS.

There is no entirely decided agreement among those who are entitled to speak with authority as to the kind of food most suited to the white man dwelling in the tropics. Major Seaman has insisted that but a comparatively small quantity of flesh food is necessary to sustain the physical vigor of the American soldier in the Philippines. Captain Munson holds, that while so large an amount of meat as is consumed by the soldier in temperate climates is superfluous and even hurtful to the health, yet that a certain substantial meat ration is needful. Others again assert that the meat allowance should not be curtailed, but, on the other hand, perhaps, increased.

A writer in the *American Journal of Military Surgery* for May referring to the subject of food in the tropics, says the ration as issued and cooked in this country is not suitable for the soldier in the tropics, and this has been demonstrated by experience, and by a board of officers and by scientific deduction.

It may be taken that Captain Munson's view of the food question as regards the soldier in the tropics is, probably, nearer the truth than any other which has been brought forward. The subject of diet in the tropics is one of infinitely great importance, indeed of the very first moment The digestive system of the white man residing in these climes suffers on account of sedentary habits, intermittent fever, unsuitable food and bad cooking. Decomposing food, too, is a fruitful source of liver derangements. Meat must be eaten shortly after the animal has been killed, or unless there are facilities for preserving it in refrigerators—the meat will quickly become tainted.

Dr. Harford-Battersby, writing in *Climate*, May, gives some useful hints with regard to the food most fitting for a white man in tropical countries.

He believes that concentrated essences are very useful in their place, but that one should not live principally on concentrated foods, or by disuse the digestive apparatus will be weakened. Fresh meat should be partaken of when procurable, and fowl. Fish is also a very valuable article of diet, but great care must be taken to ensure that the fish is fresh, as it very rapidly decomposes, and may be a source of serious risk.

The lack of vegetables is another great drawback in the tropics. There is much difficulty in obtaining an adequate supply of green food, although lettuces can be grown, whilst cabbages and some other green vegetables may be cultivated with more or less success. The potato will not grow in the tropics, but the yam is an excellent substitute, and the sweet potato can be obtained in many parts. Cassava is another most nourishing vegetable, and forms the staple of the diet of many native African races. Fruit, of course, is abundantly plentiful, headed by the succulent banana

Milk is usually difficult to procure, and there are portions of the tropics where it cannot be obtained. Another problem, hard of solution, is how to keep it sweet, as it naturally contaminates very easily. It would appear that the only method of temporarily preserving it is by sterilization.

Cereals, the chief of which is corn, are the mainstay of tropical climates.

It may be assumed then as a generally accepted fact that a white man in the tropics is unable to live and thrive on the same food upon which the natives exist, but requires a mixed diet with a certain quantity of meat, a good supply of vegetables and a larger amount of saccharine matter than he is accustomed to eat when living in the temperate zone

His greatest care, however, must be to abstain from alcoholic beverages. If a newcomer drinks even moderately he, undoubtedly, runs great risks, and it may be said without fear of contradiction, that indulgence in alcohol has ruined the health of more white men than any one cause. Total abstinence is the surest way to preserve one's health in tropical countries

---

Motor Ambulances for Paris—Paris, like London, is beginning to appreciate the fact that horse and hand ambulances are behind the times and travel far too slowly to give an injured person an opportunity of being treated promptly, and thus of being afforded a fair chance of recovery. The Paris correspondent of the *Lancet* says that complaints have several times been made with respect to the slowness of the ambulance vehicles belonging to the city, for they are drawn by only one horse, which is not always a fast goer. The question of the speedy arrival of the vehicle at the scene of an accident being of the first importance, it would at least be desirable for it to have two horses. Another thing is that the harnessing of the horses takes time. It would be very much quicker and more practical to use motor vehicles now that they are sufficiently speedy and trustworthy. For the daily removal of military patients special tram-cars are used, but even these are far from perfect. The idea of letting them run on the tramway lines is an excellent one, for it makes the journey both easier and quicker, but it is a mistake to use old vehicles, and it would be a good thing if the military tram-cars, which are no longer serviceable, were sent back to the car-builders, for those which are at present running in Paris have a deplorable appearance, and this service is, in several respects, open to improvements.

Electric Light on the Eyes.—A Russian specialist has decided that, contrary to the general opinion, electric light plays less havoc with the eyes than other forms of artificial light. He bases his deductions on the fact that disease and damage to the eye are proportioned to the frequency of the closure of the lids. He found that the lids close in a minute 6.8 times with candle light, 2.8 times with gas light, 2.2 times with sun light and 1.8 times with electric light.

News of the Week.

The New Surgeon-General of the Army. Gen. William H. Forwood, who has succeeded Gen. Sternberg as surgeon-general of the Army, was born in Delaware in 1838 and was graduated in medicine at the University of Pennsylvania. He was appointed an assistant surgeon of the army in August, 1861. His service has been long and honorable, including the Civil War, Indian campaigns, the war with Spain, the insurrection in the Philippines and the expedition in China. His first service was as executive officer at the Seminary Hospital, Georgetown, D. C., at the outbreak of the Civil War, soon after which he went to the front and took part in many memorable battles and engagements, including Yorktown, Gaines' Mills, Malvern Hill, the Second Bull Run, Antietam, Gettysburg, and Brandy Station. He attended the wounded under fire many times, and the night after the battle of Gaines' Mills, assisted by two soldiers, he succeeded in passing through the enemy's lines and in bringing off an officer from a point on the field where he had fallen severely wounded during the day. He was later captured by the enemy, but succeeded in making his escape under a hot fire. His horse was killed under him at the battle of Fairfield, near Gettysburg, and at the battle of Brandy Station he was shot through the right breast, from the effects of which he had much trouble for many years. He was twice brevetted during the Civil War for "faithful and meritorious services."

He was the only medical officer at Fort Riley, Kansas, in the fall of 1866, when there was an epidemic of cholera with many deaths. During a leave of absence in the fall of 1870 he volunteered to nurse yellow fever patients at the quarantine station, near Philadelphia, Pa., and spent nearly the whole of his leave there, in order to gain experience with a disease which he had never before had an opportunity of seeing.

For many years after the Civil War Gen. Forwood served on the western frontier, taking part in the campaigns against Indians. He served as surgeon and naturalist to the exploring expeditions sent through Wyoming, Montana, and Idaho during the years 1881, 1882, and 1883. The President and Secretary of War were with the last one of these expeditions. From 1890 to 1898, he was attending surgeon at the Soldier's Home, Washington, D. C., and during the same period he was professor of military surgery at the Army Medical School and professor of surgical pathology at Georgetown University. He also had charge of the 1,000-bed military general hospital at Savannah, Ga., and the establishment of the great tent hospital at Montauk Point in 1898. From December, 1898, to January, 1901, he was chief surgeon of the Department of California, and since that time he has been assistant to Surgeon-General Sternberg, at the same time serving as president of the Army Medical School. He is a recognized authority on military surgery, and has written many articles on this subject for standard text-books.

Gen. Forwood was promoted captain in 1866, major in 1876, lieutenant-colonel in 1891 and colonel in 1897. At the time of his nomination to be surgeon-general he was the senior officer in the medical department of the Army. His tenure of office as surgeon-general will be short, as he will retire for age in September next.

A Discussion on Leprosy was held at a recent meeting of the Medico-Chirurgical Society of London, the special point discussed being the etiology of the disease. According to a report cabled to the New York Times, Dr. Hansen of Bergen maintained that leprosy was entirely contagious, and that to prove Hutchinson's theory it would be necessary to discover the bacillus of leprosy in the cured fish. He declared that the people of Norway were now eating more fish than ever before, yet leprosy was disappearing because of the strict segregation. He said that several Norwegian lepers had emigrated to the United States and that their descendants were nonleprous, which went to prove that leprosy was not hereditary, but simply contagious. Dr. Thin also supported the contagion theory. Mr. Jonathan Hutchinson, however, stoutly reiterated his belief, which he said had been strengthened by his recent researches in South Africa, that leprosy resulted from eating badly cured fish. He declared his faith that the leprous bacillus would soon be found in the fish, and he reasserted his reasons from his experience for not believing the disease to be contagious.

College of Physicians and Surgeons. At the commencement of Columbia University on June 11 the degree of M.D. was conferred on 144 graduates. The ten honor men were C. E. Webster, Jr., Seward Erdman, H. Von W. Schulte, A. M. Peppenheimer, Ralph M. Beach, William T. Bull, James Francis Rice, Austen Fox Riggs, Philip Bissell, and Henry W. Titus, the first three of whom received the first, second, and third Harsen prizes respectively. The Harsen prizes for clinical reports were awarded to J. F. Saphir, I. S. Hirsch, and E. A. Spitzka. The fellowships of the Alumni Association were awarded as follows: Fellow in Anatomy, Edward Anthony Spitzka; Fellows in Pathology, Hughes Dayton and Augustus B. Wadsworth. The Alumni Association Prize was awarded this year to Dr. George Alfred Lawrence. The Alonzo Clark Scholarship, established to promote the discovery of new facts in medical science, was given to Dr. Augustus Jerome Lartigau.

Corps of Summer Visiting Physicians. The Board of Health has appointed seventy-seven physicians who will make up the summer corps. Of these physicians forty-six are from this borough, twenty-four from Brooklyn, three from The Bronx, and two each from Richmond and Queens. The physicians appointed work during July, August and September, chiefly among the poor children. They receive $100 a month each. Nearly 80 per cent. of the physicians appointed will be made permanent medical school inspectors when they have finished with their duties on the summer corps.

The Seaside Hotel of St. John's Guild was opened for the reception of patients on Monday, June 16. Patients are sent to the hospital by the Staten Island Ferry, a nurse and orderly being in attendance on the 10 A.M. and 2.30 P.M. boats.

Navy Department, Bureau of Medicine and Surgery, Washington, D. C.—Changes in the medical corps of the navy, week ending June 14, 1902: June 7.—Surgeon J. W. Ross, retired, detached from duty under the War Department at the Hospital Las Animas, Havana, Cuba, and ordered home. June 12.—Assistant Surgeon E. M. Brown ordered to the Naval Hospital, Mare Island, Cal., for duty.

Examination for Coroner's Physician.—The Municipal Civil Service Commission announces that a competitive examination will be held on Monday, July 7, for the position of Coroner's Physician. Applications for this examination must be made to the Commission, at 346 Broadway, Manhattan, not later than Wednesday, July 2. Candidates must be duly authorized to practise medicine in the State of New York and must present their diplomas as evidence thereof. This marks an important change in the method of selection of these officers, the appointments having been made previously without competitive examination. The salary attached to the office in the Boroughs of Manhattan, Brooklyn, and The Bronx is $3,000 a year, and in the Boroughs of Queens and Richmond, $1,500 a year.

North Hudson Hospital.—At the annual meeting of the Board of Governors of the North Hudson Hospital, held June 9, 1902, the following were re-elected as the Medical Board: *Attending Surgeons*, Drs. Richard Schlemm, Louis E. Poole, A. J. Walscheid, and F. B. Stellwagon; *Attending Physicians*, Drs. E. E. De Groff, John T. Luck, J. J. Benson, and C. M. De Meritt; *Consulting Surgeons*, Drs. Frank D. Gray and Talbot R. Chambers; *Consulting Physicians*, Drs. John P. Henry and Geo. W. King.

College of Physicians of Philadelphia.—At a stated meeting, held June 4, Dr. George C. Harlan read a "Memoir of the late Dr. William F. Norris;" Drs. J. M. Anders and L. Napoleon Boston read a paper entitled "Bence-Jones Albumosuria, with Report of Three Cases and a Review of the Literature." In one of the cases there was evidently neoplastic bone disease, probably myelomata; in the second the symptoms were strongly suggestive of such disease; while in the third there was evidence of preexisting nephritis. Drs. David L. Edsall and Caspar W. Miller presented a communication entitled "A Study of Absorption, Metabolism and Intestinal Putrefaction in Two Cases Nourished Exclusively by the Rectum." It was demonstrated that rectal alimentation was entirely inadequate, only a portion of the nutrient enema being digested and absorbed, a large portion undergoing putrefaction under the influence of the bacteria present, as shown by the increase in the ethereal sulphates in the urine. Drs. Robert G. Le Conte and Morris J. Lewis presented a communication entitled "Infection of Ovarian Cyst During Typhoid Fever, with Report of Two Cases; Operation, Relapse, Recovery." Dr. Edward Jackson read a paper entitled "The Degree of Protrusion of the Eyes, with an Instrument for Its Measurement." The device consists of a bit of cardboard or other material with a concave aspect to be directed toward the orbits, and ruled on each side in such a manner that the projection of the cornea in front of the vertical plane of the orbits can be easily read. The instrument is useful in determining degrees of exopthalmos, enophthalmos, etc.

Bequests to Charitable Institutions.—By the will of the late Ferdinand J. Dreer, an antiquarian and a liberal patron of educational and charitable objects, of Philadelphia it is directed that at the expiration of ten years, or earlier if the surplus warrants, the residue of the surplus income be divided into fifty-six parts, to be distributed among thirteen institutions, including the following hospitals and homes: Hayes Mechanics' Home, ten parts; Home for Aged and Infirm Colored Persons, three parts; Frederick Douglas Hospital and Training School, three parts; Home of Industry for Discharged Prisoners, five parts; Southern Home for Destitute Children, five parts; Presbyterian Home for Widows and Single Women, two parts; Presbyterian Hospital, two parts; German Hospital, ten parts. The value of the estate is placed nominally at $200,000 and upward. Upon the death without issue of the testator's two sons, one-half of a trust fund of $200,000, created for their benefit, is to be distributed among twenty-two institutions, including the following hospitals and homes: Home for Incurables, Presbyterian Hospital, Jewish Hospital, Howard Hospital and Infirmary for Incurables, Presbyterian Orphanage, House of Industry for Discharged Prisoners, Southern Home for Destitute Children, Hospital of the Women's Homeopathic Association, Rush Hospital for Consumptives, St. Christopher's Hospital for Children, Orphans' Home and Asylum for the Aged and Infirm of the Evangelical Lutheran Church, and Hayes Mechanics' Home. The residuary estate is bequeathed to thirteen institutions, including the Hayes Mechanics' Home, Home for Aged and Infirm Colored Couples, Frederick Douglas Hospital and Training School, Home of Industry for Discharged Prisoners, Southern Home, Presbyterian Home, Presbyterian Hospital, German Hospital.

By the will of the late Valentine Geng of Upper Darby Township, Pa., bequests aggregating $36,000 are made as follows: St. Mary's Hospital, Philadelphia; Old Colored Folks Home, Pennsylvania Training School for Feeble-Minded Children, Presbyterian Hospital, Philadelphia; Baptist Orphanage, Angora; German Hospital, Philadelphia; Jewish Hospital, Philadelphia, each $5,000; Chester Hospital, $1,000.

Dr. A. Edward Davis has resigned from the medical staff of the Manhattan Eye and Ear Hospital.

The American Medical Association.—At the closing session of the American Medical Association in Saratoga, the recommendation of the House of Delegates to meet next year at Little Rock was rejected, and it was decided to meet at New Orleans in May, 1903.

A Dinner to Dr. Sternberg.—A complimentary dinner was given to ex-Surgeon-General George M Sternberg of the United States Army at Delmonico's on the evening of June 13 to give his colleagues in the medical profession an opportunity of expressing their appreciation of the work which the officer has done during his term of service. He was retired on the age limit on June 8. About one hundred physicians and surgeons of the country were present. several of them making addresses. The banquet was presided over by Dr. E. G. Janeway of this city.

An Alleged Cure for Diabetes.—The London correspondent of the *New York Times* cables to his journal that Dr. A. C. Faulds of Glasgow has discovered a remedy for diabetes in an infusion of dried eucalyptus leaves. He uses this in preference to the oil of eucalyptus, and says that his experiments were prompted by learning that the remedy was used by the natives of New Zealand. Of forty-six diabetic patients treated with eucalyptus, Dr. Faulds claims to have cured fifteen, or 33 per cent.

Obituary Notes.—Dr. Otis R. Freeman, who was believed to be the oldest practicing physician in America, died at his home in Freehold, N. J., on June 8, at the age of ninety-four years. He had been confined to the house for several weeks, but only five days before his death had set the fractured arm of a boy who called at his house for relief. Dr. Freeman was a graduate of the Medical Department of Dartmouth College in 1843. He served as surgeon during the Civil War, and on one occasion, he together with Dr. Lydy of Philadelphia, worked at the amputating table for fourteen hours without rest. While serving in the war he received an injury from which he never recovered.

Dr. George W. Woods, a retired medical director of the United States Navy, well known in army and [illegible] died in San Francisco. He was born in New Bedford, Mass., in 1838.

Dr. Stephen C. Russell, the oldest practising physician of New Orleans, died there June 11, aged eighty-three. He was a native of Yarmouth, Me., but studied medicine at the Tulane University, from which he was graduated in 1848. He went to California in the gold days and practised there and at Panama. Returning to New Orleans in 1851 he was active in the yellow fever epidemics of 1852, 1853 and 1858. He was for years Secretary of the Louisiana State Board of Health.

Dr. Edward N. Whittier died in Boston on June 14 after a brief illness. He was born in Gorham, Me., on July 2, 1841. He entered Brown University in 1858 and graduated in 1862. He served in many campaigns and battles with the Army of the Potomac. At the close of the war he went to Boston and entered the Harvard Medical School, graduating with the class of '66. He was an instructor at the Harvard Medical School for many years.

Dr. Cloyes W. Gleason died in Philadelphia on May 30 at the age of eighty-one years. He was a graduate of the medical department of the University of Pennsylvania and was the first professor of anatomy and physiology in the Woman's Medical College of Pennsylvania.

Dr. Thomas F. Corson, died in Philadelphia on May 28 at the age of sixty years. The Civil War breaking out while he was a student in the medical department of the University of Pennsylvania he enlisted and served as an assistant surgeon in the Sixty-seventh Pennsylvania Volunteers until the end of the war. When peace was declared he resumed the study of medicine and was graduated in 1866. He engaged in the practice of his profession for a time, but subsequently conducted a drug store, and eventually became a dealer in real estate. He was a cousin of the late distinguished Dr. Hiram Corson of Montgomery County.

Dr. Joseph Eastman of Indianapolis died on June 5 at the age of sixty years, from cancer of the liver. He was born in Fulton County, N. Y., in 1842. At the beginning of the Civil War he volunteered in one of the New York regiments, but was soon invalided by typhoid fever, and on his recovery was detailed to hospital duty. This turned his thoughts to medicine and, while still in the army, he studied at the Georgetown College, receiving a degree in 1865. He then immediately joined the medical corps and served as assistant surgeon of volunteers. After being mustered out he began practice in Indiana, but soon came to New York to take an additional medical course, and was graduated again at the Bellevue Hospital Medical College in 1870. A few years later he moved to Indianapolis, where he soon gained an enviable reputation as a gynecologist and abdominal surgeon.

Dr. Hallock R. Maine died at his home in Brooklyn on June 13 of pneumonia. He was born in 1865 and was graduated from the College of Physicians and Surgeons in this city in 1888. He was attending physician to the Kings County Hospital.

Dr. Selden H. Talcott, superintendent of the Homœopathic New York State Hospital at Middletown, died on June 14. He was a graduate of the New York Homœopathic Medical College in 1872, and in 1875 was appointed chief of staff of the Ward's Island Hospital. Two years later he was appointed superintendent of the Middletown State Hospital, and about a month ago a dinner was given to him in this city in commemoration of the close of his quarter century of service.

Correspondence.

OUR LONDON LETTER.

(From Our Special Correspondent.)

LONDON HOSPITAL—DR. WM. MILLER ORD'S DEATH—MALARIA FROM THE GENERAL PRACTITIONER'S STANDPOINT OF VIEW—THE ROYAL SOCIETY—MEDICAL SOCIETY.

London, May 23, 1902.

Yesterday the Lord Mayor opened the new operating department of the London Hospital. This consists of a theater, four operating rooms, three rooms for anæsthetizing, four recovery rooms or small wards, five operating wards, together with sterilizing rooms and storage room for instruments, etc. Besides these, there are nine other rooms devoted to the use of surgeons, nurses, etc. The department occupies about 275 by 60 feet, and is fitted with electric light throughout. No expense has been spared in the equipment, which seems complete, with every modern appliance, and the buildings are carried out in every particular according to the most advanced sanitary science. The department is well worthy of our largest and, on the whole, perhaps, the best hospital in the metropolis. The money has been provided by a generous Jewish donor, who has made two conditions, viz., that his name is not to be divulged, and that the department is to be open to patients without distinction of religion.

Dr. Wm. Miller Ord, Consulting Physician of St. Thomas's Hospital, died on the 14th inst., aged sixty-seven years. You will, probably, remember him chiefly for his fine work in reference to myxœdema, the pathology of which he laid down, and in other ways completed Gull's discovery. His numerous pupils remember him rather as the brilliant but exact clinical teacher, and regard his investigations into myxœdema as paralleled by other clinical researches. His personal friends dilate on the man and the companion as overshadowing in their estimation the teacher and the scholar. He will be missed for many a year to come.

Dr. Patrick Manson has been discoursing at the Medical Society on the diagnosis of malaria from the standpoint of the practitioner in England. We see but little of it here, much less than you do, I suppose, and therefore your readers may like to have the gist of what so experienced a tropical authority said when he tried to see his subject from the general practitioner's point of view. Recent discoveries, he asserted, enable us to be precise and absolutely sure of the diagnosis in ninety-nine cases out of 100. The pathognomonic indications he arranged as (1) clinical, (2) therapeutical; (3) microscopical. The only classical symptom justifying a diagnosis of malaria was periodicity—but that only tertian or quartan. The appearance of a quotidian periodicity, he said, was common enough in malaria, but it was only an appearance. It was doubtful whether true quotidian periodicity ever occurs, if it does, it must be very rare. The parasites are either tertian or quartan in habit, and the recurrence of the symptoms corresponds. Multiple infection may give rise to diurnal return of symptoms, but that is not true quotidian periodicity, whatever it may be clinically. Therapeutic diagnosis resolved itself into the effect of quinine. In England it never failed to arrest an attack. Persistence after four days' dosing (10 gr. t.i.d.) proves the case is not malarial. But the quinine must, of course, be absorbed. Often, to get the effect on account of the state of the stomach, we must resort to enemata or hypodermic injections. Tablets and coated pills are dangerous.

Microscopical diagnosis is the most satisfactory if the observer has experience. The beginner cannot expect to obtain reliable results. It is easy enough when one has been properly taught and then had large experience. But every practitioner should learn to prepare blood films fit for submitting to an expert. This is often not the case, and Dr. Manson had received many useless specimens. The best method was that of Christophers & Stephens. The patient must not have taken quinine recently, for even in small doses it will cause the disappearance of the parasites temporarily, and sometimes for a long time.

We have known for some years that during and after malarial attacks the leucocytes are diminished in proportion to the red corpuscles, the diminution being chiefly in the polymorphonuclears, so that there is a relative increase in the large mononuclears. This does not seem to be affected by the use of quinine, and so has been considered a diagnostic indication. Drs. Christophers and Stephens reported to the Royal Society that an increase of mononuclears "beyond 15 per cent. is proof of an actual or recent malarial infection." Captain Rogers, I. M. S., endorses this. So does Dr. C. W. Daniels, Superintendent of the Tropical School here. He has had great experience, and is fortified in his conclusions by other observers. He puts the value of the test as about equal to that of agglutination in typhoid fever. It is obvious that a test of this kind can only be properly made by those of wide experience in examining the blood.

To return to Dr. Manson's views on malaria. He repudiates a rather common opinion that the infection may last a lifetime. He believes a malignant tertian tends to die out in from one and a half to two years, a benign tertian in two to two and one-half years, and a quartan in about three years. Old Indians talk of jungle fever when they get a feverish cold, which others call influenza or something else. Dr. Manson has seen many reputedly malarial patients from places in England, formerly malarious, but they all turned out to be something else. He believes the plasmodium has died out in England like the wolf and the wild boar.

As a special hint, he added that a positive diagnosis of malaria does not exclude other diseases for malaria, rather predisposes to them. So, too, an explosion of latent malaria is favored by other infections, especially typhoid and tubercle.

Mr. Bryant brought before the Medico-Chirurgical Society, on May 13, a table of forty-six cases of cancer of the breast which had survived operation for periods of from five to thirty-two years. He has always been of the opinion that the three years of freedom from recurrence commonly laid down as an indication of cure is misleading. In the cases now tabulated there was an absence of recurrence in nine from five to ten years, and in eight from ten to twenty years. Thirteen of these patients are now alive and well. In nineteen cases recurrence took place at the seat of operation; in three of these a second operation was performed, two of them continued well four years, and the third ten years. In nine cases recurrence took place in three to seven years, and in three no second operation was done. There were ten cases of recurrence in which the second breast was involved, and four in which there was cancerous disease in other parts of the body.

Taking the tables as a whole, it appeared that in half recurrence took place in five years or less, in the other half in six to thirty-two years, and in two-thirds of these last the interval was ten years. It is thus clear that operation is not so unsatisfactory as is generally supposed.

In recurrent cases unfavorable for operation, Mr. Bryant said *x*-rays should be employed, but admitted they were not free from danger in inexperienced hands, and a three-months' course seemed the shortest period likely to do good.

Sir W. Mitchell Banks said he at one time lost 10 per cent. of cases. But since the rebuilding of the hospital he had had only one death out of between ninety and one hundred cases. Nothing could be more erroneous than the old three-year limit. Out of fifty-eight cases which he had been able to follow up six died from local recurrence, twelve from general without local recurrence. In twelve there was no return for five to eighteen years; fourteen are now well after five to ten years, twelve after ten to twenty years, and two after twenty and twenty-three years. The most important point was early operation. In his opinion the disease returned in the lymphatics of the skin around the scar, and therefore he removed the skin freely at his operations. But he regarded Halsted's operation as quite unnecessary. When the cervical glands were involved the case was beyond the reach of surgery; when they were not, such an operation was unnecessary and dangerous.

Mr. Godlee then read a paper on "Tropical Abscess of the Liver," and described eleven cases. He thought perihepatitis, which is usually peritonitis, was an element of safety in operating, as it localized abscess. So also pleurisy, when present, might be protective. Extreme chronicity characterized tropical abscess, though some cases were very acute, and these might be multiple and very septic, and should be classed separately. Some had been described as multiple which were not so. Most abscesses are single. The best place to open them, when possible, was in the lower axilla. Most of those in the right lobe could be reached from that situation. Those in the left lobe, and some others, too, must be opened in the epigastrium. The dangers and disadvantages of posterior and lateral incisions were dealt with.

Dr. Patrick Manson remarked that his operation was intended for general practitioners far from assistance. He had never seen serious consequences from the escape of pus into the abdominal cavity.

Dr. Crombie said small abscesses were still successfully treated by aspiration, and even large ones are sometimes cured by repeated aspiration. He had not met with any serious result from this treatment in thirty years' experience, perhaps because the pus was aseptic, for some usually escaped into the cavity. Hemorrhage was apt to occur, but was controlled by pressure.

Mr. James Cantlie advocated Manson's operation of aspiration as far the best for inexperienced or unassisted operators. With it hemorrhage was greatly obviated, as incision with the knife was the chief cause. He advised a rubber, rather than a metal, drainage tube. Among the numerous cases in which he had aspirated only two had been fatal.

Dr. Rockwood said he had operated on 100 cases in twenty-five years. In chronic apyretic cases aspiration sufficed. In acute cases with thick pus excision of rib might be called for, lateral incision failing.

The Royal Society's annual conversazione was held on the 14th inst. There was, as usual, a brilliant assemblage of Fellows and their friends. Numerous experiments and specimens served to entertain the company.

At the annual meeting of the Medical Society of London the election of officers for the ensuing year took place. Mr. A. Pearce Gould is the new president.

Progress of Medical Science.

The Boston Medical and Surgical Journal, June 5, 1902.

A Case of Meningeal Hemorrhage and Nephritis Supervening upon a Purpuric Diathesis of Twenty-five Years' Duration.—Robert T. Edes reports the case of a woman of forty years, who died in March, 1902, after suffering from purpura for twenty-five years. An interesting point in the case is the relationship to rheumatism, as shown by pain and swelling existing at the same time as the petechiæ, but not always at the same place, and on one occasion, at least, when there were no petechiæ anywhere. On the other hand there was a dissimilarity to rheumatism in the complete integrity of the heart, and the absence of atheroma. The existence of acute nephritis toward the end was indisputable. At the autopsy, meningeal hemorrhages were found, without cerebral hemorrhage and without sclerosis, a rare occurrence in this form of purpura.

A Case Mistaken for Phthisis Produced by Half of a Small Dental Plate Lodged in the Right Primary Bronchus.—George F. Pope reports the case of a man who coughed up half of a small guttapercha plate measuring seven-eighths of an inch in the longest diameter and eleven-sixteenths of an inch in the opposite. Two years and a half previously, while wearing a small plate for the four upper incisor teeth, he received a violent blow in the mouth. The false teeth were all knocked out of the plate and it was broken in two. In the excitement of the moment he thought he had inhaled one of the teeth, but the doctors he consulted laughed at the idea, and he never mentioned it again. After this he developed pain in the apex of the right lung, and a troublesome cough, losing health and strength He went from one physician to another, and all but one told him he had phthisis. On physical examination the writer found that the chest symptoms were clearing up, and the patient had gained four pounds in weight since the expulsion of the foreign body one week before.

A Case of Thrombosis of the Central Vein of the Retina, Complicating Carcinoma of the Uterus.—Charles J. Aldrich reports the case of a woman of forty-six suffering from uterine cancer, who was attacked with sudden blindness of the left eye. While straining at stool the week before, she noticed a "film" in front of the eyes. This continued throughout the day notwithstanding the fact that she had no headache. The next day she could not see with the left eye "except in spots." The day following the eye was blind to everything but light. There were no ocular palsies, pupils reacted to light and accommodation, and were of equal size. She suffered from no headache, nor anything suggesting intracranial disturbance. Ophthalmoscopic examination revealed a marked hemorrhagic retinitis in the left eye, which was thought to be due to the obstruction of the central vein of the retina. The slow onset of the blindness, the fibrinous condition of the blood, so commonly present in carcinomatous disease, seemed to argue for a thrombosis rather than an embolism. About two months later the patient could see forms moving about the room, but not the pictures hanging on the wall. The hemorrhages are practically absorbed.

The Boston Medical and Surgical Journal, June 12, 1902.

The Struggle against Consumption.—Edward G. Otis says that the public or state sanatorium subserves three most important purposes: (1) It affords the best means of cure; (2) It isolates the consumptive; (3) It sends forth, in its cured patients, teachers of wholesome hygienic living and of the avoidance of danger from the sputum. Leper houses accomplished the extermination of leprosy in Western Europe—sanatoria alone will not exterminate consumption, but they will greatly aid in so doing. We must also labor in the way of general phrophylaxis, educate the public as to the danger of infection, teach it that in the [illegible] It has been suggested that [illegible] Vaccination [illegible] New York [illegible] per cent [illegible] (1) That [illegible] (2) That [illegible] (3) That [illegible]

New York Medical Journal, June 7, 1902.

Some Considerations on the Hygienic and Prophylactic Treatment of Myopia.—The measures advised by A. Duane are comprised in the following rules: (1) Making the patient wear the full correction of his myopia all the time, and both for distance and near. This is of prime importance in all varieties of myopia, low, medium and high, and, if applied early, may check the progress of the disease altogether. (2) Proper attention to illumination, the size and legibility of the print, the quality of paper and ink, the desk and the relative height and disposition of the seat and desk, and the many other factors that have been brought out by the zealous investigators into the subject of school hygiene. These are important but subsidiary matters. (3) In low and medium myopia moderate restriction of near work, or rather its better distribution, so that it is done mostly by daylight and not for too long at any one time. Furthermore, momentary rest of the eyes at frequent intervals during the work. These rules to be the more strictly enforced the higher the myopia and the younger the patient. (4) In high myopia with evidences of progress, much more stringent restriction of near work. Open-air work to be encouraged and the adoption of confining and eye-taxing occupations forbidden. (5) In medium and especially in high myopia plenty of sleep and out-of-door exercise; (6) Re-examination of the patient at frequent intervals (which in the case of high myopia should be very frequent), to determine how much the myopia has increased. If it has increased, the glasses should be increased also up to the full strength, and the hygienic regulations above detailed modified accordingly.

Gunshot Wounds of the Stomach with Report of a Case.—P. F. Eve reports an interesting case of this nature in which recovery took place. He lays down his method of operating as follows: After assuring himself that the wound has actually penetrated the abdominal cavity, he performs immediate laparotomy and makes careful search for visceral lesions; if any are found, the serous and muscular coats are brought into apposition by inverting the apertures and closed by Lembert's sutures. In a few cases where the openings were quite small, he has used a purse-string suture, strengthened by one or two Lembert's sutures. He makes it a rule, after repairing the wounds of the stomach, to flush out the abdominal cavity with a continuous saline solution, using as much as three to eight gallons in each individual case. This is done because he does not believe we can with certainty determine whether or not any portion of the contents of the stomach has passed into the abdominal cavity. In the after-treatment of these cases great care must be exercised in feeding the patient. He does not allow anything, even of a liquid nature, to pass into the stomach until after the fourth or fifth day, maintaining the patient during this time solely by rectal nutritious enemata. After the fifth or sixth day the patient is allowed at intervals of from two to four hours a small quantity of egg-albumen, augmented by beef-juice, administered about the end of the eighth day. He does not allow the patient to take solid food into the stomach under eighteen or twenty days from the receipt of the injury, and is very guarded even after this period to withhold from him any article of food which would produce fermentation.

Medical News, June 14, 1902.

Stone in the Female Bladder.—H. H. Stoner states that the reason of the infrequency of stone in the female bladder is to be found in the shortness and large caliber of the female urethra. The etiological factors are the same in both sexes. In nearly all the recorded cases of calculi in the female bladder the cause has been assignable to foreign substances introduced from without. These constitute the nucleus. The symptoms of stone are practically the same in both sexes. The stone when once formed must be removed. There are three methods: litholapaxy, suprapubic cystotomy, and vesicovaginal incision. The choice of operation will depend upon the circumstances connected with the case.

Hysteria, Its Etiology and Management.—Joseph M. Aiken declares that hysteria is more frequent in females than in males, and most likely to appear between the ages of ten and twenty-five years. Heredity is an important etiological factor. In hysteria there are sensory, motor and mental symptoms. Certain senses are often perverted. [illegible] is complained of. Sometimes there is a rigidity of the muscles. The mental symptoms are impaired memory and will power. Motor accidents, like paralyses and contractures, occur. Sensory accidents are sudden [illegible] and often [illegible]. They come [illegible]. [illegible] symptoms are many and varied. A continued, remittent or intermittent fever is occasionally found in hysteria. The cause of hysteria is [illegible]. Treatment must be directed mainly to a control of the mental status of the patient. The nervous system must be repaired. Treatment must be general for the disease and special as applied to each individual according to the characteristics of the patient.

Philadelphia Medical Journal, June 7, 1902.

Operations upon the "Green Groin."—Joseph Price states that the class of cases coming under this title would better be called those of gangrenous appendix than appendicitis. Although surgical interference may be prompt in these cases the appendix is found to be gangrenous and sloughing with one or more perforations and a free leakage. A large part of the right groin is filled with brown-colored or septic fluid, the omentum fixed with a cluster of bowel adhesions underneath, occasionally a "dirty, hot" abdomen with the entire peritoneal cavity filled with bowel contents, lymph and other inflammatory products. The fact that large numbers even of the neglected and greatly complicated cases are saved shows how easy it would be to save them all before such unfavorable complications occur. The diagnosis of appendicitis is usually easy. In some cases, however, it is difficult. Some cases simulate typhoid, and must be carefully distinguished. Opium treatment has no place in the management of intraperitoneal pathology, and even as an adjunct to surgery is needless and positively harmful. It favors restlessness and apprehension and blunts centers that should not be blunted. A very good rule to follow is to adopt one of two methods in the fulminating cases. If there is bowel obstruction and persistent vomiting with evidences of a general peritonitis, operate through the central incision, free all adhesions, remove the appendix and drain. If cathartics act freely before operation, and general symptoms are not prominent, then the lateral incision is the one of choice.

A Case of Severed Spinal Cord in Which Myelorrhaphy Was Followed by Partial Return of Function.—Francis T. Stewart and Richard H. Harte report this case. The patient was a woman twenty-six years of age. She had been shot twice with a 32-caliber revolver. One ball entered about one inch to the right of the seventh dorsal spine and passed directly into the spinal canal, the other lodged beneath the skin in the right lumbar region and was easily removed. At the time of the accident the pain of the bullet was felt, then a mighty contraction of the lower extremities, and finally a sensation as if the lower part of the body had been lost. Consciousness was retained. There was immediate and complete abolition of motion and sensation below a line transecting the lower part of the tenth dorsal spine and a point three and one-quarter inches above the umbilicus, the distance between the ensiform and the umbilicus being five inches. This line of demarcation was sharply defined and was superimposed by a belt of hyperæsthesia reaching as high as the ensiform process; just before operation this layer of hyperæsthesia also became anæsthetic. The superficial and deep reflexes of the lower limbs could not be elicited. Three hours after the accident the operation was performed. When the muscles on either side had been dissected back, the right lamina of the seventh dorsal vertebra was found to be crushed in and the left lamina of the same vertebra fractured at its base. The spines and laminæ of the seventh and eighth dorsal vertebræ were removed and the spinal cord was seen to be divided by a space of three-quarters of an inch. The ends of the cord were approximated with three chromicized catgut sutures, one suture was passed anteroposteriorly through the entire thickness of the cord, and the other two transversely. The dura mater could not be approximated. A small gauze drain was inserted down to the cord and left twenty-four hours. The muscles were united and the skin closed. The condition of the patient at the sixteenth month after the accident is most encouraging. The patient voluntarily flexes the toes, flexes and extends the legs and the thighs, and rotates the thighs. Flexion is more powerful than extension. The bowels move every second day and are under perfect control, except when diarrhœa is present. The patient has the sense of touch, temperature, pain and position all over. There are no reactions of degeneration and no trophic changes in the skin or nails. The writers have submitted this case, which they believe to be the first myelorrhaphy performed in man, as evidence of the power of the spinal axones to regenerate.

Philadelphia Medical Journal, June 14, 1902.

Food Preservatives.—Henry Leffmann speaks of a number of food preservatives, as vinegar, salt, saltpeter, which some authorities designate as permissible antiseptics while they call boric acid, salicylic acid and certain other substances poisons. The writer declares that this is an arbitrary statement, as the whole question is one of dose. The question as to what is a poison cannot be answered unless the questions of dose and manner of administration are taken into account. If the word is interpreted broadly, many articles of food would come into the category of poisons. As to the preservation of butter with boric acid, an average consumption of half a pound of butter per week for an adult would mean the ingestion of 17 1-2 grains of the preservative. This is well within the ordinary medicinal dose. As to meat this preserved, there is no evidence to show that the quantity of preservative employed is sufficient to do harm.

A Study of Heredity.—Hiram A. Wright asserts that heredity is a powerful factor in determining the qualities of the physical body, and environment is of minor importance; while, as to the mental and moral traits manifested, environment is the powerful factor, and heredity is entirely inoperative. The writer then refers to precocious children, the so-called prodigies, and states that an ultra believer in heredity will advance the argument of accumulative atavistic influence, or some similar theory. This would imply the transmission from parent to offspring, per spermatozoon or ovum, of actual definite knowledge of music or numbers, or whatever the child excels in, which he holds to be a positive absurdity. The writer believes that prior to the birth of this present body, some have acquired a knowledge of music or numbers and stored it up in the ego (soul), and now there becomes manifest that which was learned in a previous incarnation. Mentally and morally we are the architects of our own destiny, and we are neither blessed nor cursed by heredity.

The Place of Drugs in the Treatment of Stomach Troubles.—Boardman Reed says that the majority of medicines given empirically in cases of so-called dyspepsia probably do more harm than good. Great strain on the nervous system reacts very injuriously upon the digestive infection, and the patient must have rest and time for recuperation. Gastric neurasthenia is far more amenable to treatment by hygienic and mechanical measures, than by drugs. However, a careful use of certain well-selected remedies can often do good, after examinations of the secretions and excretions. Small doses of the bromides, the hypophosphites, the glycerophosphates, dilute phosphoric acid, and the preparations of iron, zinc, arsenic, silver, and gold are among the remedies which can often be so used with advantage, unless they have been used in excess before. In cases of excessive gastric secretion, the administration of alkalies is generally necessary. In acid gastric catarrh, or in round ulcer of the stomach, with hypersecretion, the same treatment is necessary plus lavage in the former and rest in bed in the case of ulcer, besides rectal feeding for a week or two, with milk diet later. In cases of deficient secretion, an entirely opposite line of treatment is necessary. Often from five to thirty drops of official dilute hydrochloric acid with pepsin is very beneficial. Bitter tonics do good in some cases. Massage and exercise have their place. In atrophy, strychnine may be necessary. Intragastric faradism does much good in atonic conditions and in dilatation from atonic causes.

The Lancet, May 31, 1902.

Note on Two Cases of "Ulcerated Sore Throat."—E. C. Bousfield reports two cases of undoubted diphtheria. They were seen in consultation, but the attending physician refused to have a culture made, claiming that the first case was merely one of tonsillitis, though at the time speech was indistinct and palatal paralysis had supervened. The author makes a plea for the abandonment of any such diagnosis as "ulcerated" sore throat. A slough under the conditions suggested means either syphilis or diphtheria. He has had a large municipal experience in handling diphtheria cultures, and advises that the swab be thoroughly wet before it is applied to a suspicious case. Ordinary water will answer for this purpose. The use of a dry swab may cause adherence of the material taken up to its meshes, while a wet swab is compact, and will more surely transfer the poison to the culture medium.

The Powers of Natural Resistance or the Personal Factor in Disease of Microbic Origin.—Stephen Mackenzie considers this question with reference to influenza, tuberculosis, rheumatic fever, and appendicitis. His general line of argument is that there are two factors—the soil and the seed, each necessary to constitute the disease, but that the relative share which they appear to take varies in importance in different diseases. We, as practical physicians, have to obtain our knowledge as to the microorganisms concerned in these diseases and their chemicophysiological action from those who devote themselves to these studies, whilst we have to observe the effects of the microorganisms on the human body, and how the body reacts to the germs of the disease. The infective diseases existed long before the discovery of the germs, and we have accumulated a large store of knowledge of the clinical course, the treatment, and the issue of these diseases. This accumulated experience is of great value, though apt to be overlooked by the keen interest excited by fresh discoveries. It is against this tendency that the author enters a protest, and he points out that what is true is not necessarily new. We must never forget that the *soil* is of as great importance to study as is the *seed* in the proper understanding and treatment of diseases of microbic origin.

British Medical Journal, May 31, 1902.

Quinine in Blackwater Fever.—H. M. Dowler, in a residence of three years in the Dooars, Bengal, cared for nine cases of blackwater fever. Eight occurred in Europeans. With the exception of one fatal case they were all treated with quinine bihydrochloride hypodermically, in doses of from two to three grains. In no case did the color of the urine become darker after its use. After giving some 500 hypodermic injections of quinine, usually the bihydrochloride, in three grains doses for adults and proportionately less for children, in various malarial conditions, the writer has never met with a case of hæmoglobinuria consecutive to its use.

The Curative Effect of the X-Rays on Callous Sinuses of the Abdominal Wall.—D. Berry Hart reports two cases of callous abdominal sinus which healed with marvellous rapidity after a few exposures to the *x*-rays. The first patient had a persistent sinus in the abdominal wall, after an incision in the right iliac fossa to evacuate bloody fluid of unknown origin. This sinus was five to six inches long, and ran from near the iliac spine downward and inward to the uterus. It had existed for several months. In order to see its course, an *x*-ray photograph was taken. This was followed by an almost magical cicatrization of the sinus after plugging with iodoform gauze for several weeks had failed. The second case was that of a sinus, which had persisted for some months in a case of operations for extraperitoneal gestation where fetal bones had been retained for five years. A narrow sinus into the shrunk sac remained. It would finally admit the index finger. Cure was effected after three exposures to the *x*-rays. The sinus has reopened a little, but there may be some bone present.

Remarks on the Removal of Prostatic Adenomata.—William Thomson says that there are many conflicting views concerning the removal of the prostate. Certain surgeons believe it possible to remove the whole prostate, while others believe that this is impossible. A normal prostate would be more difficult to remove than an enlarged one, even in a dead body. The conflict of testimony is perplexing. The opposition is based mainly upon the relation of the normal parts, but it is necessary to take into consideration also the influence of pathological changes which may make possible to the surgeon what is impossible in the view of the anatomist. Some of the opponents hold that there are certain conditions which must attend extirpation of the entire prostate, namely, the concurrent removal of the seminal ducts and the prostatic urethra. If this is true, then it may be truly claimed that the prostate can be completely enucleated, because in several reported cases the urethra and ducts have been so removed. To the patient, at least, it is not of much moment whether a prostatectomy is done, or adenomata only are removed. If the functional ease of former days be restored to him, he will be satisfied. In the writer's own case, he removed two adenomatous tumors, leaving behind a layer of prostatic tissue representing the gland proper, but squeezed out of recognition by the pressure of the pathological growth. Nothing can now be felt in the rectum to indicate a prostate at all, while the bladder function is as good as it was twenty years ago.

Deutsche medicinische Wochenschrift, May 15, 1902.

Diagnostic Value of the Old Tuberculin.—Bandelier, as the result of experimental research and clinical observations, thinks that in the present knowledge the best results in the early diagnosis of tuberculosis are to be obtained by the use of tuberculin and hence that it should come into routine employment not only in tubercular sanatoria, but also in general hospitals and in private practice. In order to obtain reliable results the method of tuberculin injections recommended by Koch must be rigidly adhered to. Tuberculin injections are also the best means with which to determine the existence of recovery in any given case.

The Operative Treatment of Large Umbilical Hernias and Ruptures of the Abdominal Wall.—Heinrich says that in radical operations upon large umbilical hernias the best results are to be obtained by overlapping the fascia of the opposite recti muscles, but leaving the muscles themselves entirely intact. The essential point consists in freeing a sufficient portion of the fascia of one rectus and uniting it by silk sutures to the fascia of the opposite rectus. Catgut is not suitable for such suturing and such would be absorbed before firm union had taken place. The silk suture is left permanently in situ. If proper antiseptic precautions are followed no suppuration occurs. By following this method the recti are left intact and the abdominal wall is not weakened. The latter always occurs in large umbilical hernias when the recti muscles are directly united, their fibers being transversely separated by the tension produced. When the rupture does not occur in the median line the fascia of the recti cannot, of course, be used and a direct union of the abdominal muscles is necessary.

Deutsche medizinische Wochenschrift, May 22, 1902.

Pneumococcus Sepsis.—A. Prochaska reports, in detail, four cases in which the pneumococcus was isolated in pure culture from the blood. These micro-organisms were also present in the sputum in all the cases. In one case in which a nephritis was present they were found in the urine. The symptomatology and course of the infection were somewhat varying. In all the cases the primary symptoms were pulmonary and were merely those of an ordinary bronchial catarrh. In the first case a hemorrhagic nephritis soon developed, ran an acute course, and terminated in recovery. Cases two and three were characterized by a marked periodicity in the symptoms. For this reason careful search was made for the malarial organism, but without avail. The subsequent isolation of the pneumococcus from the blood in both cases definitely settled the etiology. In both cases recovery took place. In the fourth case the primary bronchitis was improving when suddenly high fever, cyanosis, and collapse appeared. Death shortly supervened. In none of the cases was there any pulmonary consolidation. The author believes that pneumococcus sepsis is much more frequent than is generally supposed, and that in many cases the clinical picture known as "grippe" or "influenza" is attributable thereto. A bacteriological examination of the blood is greatly to be desired in all similar acute infections in which the etiology cannot be definitely determined in some other manner.

Berliner klinische Wochenschrift, May 19, 1902.

The Results of Nitrate of Silver in Ophthalmia of the New-Born.—Ernst Runge disagrees with Ludwig Hirsch, who holds that nitrate of silver does not give uniformly good results in preventing ophthalmia in the new-born. Runge reports 1,000 cases which were so treated. In none of these did the disease develop immediately after birth. In one case ophthalmia appeared during the second week of life. These cases taken in conjunction with those reported by Schallehn in 1897 make 1,917 cases which were treated with nitrate of silver. In none of these was an early infection present, and in only three a late infection (during the second week). Runge used a 2-per-cent. solution of the nitrate, but Gusseron has shown that a 1-per-cent. solution is equally efficient. In all cases the instillation should be practised not later than one hour after birth. If practised after this time the results obtained are not nearly so good. In cases subsequently to be reported it is greatly to be desired that the time of instillation be noted.

Tubercle Bacilli in the Nail Dirt of Children.—Kornel Preisich and Aladar Schutz report the examination of the nail dirt of sixty-six children with a view to demonstrating the presence of tubercle bacilli therein. This was successfully done in fourteen cases or 21.2 per cent. The children were taken promiscuously without respect to their living in tuberculous surroundings. Of the fourteen cases in which tubercle bacilli were found nine gave an hereditary history of tuberculosis. In all cases in which an hereditary history of bone tuberculosis was present tubercle bacilli were found. The method used in demonstrating the presence of the tubercle bacilli was usually that of the stained preparations. At first animal inoculation was tried but it was found that very frequently the animal quickly died of some acute infection. This work demonstrates the importance of the nail dirt of children in the spread of tuberculosis.

Berliner klinische Wochenschrift, May 26, 1902.

Mechanism of the Action of Amboceptors.—P. Ehrlich and H. Sachs bring forward two facts to show that the amboceptors do not "sensibilize" the red blood cells, as claimed by Bordet, but that they unite with the complements to form a third substance (hæmolysin), which produces the phenomena of hæmolysis. In the first place, complementoids, which may be present in inactive sera, unite with amboceptors of active sera which have been heated to 50° to 51° C. for thirty minutes, and prevent the reactions of such sera when a complement is subsequently added. Furthermore, if normal hæmolytic ox serum is heated for thirty minutes to 55° C., and then the red blood cells of the guinea-pig are placed in contact with it for one hour at 37° C., and then centrifuged off, the addition to them of a complement does not produce hæmolysis, showing that such red blood cells have not been "sensibilized." If, however, the red blood cells are kept at 0° C. for one hour with the inactive ox serum and at the expiration of this time a complement is added to the entire mixture, hæmolysis promptly occurs, showing that the amboceptors have not been taken up by the erythrocytes but are still present in the fluid.

"Tube-Shaped" Vision Field in Hysteria.—Richard Greeff describes, under this name, a marked concentric contraction of the field of vision which is characteristic of hysteria and which is available for diagnostic purposes. Many cases have been observed by the author which bear out this statement. In these cases the acuteness of vision is practically normal, but ophthalmoscopic examination shows a marked contraction of the field of vision. Pain in the eyes is often a prominent symptom. Various nervous manifestations are usually present. The entire clinical picture may closely simulate an organic ocular or nervous condition. A case in exemplification is reported in detail.

Munchener medicinische Wochenschrift, May 20, 1902.

Hæmoglobinuria of Pregnancy.—L. Brauer describes under this name a form of hæmoglobinuria which occurs during pregnancy, which is accompanied by icterus, but which is not assignable to any definite cause. A case is reported of a woman who had gone through six pregnancies, in the last three of which hæmoglobinuria and icterus had been present, but had quickly subsided after labor. The patient many years previous had experienced an indefinite attack of malaria, but the hæmoglobinuria could not reasonably be attributed to this cause. It is probable that in these cases the hæmoglobinuria is brought about by the action of metabolic products formed during pregnancy upon red-blood cells of diminished resistance.

Antithyreoidin Treatment of Graves's Disease.—Schultes reports the treatment of a case of Graves's disease with the antithyreoidin preparation as recommended by Möbius. The patient had suffered from the disease for about four years, which during this time had increased greatly in severity, although various forms of treatment had been used. Of the diagnosis there could be no doubt. Both Stellwag's and Gräfe's signs were present. When the administration of anti-thyreoidin was begun all other treatment was suspended. This was begun in doses of 0.5 three times daily and gradually increased until the daily dose amounted to 13.5. At first the drug was given in sherry, but later raspberry juice was substituted. The entire period of administration was about two months. At the end of this time the patient was greatly improved. The pulse rate, which at the beginning was 120 per minute, became normal. The thyroid gland was reduced markedly in size. All the nervous symptoms had completely disappeared. The exophthalmus, however, was not altered, and was fully as prominent as at the beginning of the treatment.

The Serum Treatment of Graves's Disease.—Wilhelm Goebel reports the successful treatment of a case of Graves's disease by the administration of the milk of a goat whose thyroid gland had been extirpated. Since, however, other treatment (massage and electricity) was conjointly used the recovery cannot reasonably be entirely attributed to the milk. With the disappearance of the subjective symptoms both the exophthalmus and thyroid enlargement were much reduced. For many reasons it is not reasonable to suppose that the milk or serum of animals, from whom the thyroid gland has been removed contains an anti-body, that is a substance which neutralizes thyreoidin, since the effects produced by these are very different from those obtained by the administrations of known anti-sera (anti-tetanic and anti-diphtheritic). It is generally supposed that the symptoms of Graves's disease are caused by an overproduction by the thyroid gland of thyroid-iodine. This substance, however, can only be produced when iodine combinations are present in the body. Since the thyroid gland is the only organ of the body which can produce such combinations the milk and serum of animals from which this gland has been removed cannot contain such iodine combinations. Consequently when such milk or serum is administered as food to patients with Graves's disease, thyreoidin is not formed at all or only in very small amount. It seems certain that the beneficial effect of these substances is thus to be accounted for.

Münchener medicinische Wochenschrift, May 27, 1902.

Treatment of Melæna Neonatorum.—Max Döllner draws attention to the value of subcutaneous injections of gelatin in the treatment of this condition. A case is reported of a child two days old in which violent and persistent intestinal hemorrhage was present. At hourly intervals three subcutaneous injections of 10 c.c. each of a 2 per cent. gelatin solution were administered. Marked improvement took place after the third injection, but since there was slight hemorrhage five hours thereafter an additional 10 c.c. of the gelatin solution was given at that time. Rapid recovery occurred. Since the therapy of melæna neonatorum has hitherto been practically without avail, the extended use of subcutaneous gelatin injections is earnestly advocated.

New Method of Tendon Transplantation.—Max Mainzer says that, in many instances in which it is impossible to unite the tendon of the paralyzed muscle directly with that of the sound muscle because of the excessive tension thereby produced, the latter muscle may be prolongated with a portion of the tendon of another paralyzed muscle. Hitherto such prolongation has been accomplished by means of catgut or silk ligatures. In certain cases the mechanical irritation produced by the catgut or silk gives rise to results which are ultimately unsatisfactory. In this class of cases the method here advised is of special utility. Two cases are reported in which it was adopted. In the first case the tendon used for prolongation was completely separated from its own muscle, but in the second case this continuity was not disturbed. Equally good results were obtained in both cases and the method is earnestly recommended in all cases in which silk or catgut ligatures are contraindicated.

Diagnosis of Actinomycosis.—Karl Doepke says that, bacteriologically, a diagnosis of actinomycosis can be made in three ways: (1) By the microscopical examination of an unstained preparation of the purulent material and the demonstration of characteristic bulbous rods therein; (2) By the microscopical examination of a preparation stained by Gram's method, in which there may be seen long rods or threads devoid of bulbous extremities. The spore-forms are usually encountered free in such a preparation; (3) By the microscopical examination of sections stained by Gram's method, in which both bulbous and non-bulbous rods or threads are found. It should be remembered, however, that while the demonstration of the bulbous forms establishes a diagnosis, their absence does not negative a diagnosis. The bulbous portions of the rods or threads are true spores which, under favorable conditions, may develop (1) into chain-like bulbous threads; (2) into long spiral rods, and (3) into short or long segmented threads. A sufficient observation of the vegetative forms always shows the formation in them of spores.

French and Italian Journals.

Acute Œdema of the Cervix of the Gravid Uterus in a Multipara Who Five Years before Had Had a Unilateral Ablation of the Adnexa.—Delestre reports Varnier's observations on a patient who suffered from œdema of the cervix uteri. By means of photographs taken of the patient under observation he has convinced himself that the gravid uterus did not sink down during the crises of cervical prolapse. The labor in this case was normal. Varnier states that since the preceding pregnancy, six years before, the patient had had no sign or symptom of prolapse. Extirpation of the adnexa on the left side for ovarian cyst, four years before, had deprived the uterus of one of its ways for discharging its secretion.—*Le Bulletin Médical*, May 24, 1902.

Treatment of Smallpox by Red Light and Antisepsis.—Barbary has done some good work in this line. He placed eight young patients in rooms which were lighted only by red light. Even the lamps that were used of red glass. Besides this a vigorous antiseptic treatment was instituted. Four times a day lotions of sublimate, 1 to 2,000, were used on the bodies of the patients, and twice a day lotions of the sublimate, of the strength of 1 to 4,000, were applied to the faces. Also, twice a day the following powder was applied to the face: Salicylate of sodium 5; cherry laurel water, 10; alcohol, 10; The patients took every day 1 gm of phenic acid. Under this treatment the patients have had almost no fever, the convalescence was rapid and no scars were left.—*La Médecine Moderne*, May 21, 1902.

Some Modifications of Schenk's Method (Artificial Hyperæmia) in the Treatment of Pulmonary Tuberculosis.—Torindo Silvestri first describes Schenk's method of inducing hyperæmia by stasis in consumptives in order to favor the formation of connective tissue, attenuation or destruction of the microbes, and to exercise an absorptive action on certain pathological formations of an inflammatory nature. To obtain this hyperæmia the patient must be kept in a position of lateral decubitus on the affected side, and the bed should be so inclined that the pulmonary apex is lower than the trunk. The writer does not approve of the hot local applications advised by Schenk, but prefers cold sponging. He reports the history of the treatment of two cases, in which the result was all that could be desired.—*La Riforma Medica*, May 17, 1902.

Some Indications for the Physiological Serum.—Luigi Fornaca and Ferdinando Micheli have found that injections of physiological salt solution, in doses varying from 10 to 50 c.c., are of great benefit in convalescents whose nervous system needs stimulation, in hysterical, neurasthenic, and paralytic patients in the stage of depression—the action on general nutrition is marked, and the functioning power of all the organs is improved. The action of the serum appears to consist in an increase in the resistance and in the number of the red-blood cells, in modifications of the nutritional exchanges as shown by increase of the urine and of urea, stimulation of the functions of bone marrow and of the liver cells, increased activity of the heart and kidneys, with restoration of the circulatory equilibrium, and a consequent increase of reflex excitability of the nerve centers. The action of the serum is therefore seen to be both stimulating and antitoxic.—*La Riforma Medica, May* 9, 1902.

The Histological Changes Caused by Colloid Metallic Solutions and by Electrolytically Dissociated Solutions.—G. Galeotti and C. Todde conclude that colloid metallic solutions, especially of metals such as platinum, gold, and silver, which are soluble with difficulty, affect the organic nutritive exchanges, and even the cellular metabolism of certain tissues. The result is grave loss of strength and considerable cellular atrophy. The circulatory changes, such as infarct, stasis, and hemorrhages, which occur, may be considered as secondary and dependent on the impaired condition of nutrition of the tissues and especially of the blood-vessel walls. On the other hand, after treatment by the same metals, given in the form of saline solutions, we have the symptoms of a somewhat slow intoxication, with degenerative phenomena in the various organs, to be explained by the supposition of direct combinations between the metallic irons and the protoplasmic molecule, which altogether change the structure of the latter.—*Lo Sperimentale*, Vol. 56, No. 11.

Action of Grape Juice on the Organism.—The grape is composed of various constituents which give it its value in the so-called grape cure. Water, grape sugar, cream of tartar, tartaric and malic acids, albuminoids, various minerals, as potassium salts, lime, magnesia, the oxides of iron and manganese, a little silicium and alumina, also certain acids-phosphoric, sulphuric and nitric. There are traces of chlorides and a small quantity of soda, and phosphates, The seeds contain tannin. Grape juice from its constituents is a veritable natural mineral water. In taking the grape juice cure the quantity at first taken is small and is gradually increased, the length of the time of treatment being from three to six weeks. Walking and exercise in the open air assist very much in bringing about good results during the time of this cure. The general health is improved, the appetite is increased, and the digestive functions are greatly improved. The patient usually puts on flesh. This cure is especially indicated in affections of the digestive organs, visceral congestions, ascites, jaundice, in cases of hepatic calculi, diarrhœa, habitual constipation, in certain skin troubles, and in neurasthenia; pulmonary tuberculosis is benefited by this treatment, but the intestines must be in good condition. It seems contraindicated only in persons who are too fat or who have a tendency to become so, and during the period of menstruation.—*Gazette Hebdomadaire de Médecine et de Chirurgie*, May 22, 1902.

Prophylaxis and Treatment of Eczema in Sucklings.—A. Schwab states that we should bend our efforts toward the proper nourishment of infants, and thu avoid digestive troubles, which are the consequence of improper [illegible] Warm and milk are good drinks for the nursing mother. [illegible] Instead of giving drugs the child's intestines should be carefully watched and great care must be taken to avoid the formation of [illegible]. Moderate use of alkalies, a bit of bicarbonate of soda, used for a laxative, magnesia can be recommended. As for local applications, the simpler they are the better. Inert powders are the best. These combined with an emollient to loosen the crusts, after the treatment of [illegible]. It is also important to see that the child does not scratch itself. It may be necessary to tie the hands during the night.—*La Presse Médicale*, May 21, 1902.

Cancer of the Ampulla of Vater.—Maury reports the case of a man aged sixty-seven years with cancer of the ampulla of Vater. The symptoms were those which have been established by Hanot and Rendu: insidious onset, intermittent jaundice and frequent diarrhœa. Later, when the orifice of the ductus choledochus was completely obstructed by the tumor, the jaundice became permanent.—*Journal des Praticiens*, May 24, 1902.

Chronic Rheumatism of the Large Joints.—This case is reported by Variot. The patient was a boy of twelve years. After an attack of scarlet fever he was affected with rheumatism, which was localized in the large joints, the shoulders, elbows, hips, and knees. The fingers were not affected. This attack was followed by ankylosis of the joints affected and trophic troubles of the skin, which was hard, infiltrated, œdematous, and covered with scales. These cases are rare. The child was treated with great success for five months with hot baths, the iodides, and massage. He seems to walk better after taking lemon juice according to the method of Desplats.—*La Presse Médicale*, May 24, 1902.

Fibroma of the Uterus; Ulcerated Polyp of the Uterus.—The subject of this case, a woman thirty years of age, was a patient of Duret's. She was a widow. Since the age of fourteen years she had suffered from extreme paroxysms of pain in the lower abdomen. These attacks would be followed by periods of comfort. Metrorrhagia had supervened for some years. The cause of this was explained after the operation by the discovery of an ulcerated, senile polypus in the body of the uterus. The fibroma was of the size of two fists and was taken out piecemeal on account of its position and peritoneal adhesions which made it very difficult to remove. The ovaries were sclerocystic.—*Journal des Sciences Médicales de Lille*, May 24, 1902.

Changes in the Pulse in Childhood.—G. A. Dotti asserts that the pulse undergoes greater changes normally and pathologically in children than in adults. In typhoid fever arrhythmia appears from the fifteenth to the thirtieth day and disappears from the thirty-fifth to the fiftieth. In pneumonia the pulse resembles that of typhoid fever more than it does in other pulmonary diseases, in which there is irregularity rather than a true intermittence. In influenza the arrhythmia appears somewhat early. In diphtheritic angina of slight import there is merely tachycardia and a small pulse, but in grave cases there is bradycardia. This also occurs in the convalescence from scarlatina.—*Rivista Critica di Clinica Medica*, May, 1902.

Retention of Chlorides in Nephritis.—Ch. Achard and M. Loeper have given this subject considerable attention. This retention of chlorides is met with under two conditions: (1) In nephritis which complicates an acute disease and in acute primary nephritis; (2) In the acute attacks which are incident to the course of chronic nephritis. In acute nephritis the chlorides ingested are eliminated in a variable proportion, but generally feebly. In chronic nephritis aside from attacks of uræmia, sometimes a large proportion of the chlorides ingested passes into the urine. When uræmia exists, the elimination is small; when the uræmia is fatal the elimination is nil. The authors conclude that the deficiency of chlorides in the urine is not a direct effect of the renal lesions, the modifications of the excretion of chlorides are not exclusively dependent upon the state of the kidneys.—[illegible], May 24, 1902.

Scleroderma.—[illegible] which [illegible] becoming rigid and [illegible]. It [illegible] having the appearance of old ivory, with violet colored patches here and there. It is not quite known whether [illegible] the [illegible] body. Its nature is a cause of dispute to both neurologists and dermatologists. The disease has certain relations to myxœdema. It is seen [illegible], later and menstrual troubles are the cause. When scleroderma is localized it can be cured; when it is generalized it is cured with difficulty. The remedies employed are general and local. The first [illegible] is the open air, inhalations of oxygen, hydrotherapy, cod liver oil, antiphlogistics, salicylic acid both internally and externally. The writer has had no results from thyroid extract. The local treatment consists of electrolysis, the continuous electric current, electric baths and massage. Sometimes arsenic, strychnine, the phosphates, bromides and valerianates are given.—*Gazette des Hôpitaux Civils et Militaires*, May 20 and 22, 1902.

Books Received.

A Practical Treatise on Smallpox. By George H. Fox. Parts I and II. Illustrated. J. B. Lippincott Company, Philadelphia, Pa. Price, $3.00.

The Neuroses of the Genito-Urinary System in the Male with Sterility and Impotence. By Dr. R. Ultzmann. Second edition, revised. 12mo, 198 pages. F. A. Davis Company, Philadelphia, Pa. Price, extra cloth, $1.00 net.

Minor Surgery and Bandaging, Including Treatment of Fractures, Etc. By Henry R. Wharton, M.D. Fifth edition. 12mo, 621 pages. Illustrated. Lea Brothers & Co., Philadelphia.

Intubation du Larynx (Instruments, Technique, Avantages). By Le Dr Perez-Avendano. 18mo, 274 pages. Illustrated. C. Naud, Paris. Price, Fr. 4.

Society Reports.

AMERICAN MEDICAL ASSOCIATION.

GENERAL SESSION.

Fourth Day—Friday, June 13.

This, the closing session, was held at noon, and was very brief, occupying not over ten minutes. The attendance was in keeping with the brevity of the session, there being only about sixty present. An epitome of the work done by the House of Delegates was presented.

Electioneering Debars from Office.—The following resolution, presented to the House of Delegates by Drs. Forshay and McCormack, was adopted amid applause:

Resolved, That it is the sense of the House of Delegates of the American Medical Association that the solicitation of votes for office is not in keeping with the dignity of the medical profession, nor in harmony with the spirit of the association, and that such solicitation shall be taken to be a disqualification for any office in the gift of the association.

Distribution of Samples.—At the request of the section on Materia Medica the rule was adopted, that the distribution at the meeting of samples and of advertising matter shall be limited to persons bearing the official badge of the association.

Committee on Reciprocity.—The question of securing uniform requirements in the different states for a license to practise medicine was one that came up on several occasions and would not down. Finally, on motion of Dr. William H. Welch of Baltimore, the President appointed the following committee to consider this important subject and report at the next meeting of the House of Delegates: Drs. W. L. Rodman, Pennsylvania; William H. Welch, Maryland; Joseph M. Matthews, Kentucky; H. Beates, Jr., Pennsylania, and Murray, Montana.

Committee on Revision of Code of Ethics.—The following were appointed on this committee: Dr. E. Eliot Harris of New York, chairman; Dr. Joseph D. Bryant, New York; Dr. T. J. Happel, Tennessee; Dr. Nicholas Senn, Illinois; and Dr. William H. Welch, Maryland.

Representation of the Sections.—It was proposed to amend the by-laws so that "Each Section shall have the privilege of sending to the House of Delegates one delegate for every 500 members registered in such section at the annual session at which the delegates are elected, and one for each fraction of that number; but each section shall have one delegate." It was also proposed to repeal the section of the by-laws providing for alternate delegates.

Place of Meeting.—The question of the place of meeting was reconsidered, and instead of Hot Springs, Ark., New Orleans was chosen, the meeting to be held there between May 1st and 15th, 1903.

SURGICAL SECTION.

Third Day—Thursday, June 12.

The Symptomatology of Renal and Ureteral Disease.—Dr. C. L. Leonard of Philadelphia had found that the larger the calculus in the kidney the fewer and less severe the symptoms. When the calculus entered the ureter while in its progress downward intermittent hydronephrosis often occurred. With complete infraction there were no evidences in the constituents of the urine to show which kidney was at fault. The persistence of pyelitis or a cystitis should excite suspicion of the presence of a stone in the ureter. After a stone of small size had been demonstrated in the ureter, the expectant line of treatment should be followed, as the stone would in all probability be passed spontaneously. Pus could only be of value in the diagnosis when its source had been demonstrated by the catheter in the ureter. Rœntgen rays were the most valuable means of diagnosis of the presence of stone.

Infrapubic Section for Prostatotomy and Prostatectomy.—Dr. E. Wyllys Andrews of Chicago read this paper and said that unless the bony and ligamentous structures outside the gland crowded it there would be no stoppage to the flow of urine even in great hypertrophy. The prostate was situated in a rigid triangle under the symphysis pubis with ligaments behind, so that there was not much mobility given to it. It was advised that the supports to the gland below be cut away and then it would drop back and permit a free flow of urine through the urethra. In speaking of the various routes for operation on the gland the advantages of the suprapubic route was described as easiest of all. The Barnes bag in the rectum pushed the gland up into view, and the Trendelenburg position helped this. Bimanual enucleation was easy, one finger in the rectum to push up the gland and the fingers of the other hand to enucleate through the bladder. The disadvantage was the laying open the urinary tract to the possibility of infection. The ideal operation left the whole urinary tract unopened. The good results obtained from breaking down the supports of the prostate had been evidenced in the author's experience. It was advised that the levator ani be cut to permit the whole of the pelvic contents to fall backward, as this did not cause them to infringe upon the rectum, the coccyx also falling backward.

Drainage of Extravesical and Extraperitoneal Suppuration of the Male Pelvis.—Dr. Eugene Fuller of New York said that the blood vessels in the male pelvis played a most important rôle in controlling the direction of the course of pus spread in the male pelvis. Should the pelvic cavity fill, the pus was liable to run up over the pelvis to the kidney behind, over the symphysis in front or laterally burrow over or above Poupart's ligament down into the groin. Other courses were mentioned. The causes of suppuration were twofold. One through suppuration in abdominal cavity and spread to the pelvis or from outside, such as in symphyseotomy. The second source was infections within the pelvis itself; urinary extravasations, lacerations of the prostate and of the rectum. Clinical symptoms were liable to obscure, but were chiefly due to the primary injury. Frequent urination, without involvement of the bladder, localized pain, contraction of a leg and such symptoms were suspicious. Diagnosis made in special locations by palpation and vesical exploration. If the tumefaction be made out through rectal examination, no opening should be made into the rectum for drainage.

External Urethrotomy from the Standpoint of the General Surgeon.—Dr. J. C. Munro of Boston was sure that every surgeon should be an expert in this operation as it was a common and most fascinating one. It was rare that the urethra had to be opened from above. After the drainage tube, in four or five days he passed a small sound first, and immediately after its withdrawal put in a full-sized sound. This was repeated every third or fourth day. Unfortunately, the end results of these operations were hard to judge, as the patients were a dissolute set, who soon left when slight improvement came, then, later, they would wander from one hospital to another, and so the surgeon lost track of them.

Dr. Arthur T. Cabot of Boston often had to diagnose renal calculi without the presence of classical symptoms. Some moderate hydronephroses ended in malignant disease, and the differentiation was often difficult. Where negative evidence was required the ray was not to be depended upon. He did not think that a single skiagraph should be relied upon for a diagnosis of stone, for sometimes the *x*-ray failed to show them, as in stones below the brim of the pelvis the *x*-ray was interfered with by the bones. The situation of the pain was the most reliable symptom in the localization of the stone.

Dr. Murphy of Chicago showed that a partial prostatectomy might result in a urinary fistula because the prostatic urethra was of large caliber, and when the [illegible] that portion of the prostate [illegible] a pouch with a small fistula being formed at the bottom of the [illegible] to the floor of the perineum. Hence [illegible] a large portion of the [illegible] gland should be removed.

Dr. [illegible] urged the advantages of the cystoscope in the diagnosis of kidney [illegible] and bladder disease. [illegible] had become a fad and [illegible] in all cases. He did not want to [illegible] except that it should [illegible] cases where the patient was [illegible] operation would give excellent results. In fifty cases operated upon by this method there had been [illegible] results had no recurrence. The success of the operation depended upon the possession of an instrument [illegible] to suit each particular case. No hard and fast rule could be laid down for the use of the [illegible] in every case.

Dr. [illegible] Sims of New York favored the perineal route above all others in every case. The Bottini operation was not [illegible]. It was best to dilate the bladder with a rubber bag before enucleating the gland, as in that way hemorrhage was controlled.

Dr. [illegible] Fuller of New York thought that every case should have a prostatectomy done just as soon as possible to get at the patient and operate.

Essentials in the Construction of Hospitals for Great Cities.—Dr. J. A. Ochsner of Chicago repudiated the idea that it was necessary to spread a hospital over a large area of ground. In building a hospital to-day modern conditions must be taken into consideration. It was wrong to put a hospital away from the residence portion of the city, as it was difficult to get the best physicians to attend such institutions. It would be well to have the hospital with a large space of ground about it, and to have it overlook a driveway or park. He advised building the institution several stories high, as the top stories would get practically the same air as in the country. It was not necessary to have a separate building for infected cases, because infection spreads by contact. Small wards were better than large ones. The old idea of fire in high buildings was now out of date in this time of absolutely fireproof construction. Elevators were so perfect to-day that the handling of patients was convenient. The modern hospital should face east and west, so that there would be sufficient sunlight. High buildings were more compact and were less expensive to heat, and took fewer attendants to do the work.

Dr. Sherman of San Francisco thought it was necessary to have hot and cold water in every ward, as it economized the time of the physician and nurse. Certain cases would necessarily have a prolonged convalescence, hence he advised having an annex in the suburbs of the city where these patients could be sent.

Anatomy for the Practitioner.—Dr. C. M. Jackson of Columbia, Mo., urged the necessity of post-graduate work for the practitioner both normal and pathological. It was possible for almost every physician to do this sort of work in his office. Anatomical material was available in every city. The laws of almost every State had provided a means whereby the cadaver was at the disposal of the medical man. These laws were divided into three classes: (1) States in which there were no statutes regarding the distribution of the unclaimed dead; (2) States where dissection was alone limited to the medical schools; (3) States where cadavers were free for every practitioner. These facts had been ascertained by writing to the Secretary of State or the secretary of the State Medical Societies. The best way to study the anatomy normal and pathologic was to embalm the bodies and cut them into sections. This could be very easily done. The methods of preparing and sectioning the bodies were given in detail.

Anatomical Treatment of Fractures of the Femoral Neck.—Dr. E. B. [illegible] of Kansas [illegible] read this paper. With the usual treatment of these cases the results were unsatisfactory. His method was to apply [illegible] to [illegible] in the thigh as in Buck's method, and [illegible] lateral [illegible] by means of a band about the thigh just below the perineum in the [illegible] axis of the neck of the femur. The treatment was the same in all cases except where there was impaction. [illegible] of the fragments [illegible] ligament was employed as an axis. [illegible] and failure to maintain the [illegible] were the causes of failure to get bony union [illegible]. The action of the [illegible] in these fractures was as important as in any other portion of the body. The direction of the lateral extension should be about [illegible] degrees outward and forty degrees forward. Pain always ceased after lateral traction had been made. Of [illegible] cases [illegible] resulted in perfect union, and in [illegible] there [illegible] was [illegible]. Five of the successful cases were over fifty years of age.

Treatment of Fracture of the Patella by Subcutaneous Purse-String Suture.—Dr. John B. Roberts of Philadelphia said he had obtained excellent results by this method in transverse fractures of the patella. He would not operate immediately after the operation, but would put the knee in extension and flex the thigh on the abdomen, and apply cold for three or four days to reduce swelling and keep down hemorrhage. At the end of that period he cleansed the skin and passed a chromicized catgut suture about the bone, bringing the fractures as close together as was possible. In this way the prepatella bursa and the joint were not touched, thereby lessening the possibility of infection. The joint was then encased in a plaster cast and the patient put on crutches and permitted to go about his duties. At the end of the fifth week the cast was cut down and the knot removed. He had always gotten good results by this method.

Dr. Levings of Milwaukee advised waiting a few days after the accident before operating.

Dr. Lord of Omaha said that bony union of the neck of the femur will take place in the aged if immobilization is maintained long enough.

Dr. Carl Beck of New York had seen cases of fracture of the patella in which strong silver wire had not been sufficient to hold the fragments together.

Acquired, Non-Malignant Stricture of the Rectum; Causes, Symptoms, and Treatment.—Dr. W. D. Bullard of New York said that syphilis was not to be considered the most important etiologic factor in the causation of rectal strictures—chronic local irritation from any cause would produce it. Trauma in the female was the most frequent cause. An enlarged uterus or a retroflexion would shove up the rectum into a bulging prominence, and the concomitant obstipation by the passage of the hard fecal masses would induce ulceration of the projecting mucous membrane, ultimately resulting in stricture. Stricture was not caused very often by ulceration of the rectal valves. Prolapse of the rectum may narrow the lumen of the gut, and induce ulceration, which may result in stricture if not properly treated. It was advised that the general practitioner learn to recognize the presence of ulcers of the rectum and learn to employ local treatment.

Dr. W. J. Means of Columbus, Ohio, advocated the oblique incision of the fibers of sphincters in operating on rectal strictures, for the same reason as in cutting tendons.

Surgery of Rickets.—Dr. H. L. Taylor of New York, in an abstract of his paper, said that of all the cases treated in the Ruptured Crippled Hospital in New York 15 per cent. were of rachitic origin, and a large majority of these cases were under five years of age. All cases of bow-legs were not due to rickets. Some were produced by mechanical factors. Improper nutrition was the chief factor in the production of rickets. Rachitic spine must be diagnosed from Pott's disease of the vertebra. Here one did not find the sharp knuckle of Pott's disease, but a rounded kyphos. Pigeon-breast could be cured by removal of obstructions to the respiratory tract, especially enlarged tonsils and adenoids. Lung gymnastics were of great assistance. He then briefly reviewed the results of their various orthopedic operations in rachitic conditions.

Two Successful Operations for Brain Tumor.—Dr. Joseph Ransohoff of Cincinnati, Ohio, narrated the histories of two cases of brain tumor, and showed the specimens. One was a case of gliosarcoma, now living, nine years after operation. He thought that this was the oldest case on record. The second case was operated upon and a tuberculoma was removed from the arm-lip center. In reviewing the diagnosis the more marked the general symptoms, the less emphasized the localizing symptoms. This is the eighteenth recovered case of removal of a tubercle from the brains: four are now living, one five years after the operation. Of the thirty-five brain tumors operated upon only fourteen have recovered.

Fracture of the Lower End of the Radius Illustrated by Lantern Slides.—Dr. Carl Beck of New York gave a most interesting demonstration of the true condition of affairs in fracture of this locality, by means of *x*-ray pictures. He said that fully 85 per cent. of all fractures occurred in this region. Contrary to the fixed idea, the *x*-ray showed that the lower fragment in Colles's fracture might be displaced downward and sidewise toward the ulna. In this condition he employed a rubber catheter in the interosseous space to push the lower fragment out. The *x*-rays showed that plaster of paris was the best method of putting up these fractures. The thumb must be in the proper position to hold the fragments in apposition.

Fourth Day—Friday, June 13.

Traumatic Rupture of the Abdominal Viscera.—Dr. D. N. Eisendrath of Chicago said that the object of the paper was to call the attention of the profession to the general lack of knowledge concerning this class of injuries, and the necessity in future of earlier diagnosis and operation. Traumatic ruptures were more frequent than gunshot and stab wounds together. Ruptures of kidneys and intestines formed 60 per cent. of injuries; next came liver and spleen. Mechanism of injury has much to do with which organ was involved. Hence it was necessary to inquire exactly what was the nature of the force. Force acted either directly or indirectly. In the former, if over a large area, a parenchymatous organ was more likely to be ruptured. If over a circumscribed area, the intestine or bladder would more certainly be ruptured. In direct force, such as falls on the feet or buttocks or head, the liver and kidney might be affected.

A Study of the Relative Merits of the Various Methods of Intestinal Anastomosis.—Dr. R. C. Coffey of Portland, Ore., has practiced these various methods on over 600 cadavers and on twenty pigs. These animals were chosen because their intestine closely resembled that of the human subject. In accuracy, the Connell and Halsted methods. In the Connell continuous suture the ligature had been found in the lumen of the gut two and a half months after the operation. The O'Hara forceps was dangerous and never to be used. The crushable button was good. The Murphy button was best for rapid work, but was liable to be retained as a foreign body in the intestine. The author advocated the use of a cone made of a potato or turnip, through which two long pins were passed transfixing the gut.

Dr. Connell of Leadville, Col., realized that the continuous suture was apt to remain in situ. He had advocated the leaving of the last knot in the lumen of the gut to prevent leakage. The surety of the operation was greater if all the intestinal coats were included in the sutures. Two layers of sutures increased the time of operation and the liability to gangrene.

One Thousand Personally Conducted Cases of Ethyl Chloride Narcosis.—Dr. M. W. Ware of New York has had 95 per cent. satisfactory anæsthesias in his cases by this method. The color was natural, the respiration and pulse but slightly affected by the drug. In 12,000 collected cases there was but one death and the autopsy on this patient revealed a condition of the organs such as would have caused death in any sort of an anæsthesia.

Officers Elected.—Jas. E. Moore, of Minneapolis, Minn., was elected president of the section for the next year, and Dr. John C. Munro of Boston secretary.

SECTION ON OBSTETRICS AND DISEASES OF WOMEN.

Third Day, Thursday, June 12, 1902.

Vaginal Section for the Uncomplicated Symptom of Sterility.—Dr. J. R. Goffe of New York called attention in his paper to cases of sterility in which there were no other symptoms but that of sterility. He divided all cases of sterility in women into extraperitoneal and intraperitoneal, and asserted that sterility might be pathologic or mechanical, or both. He advised the examination of the man before undertaking any radical measures on the woman. Sterility might be present in a woman free from any other symptoms pointing to disease in the pelvis. Under these circumstances he thought the surgeon justified in performing vaginal section and considered that laparotomy should be done to relieve the condition. The author cited four cases in which he performed a vaginal operation and found occlusion of the Fallopian tubes and cysts on the ovaries. The cysts were easily opened and the obstruction in the Fallopian tubes removed. In one case the cervix was infantile; this was dilated and uterus curretted. Of these four cases, two were followed by pregnancy. These cases showed that it was justifiable to open into the peritoneal cavity for the relief of this symptom.

Dr. Watkins of Chicago thought it justifiable to do this operation, yet the examination of the male should be done first before submitting the woman to so severe an operation. He found that after adhesions about the tube had been removed they would again form.

Dr. Merrill Ricketts of Cincinnati considered the paper full of good points. It was the duty of the surgeon to make a thorough examination of the husband. The fimbriated extremity of the tube was, in many cases, bound down and occluded, and pregnancy could not take place. In freeing the opening, he passes a probe into the tube to dilate it and often finds this method will fill a tube diseased with hydrosalpinx. The latter should be drained and the tube thus saved. He preferred conservative surgery in all cases of operation on the Fallopian tubes to a pathological exhibit.

Dr. G. B. Massey of Philadelphia entered a protest against the undue anxiety of the surgeon to perform radical operations; they should use palliative measures and endeavor to restore the functions of the woman by other means.

Dr. Hause of Cincinnati desired to report a case in which he had separated the tubes from the adhesions, with the result that childbirth had followed. He favored the operation, and said that even when a small piece of the ovary was left success was often achieved.

Dr. C. L. Bonifield of Cincinnati objected to the title of the paper because, as there were other symptoms present, there must be some other pathological condition. He hesitated to open the abdominal cavity unless some disease was shown to be present.

Dr. J. R. Goffe, in closing the discussion, said that when the source of the adhesion has been removed, the adhesions themselves would melt away. The inflammatory action, with resulting adhesions, was kept up by the infection. It was wise to make an exploratory incision for the relief of this one symptom of sterility. He de-

[illegible]

The Influence of Prolapse of the Kidney on the Production of Pelvic Disease in the Female.—Dr. A. H. [illegible] of New York [illegible] the evidence of prolapsed kidney after death, the kidney returning to its normal position when the patient was recumbent. The symptoms were marked though pain in the region of the kidneys was rare. The concomitant symptoms of anæmia and loss of flesh were present in the exaggerated form of the prolapse. Manipulation of the kidney produced irritation, and for that reason the use of belts had been found to be objectionable; their constant pressure caused increased flow of urine and irritation of the kidney. The only radical cure was the fixation of the kidney by the usual method. The author considered it advisable to operate early before permanent injury had been done to the pelvic organs and a condition of chronic invalidism had been set up. All these symptoms were averted or might be made to entirely disappear if the kidneys were properly anchored.

Dr. G. B. Massey of Philadelphia opened the discussion. He objected strongly to these operations, asserting that the pressure supposed to be made by a floating or prolapsed kidney was imaginary and that no kidney could make a backward pressure. A falling forward might take place, but not with the results stated by the author. He also vigorously opposed any operative procedure; the knife, he said, was used entirely too much. The symptoms spoken of did not occur. The prolapsed and floating kidney was the result of loss of fat, anæmia, weakness and malaise. He believed a cure could be obtained by the use of nitro-muriatic acid, compound rhubarb pill, stimulation of the abdominal cavity by the galvanic current and general massage.

Dr. Mathews of Detroit asserted that about 40 per cent. have loose or floating kidney, a very small number produce any pelvic congestion. He believed that fixation of the kidney was the only radical method of relieving the condition; yet, as a large number occurred in old women, with relaxed and flabby abdominal muscles, they could not be operated upon.

Dr. Dunning of Indianapolis said that no more difficult question had been presented as to the cause for removal and the effect. The speaker claimed to have been among the first to operate on prolapsed kidney in this country and for a time had done not less than one a day. He had maintained that many symptoms owed their origin to the prolapsed kidney and that fixation of the organ would give relief; but in a short time he had found that the symptoms did not always disappear. Then came a reaction and the operation became a rarity. The use of the pad had then come in vogue. The operation he did not consider dangerous, but the relief was very small unless supplemented by other therapeutic measures.

Dr. C. P. Noble of Philadelphia said the author had mixed up cause and effect. He pictured a woman who had borne several children, having a relaxed abdomen and flabby muscles with a loss of fat, a neurotic temperament and anæmia. Such a woman would most likely have prolapse of the kidney. Improve the general condition and the kidney would return to its normal position. He doubted if there could occur such damage to the kidney from pressure as had been described by the author.

Dr. C. E. [illegible] of Chicago [illegible] the abdominal muscles.

Dr. E. C. K[illegible] of Chicago [illegible]

Dr. Goelet, in closing the discussion, [illegible]

Pathological Condition of the Omentum as a Surgical Factor. The Best Method of Treatment.—Dr. H. O. Marcy of Boston was the author of this paper. He called attention to the uses of the omentum in preventing the loss of heat and injury, helping to support the abdominal viscera, acting as a protection, throwing out lymph cells and preventing infection. It varied in size and in the amount of fatty deposit. Modern surgery had conspicuously demonstrated the physiological importance of the omentum. He believed the pathologic factors incident to the omentum should be kept in mind. The parietal adhesions were the cause of [illegible] and often marked suffering. After operation every rent should be carefully repaired, and the omentum should be spread out and carefully replaced. When these conditions were not fulfilled, a displacement of the omentum into the pelvic cavity might take place and occlusion of the gut result.

Dr. F. H. Wiggin of New York insisted upon attention to the proper technic in operations upon the omentum. He found that by filling the abdominal cavity with saline solution, the omentum could be readily replaced and retained in position and adhesion could be prevented. It was important to put in the stitches before the saline fluid was used, as the necessary movements of suturing would empty the abdomen of fluid.

Dr. Marcy, in closing the discussion, said he considered the suggestion of the last speaker a very good one.

What Cases of Placenta Prævia Can Be Best Treated by Cæsarian Section?—Dr. F. D. Donoghue of Boston, the author of this paper, asserted that the justification for cæsarian section in certain cases could be found in its superiority in saving fetal life without adding to the mother's danger. He did not urge the cæsarian section as a substitute for version or the other forms of delivery except in extreme cases, but he advocated it in cases of placenta prævia centralis occurring in primiparæ and in the presence of severe hemorrhage and rigid os.

Dr. Holmes of Chicago said that the statistics of placenta prævia were valueless; the average practitioner not only did not know how to treat these cases, but did not always recognize them, and a large number were not reported. The proper method of using the tampon should be taught in our schools; for this the speaker considered the best instrument in the hands of the general practitioner. He desired to give one warning, *i.e.*, the danger of infection by the attending physician, which precluded the radical operation of cæsarian section. The death rate after operation was very high, and infection was the usual cause of death. Again, the danger of hemorrhage was still present and as difficult of control as through the vagina. He acknowledged that more babies were saved, but maintained that more mothers were lost.

Dr. G. T. Harrison of New York objected to the operation of cæsarian section in cases of placenta prævia. The life of the mother must be first considered. No operation should be done when infection had taken place as a result of examinations and delay. All efforts should be directed toward saving the life of the mother and ignoring that of the child. By gradual dilatation the danger from hemorrhage had been reduced to the minimum.

Dr. DONOGHUE, in closing, said he valued the life of the mother, but it should be remembered that no child is saved by the other method and all can be saved by the cæsarian section.

The Restoration of the Pelvic Floor.—Dr. C. A. L. REED of Cincinnati read this paper. He spoke of the pathology of injuries to the pelvic floor as consisting of laceration of the superficial structures and the impairment of the muscular apparatus. To be successful the operation for the restoration of the pelvic floor must consist in free dissection of the parts, careful isolation of the injured muscles, a perfect restoration of their integrity, and restoration of the superficial structures.

Drainage versus Radical Operation for Suppuration in the Female Pelvis.—Dr. C. P. NOBLE of Philadelphia compared in this paper the advantages and disadvantages of the two methods. He favored the conservative plan and preferred the vaginal opening as being less liable to infection and presenting the minimum danger of peritonitis. The openings should be free and made from side to side of the walls of abscess or suppurating cavity. The mortality and permanent results of the radical operation for pelvic suppuration were in favor of the vaginal method. The immediate and permanent results of drainage for complicated cases of pelvic abscess were in favor of the radical operation. He was not in favor of using too sharp an instrument; scissors were preferable.

Adenomyomata of the Female Generative Organs.—Dr. THOMAS S. CULLEN of Baltimore demonstrated by lantern slides the three groups into which adenomyomata were divided in the uterus, viz.: (1) Where the uterus preserves a relatively normal contour; (2) When subperitoneal or intraligamentary; and (3) When submucous. He said that adenomyomata of the uterus were derived from the uterine mucosa or from a portion of Muller's ducts. The life history of adenomyomata resembled that of ordinary myomata; they were detected during the child-bearing period of life. In all these cases the prognosis was favorable after operation.

Dr. H. O. MARCY of Boston spoke of the increased vascularity of the uterus in all classes of adenomyomata.

Post-Operative Intestinal Paresis.—Dr. F. H. WIGGIN of New York in this paper discussed that form of intestinal obstruction which takes place after operation, and is usually due to injury of the intestinal nerve supply, or to fermentative or putrefactive changes in the bowel contents. He had found it a fatal complication of the early convalescent period; it should be recognized early and treated promptly. Where the bowels had not moved, there was a sudden vomiting without premonitory nausea, pain, or uneasiness. The prophylactic treatment in all operative cases should be a cathartic every day for three days, and a saline enema the day before operation. When the vomiting began, a seidlitz powder should be given at once, being allowed to mix in the stomach, so as to produce a strong evolution of gas in the stomach. The hypodermic administration of strychnia, 1-30 gr.; atropine, 1-60 gr.; physostigmin, 1-50 gr., was recommended.

Dr. MARCY of Boston thought the method a good one; he would like to see it tried in these cases, as they are both alarming and sudden.

Dr. C. L. BONIFIELD of Cincinnati said he had read a paper on this subject and fully endorsed the author's views. In his cases he had used strychnia. The cause of the condition was apparently to sepsis, and the exposure of the bowels to cold during the operation. He did not believe in the use of salines before the operation, but he gave compound extract of colocynth seven days before.

Dr. WIGGIN, in closing, said he did not give salines by the mouth before operation; the saline enema given the day before was, however, very useful. On the postmortem examination no sepsis was found. Action must be taken promptly. In one case the seidlitz powder had been given through a stomach tube; there was no nausea or colic—only a sudden regurgitation. When patient refused food, a Seidlitz powder should be given.

FOURTH DAY, FRIDAY, JUNE 13.

Critical Remarks on the Methods of Operation in Vogue for Cystocele with and without Prolapse of the Uterus.—Dr. C. O. THEINHAUS of Milwaukee proposed in this paper manifold methods for the radical cure of cystocele with or without uterine prolapse. A very small number of operations had fulfilled the promises of their originators that there would be no recurrence. The most rational and best methods make use of the uterus as a supporting agent for the bladder, thereby blocking its further descent.

Dr. W. T. METCALF of Detroit considered it more satisfactory to remove the uterus, as all these cases occurred in old women and after the child-bearing period.

Dr. BOYD of Philadelphia considered prolapse of uterus as a cystocele and believed in treating it as such. He removes the cervix and suspends the uterus, as this gives better results.

Dr. C. L. BONIFIELD of Cincinnati thought prolapse was a hernia occurring late in life, after the birth of many children and consequent upon abdominal relaxation and loss of fat. He found general tonics of service. The operation of removal of the cervix and suspension of uterus he considered valuable, but much could be done by rest, tonics and massage.

Dr. DUNNING of Indianapolis thought the cases should be divided into two classes, women who had passed the menopause, and those capable of bearing children. In the first, the uterus should be removed. In all cases he repaired the perineum, and attached the uterus to the abdominal wall.

Surgical Treatment of Internal Hemorrhoids.—Dr. WM. F. METCALF of Detroit spoke of the effects of internal hemorrhoids on women, and commented on the similarity of the reflex phenomena of internal hemorrhoids to those produced by pathologic changes in the generative organs. He believed the operation was best done by gynecology, and should be done at the same time as the work upon the uterus and its adnexa. He objected to the ligature and tying *en masse*, with its resulting sloughs. He operates by cutting away the vein extremities and redundant tissue and leaves the denuded surface uncovered. When complicated with much redundant tissue and prolapse the diseased membrane should be amputated.

Officers Elected.—*Chairman*, A. Palmer Dudley of New York; *Secretary*, C. L. Bonifield of Cincinnati.

SECTION ON MEDICINE.

THIRD DAY—THURSDAY, JUNE 12.

The Occurrence of Gout in the United States, with an Analysis of Thirty-six Cases.—Dr. THOMAS B. FUTCHER of Baltimore read this paper and summarized as follows: (1) Gout in the United States is undoubtedly more common than is generally supposed; (2) Out of 13,400 medical cases admitted to Dr. Osler's medical wards in the Johns Hopkins' Hospital during a period of thirteen years there were thirty-five gout cases, or 0.24 per cent. of the total number of cases. For the same number of years at St. Bartholomew's Hospital there were 116 gout cases out of a total of 31,100 medical admissions, or 0.37 per cent. of the cases. Thus among hospital patients gout is only about one-third more frequent in London than in Baltimore; (3) All the thirty-six cases were in white males. The largest number of cases occurred in the fifth decade. Twenty-seven of the patients were native born Americans; (4) The majority of the cases appeared to have earned rather than have acquired their gout. Alcohol and lead seemed to be the most potent predisposing etiological factor; (5) Thirty-three of the thirty-six cases had reached the chronic stage before they came under observation. In seventeen of the cases tophi were present; (6) Among the more interesting complications may be mentioned three cases of gouty [illegible] of [illegible] one of [illegible] symptoms simulating [illegible] obstruction. (3) There was evidence of disease of the [illegible] of the majority of the cases. [illegible] occurred in [illegible] and [illegible] in twenty-three instances, the [illegible] in twenty-three cases and [illegible] by the [illegible] Mayo [illegible]. [illegible] of the cases were [illegible] as [illegible]. The [illegible] This series illustrates the great importance of examining the [illegible] and the vicinity of the [illegible] for the presence of [illegible] in all cases of [illegible].

Syphilis of the Liver.—Dr. Charles G. [illegible] of [illegible] read this paper. He said that although the chief pathological changes induced by syphilis of the liver appeared to have been closely studied and classified, the [illegible] with instances of undoubted syphilis in which there developed hepatic [illegible] that no [illegible] as to the precise character of the morbid change that classification has to be abandoned. There is no fundamental difference between the pathology of congenital syphilis and that of the acquired disease. In either case we may have first the diffuse hepatitis or parenchymatous degeneration, to be succeeded by the ingrowth of fibrous tissue; these changes are probably due to the local effect of the specific toxin rather than to local infection. Second, we have gummata occurring as large tumors, in scattered masses, in miliary granulomata, or in the budding stage as mere aggregations of [illegible] cells; these lesions appear to be the outcome of [illegible] of tissue from the local action of microorganisms. In some cases the liver is apparently invaded through the lymphatic system, sometimes by the route of the peritoneal cavity, in other cases the disease [illegible] in the bloodvessels, or by obliteration of some of the portal branches, or distributions of the hepatic artery. He then cited illustrative cases showing the conditions under which hypertrophy or deformity of the liver may occur besides pain, ascites, jaundice, and other symptoms commonly associated with affections of the liver other than syphilis. It is generally conceded that [illegible] syphilitic lesions of the liver occur only in the late stages of the disease. With the exception of perihepatitis and lymphatic involvement, he was sure that this was true. The last named lesion he had seen at a comparatively early period. Besides this, he was [illegible] that in the early stages of the affection the liver was [illegible] moderately enlarged, somewhat tender, and [illegible] poorly. Very likely this is the immediate result of a constitutional disturbance, i.e., the [illegible]. In conclusion, he expressed the opinion that [illegible] complications are more common in syphilis than one is likely to infer from the literature on the subject. The subject has not received the [illegible] of consideration that its importance seems to warrant.

The Treatment of Croupous Pneumonia.—Dr. E. Fletcher Ingals of Chicago read this paper, in which he gave an analysis of the cases treated in Cook County Hospital for the fifteen months preceding April 1, 1902. He reviewed the literature on the subject extensively, but presented no new ideas upon the subject. He said, in substance, that the frightful mortality in this disease had led our best pathologists to become therapeutic nihilists. Few physicians will admit that their efforts to mitigate the severity of pneumonia are of no avail. However, there are some remedial agents which deserve consideration. The patient should have abundant nourishment, but the stomach should not be overloaded. The cotton jacket may be applied. Pain may be relieved by hot or cold applications, by strapping, or by drugs. He recommended [illegible] or hyoscyamus for cough. The temperature could be controlled by various means. He spoke of the action of various stimulants and anti-[illegible] [illegible]. In these cases in which the [illegible] did not [illegible], he thought that the [illegible] could be [illegible] by the administration of the [illegible] of [illegible] and possibly [illegible] such as acetate of potassium.

An Analysis of Sixty-five Cases of Gastroptosis.—Drs. T. Duncan [illegible] and [illegible] P. [illegible] of Philadelphia presented this paper. The conclusions reached were as follows: (1) Gastroptosis is much more common than might be inferred from the meagre reference made to it in a majority of the text-books upon general medicine. By [illegible] symptoms of gastric motor insufficiency its presence is almost constant, and it is probably the most important factor in the causation of [illegible]. It is much less frequent in men. (2) The occurrence of gastroptosis is not confined to any particular age or class of individuals. There are no causative factors common to all cases, and no explanation of its etiology hitherto given is broad enough to call it satisfactory, if we except the theory of congenital predisposition which is entirely hypothetical; (3) the position assumed by the stomach in all of their cases was vertical or subvertical. Total descent was not observed and probably is extremely rare. Some dilatation of the pyloric extremity was always present. When the dilatation affects the pyloric end alone it may perhaps safely be assumed that the dilatation is secondary to the descent of the pylorus. In general dilatation and gastroptosis it is probable that the displacement is secondary to the dilatation. The data in regard to the position of the stomach were obtained in every case by inflation with air through the stomach tube. The colon was inflated through the rectum. (4) The transverse colon invariably shared in the displacement, assumed the "M" or "V" shape, and when inflated by air, was in close contact with the greater curvature of the stomach. The hepatic flexure may not be displaced or may sink to the level of the umbilicus. The splenic flexure lies behind the stomach and eludes demonstration; (5) The right kidney was movable in 60.9 per cent. of the cases. The left kidney rarely showed abnormal movability and the spleen in but one case. The fact that the liver was observed to be unduly movable and sagging downward in three of the six cases operated upon suggest that ptosis of this organ may elude our methods of physical examination, and be more frequent than is usually supposed; (6) There is no condition of the gastric contents peculiar to gastroptosis. Absence or diminution of the free hydrochloric acid is the rule. In a few cases the amount was normal. Hyperacidity was rare and usually occurred in cases where general dilatation existed, and when there was a strong neurotic taint. (7) There were no characteristic changes in the blood or urine. (8) The subjective symptoms were those of gastric motor insufficiency and were of a mild grade in cases of primary ptosis, but more severe where general dilatation existed. Pain was present in the upper abdominal region in about half and in the lumbar region in a quarter of the cases. (9) The same causes that produced neurasthenia appeared to favor the development of ptosis of the abdominal viscera. When the two conditions are established they probably react upon each other deleteriously, but clinical evidence tends to contradict the theory previously widespread, that they have a direct causative relation.

The Etiology of Acute Articular Rheumatism.—Dr. George W. Webster of Chicago presented a paper on this subject and offered the following conclusions: (1) Many organisms produce arthritis. (2) Probably all cases of acute articular rheumatism are due to infection. (3) Probably all organisms known to cause either acute articular rheumatism or other forms of arthritis, also give rise to other pathological conditions as well. (4) It would thus seem to be not merely a local infection or inflammation, but a general infection, the commonest seat of the principal lesion being the joints, but also involving the heart, both endocardium, pericardium, and muscle, occasionally the meninges and other structures, and caused by a diplococcus circulating freely in the blood. The diplococcus seems to be merely a germ capable of causing a widespread inflammation, and the joints are included in its sphere of action. Just as in pneumonia, we may have a general infection with local manifestations or inflammatory reaction in the meninges, the pleura, the endocardium, pericardium, post-nasal space, peritoneum, lymphatics and lungs, the latter being probably the usual site of the localizing inflammation; (5) It is quite possible that there is some hereditary diathetic or constitutional peculiarity, the nature of which is completely unknown to us, which may favor infections in general, and possibly that of rheumatic infection in particular; (6) That there may be varying degrees of susceptibility depending upon exhaustion, depressing influences, as cold and the like, seems reasonable. These are the occasions and not causes. They favor, but do not cause; (7) That susceptibility varies greatly there can be no doubt. Whether this depends upon alkali tension has not yet been demonstrated, but seems plausible on the ground of variation in the bactericidal action of the blood. This may explain the value of alkalie in the treatment of rheumatic affections.

Etiology and Prophylaxis of Cardiac Manifestations of Articular Rheumatism.—Dr. Joseph M. Patton of Chicago read this paper. He said that it had been admitted that many of the so-called hereditary diseases of the heart were probably of rheumatic origin, while it was generally conceded that those cardiopathies of early life which obtain with the entire absence of clinical history, or, at least, an indefinite mention of "growing pains," were of rheumatic origin. In several hundred ambulatory cases of acute and chronic disease of the heart observed during the last ten years, fully 30 per cent. failed absolutely to give any history of rheumatic manifestations, though usually some such history could be traced in the parents or other members of the family. Sansom believed that all cases practically of heart disease in individuals under thirty-five years of age were rheumatic, and that practically all fetal endocarditis was rheumatic. In a certain proportion of cases there appears a degree of myocarditis which cannot be explained by extension of inflammation or by embolic or other direct infective processes, and we must assume with Hanot that toxins are able of producing acute inflammation of the heart. Pericarditis, according to Baumgarten, occurs in about one-third of the cases of acute rheumatism. Of 150 cases of rheumatic heart disease reported by Lees, the pericardium was uninvolved in only nine instances. Twenty per cent. of Sibson's cases of acute rheumatism were complicated by pericarditis. Latham gave 7.5 per cent., and Chambers and Ormorod gave 13 per cent. and 71.7 per cent., respectively. Acute rheumatism is generally conceded to be the most frequent cause of endocarditis. Of Sibson's cases, 325 in number, 107 had endocarditis alone, and fifty-four endopericarditis. The occurrence of acute myodarditis in connection with rheumatism is generally admitted. With the treatment of acute rheumatism he emphasized his belief in the importance, so far as voiding heart complications were concerned, of early control of the condition, as shown by mitigation of the joint symptoms and subsidence of the fever, and he expressed his conviction that this was best obtained by the temporary employment of pure salicylic acid in sufficient dosage to produce relief of pain and fever, with sweating and more or less depression, to be followed by sodium salicylate combined with the alkaline diuretics. He believed the most effectual measure locally was the application of cold to the præcordium. It should be applied continuously. Hot applications have an analgesic effect and are more readily allowed by children. Their effect on the inflammatory condition was decidedly less than cold. Aconite had a distinctly beneficial effect in quieting the heart and slowing its action. In the earlier excitable stages aconite, combined with sodium bromide, would act to advantage.

Review of the Cases of Acute Articular Rheumatism in the Medical Clinic of the Johns Hopkins Hospital.—Dr. Thomas McCrae of Baltimore said that in a period of thirteen years there were 270 cases of acute articular rheumatism. This represented an admission of 294 cases which gave a percentage of two of all medical admissions. Of these 198 were males and seventy-two females; 223 were whites and forty-seven were colored. The largest increase was in the mid-decade, with the second decade coming next. The oldest patient was aged sixty-six years. The largest number occurred in the first half of the year and 55 per cent. in the months of February, March, April and May. September was the month with the fewest cases. There was a family history of rheumatism in 25 per cent. and of tuberculosis in 14 per cent. There was a previous history of rheumatism in 45 per cent., of tonsilitis, however, only in 4 per cent., and of chorea in 3 per cent. Nearly 40 per cent. gave a history of the more or less constant use of alcohol. In about 75 per cent. the age of the first attack was below thirty, the largest number (36 per cent.) being in the second, and only 8 per cent. in the first, decade. There was a history of exposure to cold, wet, etc., in 12 per cent. of all the cases. Arthritis was the most predominant symptom in onset in over 80 per cent., but in seventeen cases a chill occurred at the onset, in ten tonsillitis, and in single cases various conditions, among others trauma. The arthritis was, of course, an inevitable feature, more often in the legs than in the arms, the knee-joint being involved in over 50 per cent. In all the joints of the lower extremities both joints, *e. g.* both knees, were effected more frequently than one only, while the contrary was true in all the joints of the upper extremity. The average duration of fever was twelve days. There were not any cases of hyperpyrexia. About 30 per cent. of the cases had fever above 103. The heart sounds were clear throughout in 38 per cent.; definite organic lesions were present in 32 per cent., and the remaining cases were more or less doubtful. Of these seventy-eight doubtful cases, in eighteen there were murmurs present during the attack which disappeared. In the remaining sixty there was in all a systolic murmur of varying distribution, in a large number at the apex only, of soft quality and not transmitted. The heart condition in other ways normal. In nine cases the murmur disappeared under observation, all at the apex. In five of these the murmur was apparently due to an organic lesion, the other four being doubtful. The age at the first attack in reference to the cardiac condition showed that, of the patients who had the first attack below the age of twenty years, 45 per cent. had a definite lesion, while of those over the age of twenty at the first attack only 21 per cent. had a lesion. This pericarditis occurred in 6 per cent., and with the first attack in only three of the sixteen patients. The time varied from the fifth to the sixty-first day. The rub persisted for a period of from five to eighteen days. There was associated delirium in one instance only. The fever in the majority of the cases was not high, only three being above 103°. There was a leucocytosis of 15,000 to 25,000 in all of the seven cases in which counts were made. There was associated endocarditis in eight cases, doubtful in four cases, and no evidence of it in four. Effusion occurred in two cases, adherent pericardium in three, and death in three. The pulse rate of the series showed that in only 41 per cent. was the pulse raised over 100, only in thirteen cases, or 6 per cent., was it over 120. The urine was clear throughout in 48 per cent. Albumin was found on admission only, or once in 34 per cent., occasionally in 5 per cent., and throughout in 11 per cent. A positive diazo-reaction was given in three out of ninety-one cases. The average percentage of hæmoglobin in seventy-seven [illegible] were negative, the red cells in [illegible] were 4,[illegible], and the [illegible] in [illegible] were [illegible]. The average [illegible] showed nothing unusual. The average stay in the hospital was twenty-six days, and the average duration thirty-eight days. Cultures from the blood, [illegible], and [illegible] were negative throughout. Death occurred in [illegible] of the [illegible], all having [illegible].

The Salicylates in Acute Rheumatism.—Dr. James J. Walsh of New York read this paper. He said that it was generally conceded that the salicylates constitute the most satisfactory remedy for acute rheumatism, though they can no longer be considered a specific for rheumatism in the sense that quinine is a specific for malaria. The salicylates do not affect secondary infectious complications of [illegible] due to pus cocci, [illegible], or other infections, nor the arthritis due to the gonococcus. Rheumatic cases that are not influenced by the salicylates should be suspected to be dependent on some other etiology other than that of simple acute rheumatism. In regard to the dosage of salicylates he said that they were ineffective unless employed in large doses, from 90 to 120 grains per day. Many patients cannot stand this amount of the drug. Certain nervous individuals develop neurotic symptoms that may proceed to delirium. Again some patients will not tolerate salicylates, a disturbance of the digestion further adds to the impoverished condition of the system. The salicylates are distinctly irritant to the kidneys and should not be given in cases of nephritis. It will react to increase the anæmia and make heart complications more serious. In certain cases there is a development of salicylic dyspnœa, and if breathing becomes very rapid it must lead to the substitution of some other remedy. The form of salicylates that are used is a matter of clinical observation that each physician must decide for himself, but the criticisms are sufficiently numerous and authoritative to make it clear beyond a doubt that the subject is well worthy of consideration. He said with regard to the time at which the salicylates should be administered that there is some variance of opinion, but as the temperature of rheumatic patients is higher in the afternoon and evening and they are almost sure to be more uncomfortable and to present more symptoms of the affection at this time, it may be better to administer them so that the daily dose is given before four o'clock in the afternoon. In heart complications it seems advisable that alkalies should always be used in conjunction with the salicylates. Sufficient of the alkalies must be employed to render the urine alkaline. They are not employed with any thought of the presence in the blood either of uric acid or lactic acid, but entirely on clinical grounds. There is no doubt that the salicylates relieve the pain, lessen the fever, diminish the restlessness, and so make the patient very comfortable. There is considerable doubt, however, as to whether the remedy affects the rheumatic process itself. Hyperpyrexia is one of the complications that is undoubtedly much less frequent in acute rheumatism than before the introduction of the salicylates. As the salicylates are not specific for rheumatism and the beneficial effects obtained from them may also be derived from cognate coal-tar products, antipyrin has been very extensively used in Germany as a substitute. Like the salicylates antipyrin must be used in large doses. From 60 to 90 grains per day are employed for three or four or more days, until the painful symptoms of the rheumatic condition have subsided. Phenacetin in similar doses as those mentioned for antipyrin have also been employed with good results. Either of these drugs may prove effective when the salicylates fail.

The Influence of Ozonation upon the Blood.—Dr. G. Lenox Curtis of New York thought that the profession at large had been slow to appreciate the importance of a thorough knowledge of the blood as an aid in diagnosis. He stated that unmistakable indications of disease are often recognized in specimens of fresh blood of which photographs may be made. These should be attempted only within a few seconds after the fluid has been drawn, as even a brief exposure of the specimen to the air may cause failure. This method affords knowledge of disease early and enables the physician to institute treatment before ordinary symptoms are clearly established. The author held that good health was preserved when normal conditions of blood, fibrin, and [illegible] were conserved. When the examination reveals the presence of [illegible] or an abnormal state of the blood the fluid must be restored by oxidation. Ozone, the "Magnetic" principle of oxygen, can be produced by means of a high tension electric machine and forced into and through the body to such an extent as to destroy the [illegible] in the blood and other tissues. The machine for generating the current was described in the *New York Medical Journal*, January 18, and February 1, 1902. No shock is experienced by the patient. The machine is used in connection with a cabinet fitted with a glass [illegible] above and below which are clusters of incandescent lights. Reflectors are so arranged as to subject every portion of the patient's body to the effects of light rays. The treatment consists of a twenty to thirty-minute period in the cabinet, during which the patient inhales nascent ozone, while his body is exposed to the heat and light-rays. At the same time the extremely high tension current is passed through the body. This procedure brings on profuse perspiration, after which a shower and massage of the diseased area with the electrode complete the seance.

Officers elected for the ensuing year: *Chairman*, Dr. W. S. Thayer of Baltimore; *Secretary*, Dr. J. B. McIlroy of Mississippi; *Delegates*, Dr. J. M. Anders of Philadelphia for one year and Dr. C. G. Stockton of Buffalo for two years.

SECTION ON DISEASES OF CHILDREN

First Day, Tuesday, June 10

Chairman's Address.—The meeting was called to order by the chairman, Dr. H. M. McClanahan of Omaha, Neb., who then delivered his address. His topic was "The Lessons from Pediatric Literature," and his address comprised a brief review and classification of the 477 purely pediatric articles which had appeared during the past year. His conclusion was, that while this literature gave evidence of a general advance in pediatrics, it did not appear to be up to the standard reached in other departments of medicine.

Tuberculous Peritonitis.—Dr. Thomas Morgan Rotch of Boston, Mass., presented this paper. He said that the reason that laparotomy had been successful in some cases of tuberculous peritonitis was still not definitely known. Most commonly tuberculous peritonitis was secondary to tuberculosis of the mesenteric nodes, or of the intestine, lungs or lymph nodes elsewhere. It might arise in the course of various infectious diseases, especially the exanthemata. The ascites might be serous, seropurulent or purulent in character. The form known as fibrous was essentially chronic, and did not exhibit much tendency to break down. In another variety there were large tuberculous deposits associated with caseation and breaking down. In these cases there was usually also involvement of the lungs. The symptoms of tuberculous peritonitis in infancy and early childhood are exceedingly obscure. If the temperature were elevated to 102° or 104° F., the difficulties were increased. If, however, the temperature remained between 100° and 102° the tuberculin test was available. It was of value, although its negative evidence was not decisive. Having determined the presence of tuberculous peritonitis one should next ascertain whether or not there was tuberculosis elsewhere in the body. A swab culture from the pharynx would sometimes serve to detect the presence of the tubercle bacillus. Leucocytosis might or might not be present. In infants there was apt to be a miliary tuberculosis in the course of a general tuberculosis, and not as a rule associated with abdominal symptoms. If there was a localized tuberculous process in the peritoneum, chronic in its course, it was especially suitable for treatment by laparotomy. The most favorable form was that in which there was miliary tuberculosis of the peritoneum associated with ascites. In cases of fibrous tuberculous peritonitis the association of ascites improved the prognosis. Laparotomy could rarely be resorted to advantageously in the first year of life. In the third, or ulcerative form of tuberculosis of the peritoneum there was usually evidence of tuberculosis in the bronchial nodes or in the lungs. The danger of a localized tuberculosis becoming disseminated was a real one; hence, it was better to operate before such dissemination took place. An exploratory laparotomy in the early stage of the disease was not especially dangerous. From 1884 to 1902 the total number of cases admitted to the Children's Hospital, Boston, with a diagnosis of tuberculous peritonitis was sixty-one, thirty-nine of them being boys. After the age of one year this affection became more common, and was most frequent between the ages of two and four years. The average duration of the cases before admission was three months There was a family history of tuberculosis in 30 per cent. of the cases. Abdominal tenderness was generally absent. The movements of the bowels were not significant. The temperature was irregular, and, as a rule, slightly elevated. The pulse was more rapid than normal, but varied within wide limits. White blood counts had been made in twenty-three cases, and gave an average of 16,435, the maximum being 44,000 and the minimum 5,400. Thirty-seven per cent. died in the hospital after operation. Of the eighteen autopsies, in not one were the lessons of tuberculosis limited to the peritoneum. Seventeen cases showed tuberculosis lesions of the lungs, and 12 cases tuberculous lesions of the brain or meninges. Six of the cases proved to be practically inoperable because of adhesions to the abdominal wall and elsewhere, though a limited number of adhesions did not prevent a successful result. Tuberculosis of the mesenteric glands did not preclude a successful issue. The presence of tuberculous ulcers of the intestine was obviously an unfavorable sign. Fourteen of the successful cases had been traced, and eleven were known to be well at the present time; two had died, and one was suffering from a relapse.

Dr. J. M. Dodson of Chicago expressed his appreciation of the apparent reaction in favor of a more frequent resort to the tuberculin test as a means of diagnosis. This was a diagnostic aid of no mean importance. He thought the use of the *x*-ray in these cases held out some hope of therapeutic benefit. In a number of cases of tuberculous peritonitis in adults at the Presbyterian Hospital, Chicago, the *x*-ray had been used with gratifying results. There had been a subsidence of tenderness and pain, and a disappearance of the effusion and fever. He would suggest the use of this agent in those cases in which operation was contraindicated.

Cerebrospinal Fever.—Dr. J. P. Crozer Griffith of Philadelphia read this paper. He said that the disease was not very common in this country as compared with other infectious diseases, and the symptoms varied greatly in different epidemics and in the same epidemic. The chief types of the disease were: (1) The ordinary; (2) the malignant; (3) the mild; (4) the abortive, and (5) the chronic. Herpes was frequently seen and petechiæ often developed. In the malignant form the disease begins with extreme suddenness, and collapse and coma very soon develop, death occurring in a few hours. In the mild form, the patient hardly needs to go to bed, and the stiffness of the neck may be hardly perceptible. In these mild sporadic cases the diagnosis is practically impossible. He had rarely seen greater emaciation than in connection with this disease. In some cases the effect of the germ appeared to be localized more upon other organs than the brain and spinal cord. The author then reported three family epidemics in order to illustrate the tendency to variation. The third epidemic exemplified the relation of cerebrospinal meningitis to pneumonia—an interesting fact because of the well founded suspicion that these two diseases are due to the action of the same germ.

Dr. C. F. Wahrer of Madison, Iowa, reported a case, seen in consultation, in which he had felt justified in changing the diagnosis from typhoid fever to cerebrospinal fever because of the spinal rigidity and the application of Kernig's sign. The subsequent history had proved the correctness of his diagnosis.

Dr. I. A. Abt of Chicago, suggested the propriety of isolating cases of cerebrospinal fever, and reported an obscure case in which he had derived assistance both from lumbar puncture and the Widal test.

Dr. T. M. Rotch of Boston spoke of the pressing need, particularly in private practice, for an early and accurate diagnosis and prognosis in these difficult cases. After an extensive experience with lumbar puncture, he stated his belief that it is an exceedingly important procedure, and one which he had never seen do any harm. Often the finding of the diplococcus intracellularis in the fluid removed by lumbar puncture would at once clear up the diagnosis and indicate the serious nature of the malady. As the Widal reaction might persist for many months after an attack of typhoid, the presence of this reaction and of a clear fluid by lumbar puncture without evidence of meningitis, would point pretty surely to the diagnosis of typhoid fever with only the symptoms of meningitis arising from the toxins of typhoid. The bearing of such findings upon the prognosis was obvious. In very early life typhoid fever is a benign disease, and cerebrospinal meningitis an exceedingly dangerous one. So far, however, lumbar puncture had not apparently been curative, but he would advise a more general resort to this measure in the severe chronic cases characterized by stupor and a tendency to become idiotic. The fluid should be allowed to flow out under its own pressure and not be aspirated. Usually the favorable cases of cerebrospinal meningitis were those which last until the second or third week. If the disease lasts longer than this, the prognosis becomes more gloomy, not that the child is likely to die of the acute process, but because the disease is becoming chronic, with all the mental impairment and other damage that this implies. However, even some of these very chronic cases eventually recover, and it was well to bear in mind that there is a much better opportunity for recovery in this disease than in any other form of chronic central nervous disease.

Dr. Thomas J. Acker of Croton-on-Hudson called attention to the fact that, in fifteen or twenty cases that he had seen in general practice, the cerebrospinal meningitis had been ushered in very suddenly in the course of the night. He had found three remedies useful in this disease, viz., bromide of potassium, tincture of gelsemium, and Fowler's solution of arsenic.

Dr. Griffith, in closing, said that he was extremely skeptical as to the value of Kernig's sign, as he had found it repeatedly absent in cases of meningitis of various forms. Its absence was no proof that the affection was not a meningitis. He did not think there was any more occasion to isolate cerebrospinal fever than typhoid fever. The degree of opisthotonus commonly observed in cerebrospinal disease was striking. He had never seen more than temporary relief from lumbar puncture, but this was certainly often quite marked, so that one was sometimes justified in repeating this procedure solely on this account.

A Case of Typhoid Fever in an Infant.—Dr. E. F. Brush of Mount Vernon. N. Y., reported this case, after pointing out that the literature seemed to indicate the great rarity of typhoid fever in infants under one year old. His own case occurred in a family of nine persons, two adults and seven children domiciled in a log house of two rooms in the backwoods of Maine. The family was completely isolated. The source of contagion was a polluted spring. The mother had nursed an infant of six months when she herself was attacked, and continued to do so for about one week. He wished to call attention to the fact that this infant did not contract the disease until it drank the polluted water [illegible] bottle, and that then it contracted the disease just as did the others in the family.

Dr. A. C. Cotton of Chicago said that within the past few years a large number of cases of infantile typhoid fever in infants and young children had been reported, and he believed they reacted as readily to the Widal test as did adults.

Dr. J. P. Crozer Griffith of Philadelphia said that there were on record 418 cases of typhoid fever in children of two years and a half and under, of which about 186 were in the first year of life. He had seen typhoid fever in infants of three, seven and nine months.

Dr. Cotton added that it had been conclusively demonstrated that breast-fed infants are not exempt from typhoid fever and that the fetus may contract the disease *in utero*.

The Clinical Results of Serum Therapy.—Dr. Edwin Rosenthal of Philadelphia laid down in this paper the general rule that a therapeutic serum should be used from the onset of the disease until the time that the blood has become changed by the products of disease—in other words these sera are intended for the treatment of disease and not of its results.

SECOND DAY.—WEDNESDAY, JUNE 11.

Acute Gastroenteritis of Infants.—Dr. Margaret Taylor Scott of Springfield, Ill., pointed out in this paper the effect of hot weather in causing depression of the vitality and producing thirst, with the consequent temptation to over-feeding. The chief germs found in the stools of children suffering from acute gastroenteritis are saprophytic. The early symptoms are fever, prostration, vomiting and abnormal stools; hence, the only doubt as to the diagnosis arose from the possibility that these symptoms were indicative of one of the exanthemata. The chief means of prevention were keeping the child cool and clean and supplying wholesome food in appropriate quantity. When the attack had already developed, all milk food should be stopped, and a purge should be given, and if the stools are offensive, it was well to flush out the colon. As a substitute food she preferred one of the preparations of peptonized beef, as she had never seen any laxative effect from this diet and no irritation of the kidneys. The importance of giving plenty of pure, cool water was insisted on. Bismuth should be administered in quantities sufficient to produce black stools. Opium should be given sparingly and with great caution. A change of air often worked wonders. The after-treatment was important, and consisted largely in very careful regulation of the diet, the resumption of milk diet being gradual.

Milk Idiosyncracies in Children.—Dr. Louis Fischer of New York read this paper. He said that a great many children digest milk with great difficulty, that fever often resulted from the fermentative changes brought about by the undigested milk. Hand-fed and marantic children evidently require a different food from healthy children. The author cited some instances in which whenever milk was given it produced gastric and intestinal disturbances and at times high fever. Large cheesy and foul-smelling curds were discharged by the stomach washing and colon flushing. Such children were very restless at night owing to the fermentative changes produced by the milk, and their sleep became more natural on withdrawing the milk. These children bore well meat juice and soup made from meat and vegetables, and also the white of egg given with water and with tea. Occasionally one met with infants who did not tolerate even breast milk. Dr. Fischer reported excellent results from the use of what he called Keller's malt soup. It is made as follows: To about two ounces of wheat flour add eleven ounces of milk. The wheat flour should be thoroughly soaked and rubbed through a sieve or strainer. Into a second dish put twenty ounces of water, add three ounces of malt extract and dissolve at a temperature of 122° F. Then add about two drachms and a half of an 11 per cent. solution of potassium carbonate. Finally, mix all of the above ingredients and boil. The approximate composition of this food is albuminoids 3 per cent., fat 1.2 per cent., and carbohydrates 12.1 per cent. The object of the wheat flour was to counteract the tendency of the malt to cause diarrhea, and the alkali was added to neutralize the large amount of acid generated in sick children. Budin had emphasized the importance of giving fat rather than reducing its quantity in poorly nourished children, and had cited the assimilability of his cream mixture and of breast milk in underfed children as proof of the truth of this assertion. Dr. Fischer said that he had used this malt soup with great success in the treatment of cases of marasmus, and advocated its use as a temporary substitute when milk would not agree, and as a permanent substitute for milk when disagreeable symptoms were constantly encountered. The food should be prepared by a competent chemist in a laboratory. The author cautioned against making the mistake of rashly assuming that a child could not assimilate milk readily. To this end he advised that the physician should ascertain the source of the milk, its age and the fact that it had an alkaline reaction. When the milk was found to disagree it should be diluted, and only after constant watching of every minute detail should the conclusion be reached that the little patient is really one of those presenting an idiosyncrasy to milk.

Improvement of Breast Milk and Prolongation of Lactation.—Dr. Thomas S. Southworth of New York contributed this paper. He said that at times accurate chemical analysis of breast milk would prove of value, but there were simpler ways of judging of the quality of the milk. The improvement of breast milk was simple. The normal specific gravity of such milk was 1031, and a high fat content lowered the specific gravity, hence, a high specific gravity with a high fat percentage indicated an excess of proteids. If the breast milk were scanty or it disagreed with the infant, it was fair to assume that the mother was out of health, anæmic or constipated; that she got too little fresh air or exercise; that she took too little fluid of the right kind, or that she was not on a plain, sensible diet. A few well-directed questions, therefore, should put the physician in possession of the necessary facts for an intelligent and successful supervision of the nursing mother. It should be borne in mind that thirst was no guide to the quantity of fluid the nursing mother should take. Milk was the most important fluid for her to drink, and she should take a quart or more in the twenty-four hours. Thin corn-meal gruel, made of yellow meal cooked for a long time, and thin enough to be drunk freely was another useful and most important article of diet. It was infinitely superior to oatmeal gruel. The nursing mother required on an average at least three quarts of fluid daily. Cocoa, made by prolonged boiling of the cracked cocoanut, was an excellent beverage, and should be used as a substitute for tea and coffee. Tea should be prohibited, and the elimination of this from the diet was in itself often sufficient to correct the abnormality of the lacteal secretion. Beer had but little nutritive value and often disturbed the infant. With the diet already given, beer and malt extracts were rarely required, and were best avoided. Anæmia should receive careful consideration. It existed, as a rule, after childbirth, and was commonly neglected by the physician. This condition of the blood should be counteracted by the use of Blaud's pills and cascara. If with good, regular hours of nursing the infant vomited and had disturbed stools, the deduction was that the proteids of the breast milk were too high. Nothing was so effective for the correction of this as walking, the distance being increased each day. Such exercise should, of course, always fall short of actual fatigue, and when even a short walk caused fatigue riding could be substituted for a time to advantage. The author was convinced that in the majority of cases in which the breast milk gives out in the first few weeks this could be prevented by proper feeding and management of the mother. Where it was necessary to build up the mother by iron, fresh air and exercise, the failure of the infant to gain in weight for a time should not cause anxiety, provided the weight did not diminish. If the child lost weight steadily, supplementary feedings must be employed. Bad nursing habits and faulty maternal diet were the chief causes of trouble at the end of the third or fourth month. If the weight of the child corresponded fairly to the age, one might feel quite sanguine in overcoming the difficulty with proper coöperation on on the part of mother. Even if the baby vomited and had bad stools, regulation of the hours of nursing and attention to the diet and hygiene of the mother would usually correct the difficulty. If the child's condition were already poor, and it was losing weight, the child should be given a suitable quantity of properly modified cow's milk after each scanty nursing, or else the bottle substituted for certain nursings. The latter method was probably the better plan. If three or more bottles were required, the child should be given both breasts at each nursing, otherwise the supply of breast milk would rapidly diminish. We should steadfastly combat the old and erroneous notion that scanty breast milk is bad breast milk. The physician who, without serious consideration, ordered the withdrawal of breast milk and exclusive bottle feeding assumed a grave responsibility, because of the undoubtedly greater mortality among children artificially fed.

Infant Feeding.—Dr. ALEXANDER MCALISTER of Camden, N. J., read this paper. He pointed out the significance of the fact that one-tenth of all children do not live a month and one-third do not reach the age of three months. We should not lose sight of the fact that cow casein is not human casein and cannot be made so by any known means available for general use. Much of the so-called modification of milk failed because it simply changed the relative proportions of the chief constituents without rendering them more digestible. The deplorable pseudo-scientific statements of the manufacturers of proprietary infant foods were largely responsible for the growing notion that the modern artificial feeding of infants is really an improvement upon the time-honored rearing of infants at the breast. It was well known among pediatricians that gastro-enteritis, scurvy, and rickets, are specially frequent in artificially-fed infants, but the people generally do not know or fully appreciate the portentous lesson taught by statistics, *i. e.*, that the percentage of deaths among artificially-fed infants is far greater than among those fed on breast milk.

Dr. CHARLES G. KERLEY of New York said that true cases of milk idiosyncrasy were rare, and were often dependent upon faulty feeding at the beginning. He had found malt extracts excellent for improving the breast milk. The treatment of acute gastro-enteritis outlined by Dr. Shutt was to be commended.

Dr. J. LOVETT MORSE of Boston thought breast feeding should be continued so long as there was any milk in the breasts. He favored giving, in cases where the breast milk was scanty, some artificial food at the same feeding, because in this way one takes advantage of ferments found only in the mother's milk. The artificial supplemental feedings must be given on general principles and not on information gained from an analysis of the breast milk that the baby has been taking.

Dr. J. P. CROZER GRIFFITH of Philadelphia advised physicians to be guided in the feeding of infants by the old motto: "Be sure you're right, then go ahead." The mistake was too often made, by physicians as well as the laity, of jumping from one mixture to another without allowing sufficient time to determine whether or not the food is proper.

Dr. A. C. COTTON of Chicago deplored the fertility of our resources in infant feeding, because were it not for this we should be driven to the necessity of *making* the maternal adequate to the demands upon it. If every mother could be convinced that her babe would inevitably perish if it were not fed from the breast, what an increase in the percentage of cases of successful lactation there would be!

Dr. LEARNED of Massachusetts boldly advocated the use of whole milk from the very beginning, giving it in small quantities at intervals of three hours.

Dr. EDWARDS of California expressed the opinion that in the first few days of life much mischief was often done by giving certain foods, thus setting up an infection.

Dr. EDWIN ROSENTHAL of Philadelphia spoke of the difficulties encountered in the treatment of the poor children of the ignorant. In this class it was his rule in the summer season not to allow the mother to wean the child so long as there was any milk in the breast; this rule held good even when the mother was advanced in pregnancy as far as the eighth month. They are not allowed beer, because this makes the nursing infant colicky.

Dr. A. JACOBI of New York said that the chief information gained in the last ten or twenty years with regard to infant feeding, was that the cow's milk must be pure, fresh, and germ-free. The loss of weight observed during the first week of life could be largely avoided by feeding the infant principally on water until the milk secretion had been established.

Adenoids.—Dr. W. FREUDENTHAL of New York presented this paper. He said that the main symptom of acute adenoiditis was earache. Frequently the child would fall upon the ear. In his cases of acute adenoiditis there had always been fever, often to a considerable degree. Chronic hypertrophy of the pharyngeal tonsil, generally spoken of as "adenoids," was found under all climatic conditions. Catarrhal conditions, tuberculosis, and rheumatism were important etiological factors. The youngest child upon which he had operated for the removal of adenoids was seven months old, but ordinarily he did not care to do this operation upon children under two years of age. Slight hypertrophy did not call for removal. No amount of antisepsis would do good in such operations, and it often did harm. Syringing the nose before the operation was dangerous. He preferred to operate with the child flat upon the back, chloroform being given cautiously and not pushed to the extent of abolishing the cough reflex. It was not necessary to operate so radically as to remove even the normal adenoid tissue.

The Treatment of Acute Earache, Otitis Media, in Young Children.—Dr. GEORGE L. RICHARDS of Fall River, Mass., presented this paper. He said that he was fully persuaded that absorption of medicaments could take place through the tympanic membrane. When the inflammation had lasted for a considerable time, probably nothing but paracentesis would suffice, but in the early stages of many cases very great relief would follow the introduction into the external auditory canal of the gelatin and glycerin bougies recommended by the late Professor Joseph Gruber. The bougie should melt at or a little below the body temperature. Dr. Richards said that he had modified the formula of Woods, and, with the aid of his apothecary, had constructed a working formula. He had now used these ear bougies for four years and, as a rule, with very gratifying results. They were very useful in acute otitis media, and particularly in acute otitis externa, or furuncle of the external auditory canal. The bougie is kept in lycopodium, or is wrapped in tin foil, the latter being preferable. The powder should be washed off or the tin foil removed before use, and the bougie introduced into the ear after having been dipped in hot water. The ear is then stopped with [illegible] a [illegible] bottle placed over the ear. Both after [illegible] these [illegible] were [illegible] and then carried a distinctly [illegible]. Many [illegible] would [illegible] inflammation. The following was [illegible], boracic [illegible], salicylic acid, [illegible] grams. The [illegible] is [illegible]. [illegible] difficulty in securing a [illegible] of the [illegible] and [illegible], but they [illegible] due to the [illegible] dehydrated glycerin.

A Case of Angiosarcoma of the Kidney.—Dr. A. [illegible] of Chicago reported this case and presented gross and microscopical specimens.

The Unappreciated Causes of Some of the Anæmias of Childhood.—Dr. W. C. Hollopeter of Philadelphia read this paper. He asserted that the most important cause of anæmia in childhood, and the one least recognized, is dental decay. As a result of [illegible] the [illegible] alveolar abscesses discharge their contents into the mouth, and this in turn leads to gastro-intestinal catarrh and eventually to anæmia. It was of the utmost importance to prevent the acute catarrh from becoming chronic, and hence well nigh incurable. Another unrecognized factor in the production of anæmia in childhood was mouth breathing, and still another was eye strain.

Retropharyngeal Abscess in Infancy.—Dr. John Lovett Morse of Boston presented this paper. He said that the greatest number of retropharyngeal abscesses occur between the ages of four months and one year. These abscesses were almost always secondary to the cavities drained by the lymph nodes. Koplik had found streptococci in all his cases. Suppuration usually developed in five or six days, originating in a single node in the lateral wall. The symptoms of abscess were usually preceded by those of retropharyngeal adenitis. The character of the cry and of the respiration depended upon whether the abscess was situated high or low. In the acute cases the neck was extended and the head turned to one side. Swelling of the lymph nodes on the affected side of the jaw was very marked. Inspection of the throat was often not enough, hence in doubtful cases palpation should be employed. In untreated cases the termination was usually in death, the abscess rarely opening spontaneously. The pus may burrow in various directions and may open externally, even into the ear. The mortality in the cases treated by early incision was only about 5 per cent. As the drainage is fair and infection rarely occurs by the simpler method of internal incision, this should be preferred to the delicate and more dangerous external operation. A mouth gag should not be used, because its use sometimes leads to sudden death.

Dr. I. A. Abt of Chicago commented upon the much greater frequency of this affection in Europe.

Dr. C. G. Kerley reported a case in which the child suddenly ceased breathing upon the introduction of the finger and making downward pressure.

Dr. J. P. C. Griffith emphasized the frequency with which retropharyngeal abscess was overlooked, and this despite the peculiar position of the head and the spluttering respiration.

Dr. Frank X. Walls of Chicago suggested that it was not improbable that many children having retropharyngeal abscess were also victims of the lymphatic constitution, and that the reported sudden deaths might be explained in this way.

Report of a Case of Bulbar Paralysis.—Dr. A. C. Cotton of Chicago presented a further report on a case of this very rare disease of childhood.

Dr. W. S. Gottheil of New York and Dr. G. Wende of Buffalo gave a lantern demonstration of skin diseases.

Third Day—Thursday, June [illegible].

Synostosis of the Skull with Universal Calcification of the Arteries in a Boy, Three Years of Age.—Dr. David Riesman of Philadelphia reported this case, which had excited considerable interest because of the remarkable [illegible] and the [illegible] of [illegible] the [illegible] by any of the usual [illegible]. At the autopsy it was found that the temporal arteries were remarkably tortuous and the [illegible] and [illegible] of a [illegible]. The [illegible] were well marked up to within the [illegible] of the [illegible] and very [illegible]. The heart muscle was pale and the first portion of the aorta showed beginning [illegible]. The [illegible] of the skull were [illegible], and the brain bulged through the [illegible]. The [illegible] of the skull was [illegible] to six millimetres in thickness and [illegible]. The skull presented the same features at the base as at the [illegible]. The [illegible] of the lungs were found to be infiltrated with lime salts. The kidneys were the seat of both acute and chronic nephritis, and the calcification in the kidneys was more extensive than anything seen in adult life. There was no disease of the arteries of the heart. The question arose as to whether the synostosis was the cause or the consequence of the arrested brain development. The child had always been an idiot. Gross and microscopical specimens from this case were exhibited.

Spontaneous Hemorrhage in New-Born Children.—Dr. I. A. Abt of Chicago read this paper. He said that the hemorrhage might occur underneath the skin, into the serous cavities, or into the mucous membranes. A series of ten cases was reported, one of which was directly traceable to hereditary syphilis. The old hypothesis of Landau was that these cases were the result of embolism, but this theory was now no longer tenable. Congenital syphilis had long been held to be an important etiological factor, and the occurrence of these hemorrhages in premature and poorly nourished infants afforded some support to this view. Numerous micro-organisms had been found associated with these cases. Two of his own cases had presented plain evidence of pus infection, and in several others there was plainly a septic infection. In the opinion of the author it was not probable that a specific organism would ever be discovered, the hemorrhage being probably a symptom of several infections. No changes in the chemistry or morphology of the blood had been detected. In the obstetric clinics in this country the frequency of these cases of hemorrhage varied from one in 500 to one in 750 cases. In most instances the hemorrhage was a slow oozing, though exceptionally there was a profuse bleeding at intervals. In several instances ecchymotic spots were observed upon the soft palate. Hemorrhage from the umbilicus occurred in three cases, hemorrhage under the skin in six, from the nose in four, from the mouth in seven, from the stomach in two, from the vagina in two, from the bowel in five, from the ear in one case. The blood from the stomach was bright red, while that from the bowel was dark and sometimes clotted. The temperature varied considerably, being in one instance as high as 104° F., but the rule was for it to remain elevated throughout the entire course of the disease. In one case, however, it remained subnormal. Cyanosis had been a late manifestation in two cases. In a few icterus, and in one, convulsions and muscular twitchings were observed. It was worthy of note that the evacuations of the bowel were very offensive before the commencement of the hemorrhage. Apparently no internal remedy, not even suprarenal extract, exerted any influence upon the disease, and the local use of oxygen and of suprarenal was without permanent benefit. The external use of gelatin in one case had given some encouragement, and had led him to make some experiments in this direction. Three normal children were injected subcutaneously with a sterile two-per-cent.

gelatin solution. These injections were followed by a rapid pulse, chills, elevation of temperature and generally alarming symptoms. After this experience he had turned to experiments on rabbits. It was ascertained in this way that the blood removed twenty-four hours after the injection of the gelatin would coagulate in one-quarter of the time required for the blood taken before the injection. When large quantities of gelatin solution were injected under the skin of the abdomen of a rabbit they were uniformly fatal. The toxæmia produced by the injection of gelatin was not remarkable when one considered the source of gelatin and its uncertain composition, and it was probable that the toxic symptoms were dependent upon the presence of cadaveric poisons in the gelatin. The acidity of the gelatin was said to be due to the bleaching agents used in its manufacture, but this apparently exerted no influence on the results above detailed. The local use of gelatin, and its administration by the mouth, were warmly recommended by the author.

Dr. Holmes of Chicago said that one of the first persons to suggest the use of gelatin injections had seen fit to strongly condemn their intravenous administration because of the great tendency to produce clots. The speaker said that he had used it in this way in cases of post-partum hemorrhage without observing any special reaction.

Dr. A. Jacobi of New York said that years ago, when puerperal sepsis was comparatively common, he had frequently observed these hemorrhages in the newly born.

Dr. Frank X. Walls of Chicago thought he had seen a case in which the hemorrhage had been dependent upon malaria, and another case in which the underlying cause had been jaundice.

Sporadic Cretinism.—Dr. Rosa Engleman of Chicago reported a case of this kind, and exhibited a series of photographs together with a skiagraph of the child and another of a normal child of about the same size in order to show the departures from the normal bone development. She said that the first case of sporadic cretinism had been reported by Dr. A. Jacobi. The terms sporadic cretinism and myxœdematous disease should be restricted to the adult or neglected cases. It was certainly not an infrequent disease in infancy. Heredity seemed to be a factor in the adult form, but its influence in the infantile variety had not yet been determined. There was a growing belief as to the infectious nature of this disorder, but proof of this was still lacking. The parathyroids were known to develop in advance of the thyroid lobes, and to be concerned in the development of the nervous system. Anomalous innervation seemed to be the mainspring of the vicious circle. Obstinate constipation, abdominal distention, rudimentary detention, the dwarfism due to a symmetrical delay of ossification, and great prominence of the pisiform bone of the wrist, were marked features of sporadic cretinism. These children have a hoarse, peculiar cry and a sluggish gait. There seemed to be good reason for believing that there was an interrelation of the thymus, thyroid and pituitary glands. In her own case, thyroid feeding had not been begun until the age of seven years. As an experiment, the thyroid feeding was omitted for a time, and the administration of the pituitary gland substituted, with the result that the condition of the child retrograded during the continuance of the experiment.

Dr. Shelly of Kansas spoke of a case which had been treated by thyroid for the last seven years, it being now twelve years old. At first he had given about three grains three times a day, but this producing disagreeable symptoms he had given about half this dose, and latterly had given the thyroid only once a day.

Dr. A. Jacobi thought better results would be obtained in some cases by the use of thyroid combined with pituitary or thymus gland. In one case, although a good preparation of thyroid was used, it was necessary to give as much as 24 grains, three times a day for some time, and then to continue half this quantity.

Chlorosis.—Dr. C. F. Wahrer of Fort Madison, Ia., read this paper. He said that chlorosis could almost be predicted in girls who begin to menstruate early. Chlorosis was never due to menstrual troubles, nor did it ever give rise to tuberculosis, though the reverse was true. Anæmia, overwork, unsanitary surroundings and gastroptosis, usually brought on by tight lacing, were prominent etiological factors. In difficult cases the percentage of hæmoglobin should be estimated, as it was always markedly reduced—indeed, all of the symptoms were dependent upon this deficiency. One must differentiate it from nephritis by urinary analysis, both conditions often being associated with œdema. The author spoke emphatically against the erroneous popular notion that chlorosis is the cause of tuberculosis, and against the popular demand for the restoration of the suppressed menses. A common-sense hygienic treatment and the administration of iron were indicated.

Dr. Wells of Chicago said that it seemed to have been proved conclusively that the fundamental difficulty in chlorosis was a failure in the absorption of iron The physician should not neglect to examine stained specimens of the blood, using a preparation that would stain the granules of the nuclei of the white corpuscles. He made an earnest plea for routine and thorough blood examinations, and perseverance in a rational treatment. Often these cases of chlorosis would show little or no change under good treatment for six or seven weeks, and then would suddenly improve very noticeably. Rest in bed was often desirable, and all such patients should be cautioned against cold bathing or anything which might give them cold.

Dr. Darnall of Atlantic City said he had been impressed with the important part played by intestinal toxæmia in the production of chlorosis, and cited a case in illustration.

Recognition and Prompt Removal ef Post-Nasal Adenoids in Children.—Dr. Louis J. Lautenbach of Philadelphia read this paper. Touching upon its frequency, he said that he felt sure that he met with adenoids in fully 10 per cent. of all of the cases he saw in private practice, though he could not say that he met with this condition in children appearing to be in perfect health. The countenance, the mouth-breathing and the general lack of vitality usually pointed clearly to the nature of the trouble, and the diagnosis could be readily confirmed by exploration with the right index finger. These children were liable to the acute infections, and to such nervous disorders as enuresis, chorea and asthma. These children are apt to bolt their food because of the obstruction to breathing in the nasopharynx. Attention was called to the fact that the posterior and upper walls of the nasopharyngeal space were by no means always regularly and smoothly arched, and that sometimes vertical ridges were present on the posterior and upper pharyngeal wall He was of the opinion that if full and reliable statistics regarding the use of anæsthetics in adenoid operations were available there would be few who would have the hardihood to recommend general anæsthesia. He favored digital examination and operation with the finger-nail, natural or artificial, all at one operation. This method was quick, simple and thorough, and after it recurrences were rare. Albolene or mentholized oil should be used locally after this operation. There was usually little bleeding. The use of tonics and of other constitutional measures was important after operation.

Dr. W. C. Hollopeter of Philadelphia thought the majority of workers in this field preferred to operate in this manner and without anæsthesia.

Dr. S. W. Kelley of Cleveland also commended the method, and added the caution that as the artificial finger-nail sometimes slips off, it is prudent to secure it firmly by a turn of bandage around its lower ring and several turns about the operator's finger. This also prevented the child from biting the finger.

Dr. Shaw of Albany said that he was in favor of [illegible] general anesthesia, and [illegible] to the use of the [illegible], believing that more thorough work could be done with the curette.

Dermoid Tumors in Children.—Dr. E. W. [illegible] of Chicago reported in this paper a case of dermoid tumor of the pelvis in a boy of two years and a half, and one of dermoid of the ovary in a girl of eight years. The tumor of the pelvis contained bone, hair and sebaceous matter. The boy is now alive and well, seven years and a half after the operation. The other case was first seen about two years ago. The tumor had only been discovered about four months before, although having been thought to be due to attacks of intestinal obstruction. Recovery after the operation was uneventful.

Report of Three Cases of Sudden Death in Infants with Lymphatic Constitution.—Dr. Frank X. Walls of Chicago reported three cases. He expressed the belief that many cases of sudden death, supposed to be due to the mother's overlying the child, to negligence or [illegible] on the part of the nurse, or to a cat having "taken the child's breath," were in reality examples of so-called [illegible] sudden death occurring in infants of the lymphatic constitution. Gross pathological specimens were also presented, and they showed very clearly the enlargement of the thymus gland and the lymphoid hyperplasia at the base of the tongue, in the nasopharynx and in the intestines. Modern opinion, the speaker said, seemed to indicate that laryngismus stridulus was dependent upon cerebral and intracerebral irritation or hyperemia. There could be no doubt, from the histories of reported cases, that many sudden deaths in children were associated with enlargement of the thymus gland, and it was probable that in some instances the mechanical pressure of this gland was the cause. In many other cases, however, death was not due to asphyxia but to syncope, possibly from pressure on the nerves controlling the heart. The lymphatic constitution was very closely allied to, and, indeed, was probably part of rickets. It was claimed that deaths under chloroform occurred chiefly in those presenting this lymphatic constitution, and this might explain also the danger of chloroform in adenoid operations.

Dr. Shaw of Albany reported three cases of sudden death in children, in all of which the thymus had been distinctly enlarged, but careful search had failed to show any evidence of pressure on the trachea.

Officers Elected.—*President*, Dr. John C. Cook of Chicago; *Secretary*, Dr. Thomas S. Southworth of New York.

Choice of a Motor-Car for a Country Medical Man.—The Badminton Library has recently published a work on motor-cars by various writers. The section dealing with choice of motors is written by Mr. Harmsworth, and ultimately concerns medical men. The *Lancet*, alluding to Mr. Harmsworth's portion of the book, says: "Possibly the most important section to readers of the *Lancet* is that dealing with the 'Choice of a motor', and Mr. Harmsworth commences by saying that 'of the three or four hundred types and varieties now in existence many are of no practical use. Some are extremely complicated, not a few dangerous, and many more or less faulty in construction'—a premise to start from with which we entirely agree. Nothing could be more utterly useless to the country practitioner than a small under-powered car not capable of dealing with the hills in his neighborhood. Those that are too complicated may be ruled out of court at once, even if the buyer resides quite near the manufacturer. Amidst the 'dangerous' we should certainly be inclined to class for professional, daily and possibly rough use, all cars depending on tube ignition, though, perhaps, it may be passed as a dernier ressort in the event of the accumulator giving out. We would recommend the purchase of no car in which really heavy (relative) weights have to be carried and the 'drive' borne by balls such as are ordinarily used in bicycle construction; and, until vast improvements in their manufacture have been made, we cannot—and we speak from personal experience—advise any practitioner to purchase any car running on pneumatic tyres. The annoyance and delay of a 'puncture' are hardly to be regarded with equanimity. No matter how seldom it may occur, when it does occur it will upset the day's work and cause endless worry, confusion and expense, for it will probably mean hurried hiring, getting on as fast and as best one can, and telegraphing to the nearest motor depot or cycle agent to send out to repair the tyre. Furthermore, the use of pneumatic tires destroys the independence which is one of the charms of the motor. To be alone on a lonely road with a collapsed tire on a heavy car with night coming on, and perhaps in bad weather, is an experience which makes the [illegible] think a [illegible] not worth having. The frequency of punctures may be judged by the fact that in the 'reliability' trials at Glasgow last year it was decided that stops for punctured tires should not count, though the original intention was an 'absolute non-stop' trial and large allowance of time was made for every stop. This may be taken as an expression of the acknowledgment of the Automobile Club of Great Britain and Ireland that punctures are inevitable and 'do not count.' We may be thought to labor this point, but it is about the most important that the medical practitioner has to consider in the purchase of a car. Perhaps the 'New York' or some similar type may obviate the difficulty. The ordinary pneumatic tire with the ordinary outer cover is anathema. With reference to the question of petrol, electricity or steam, Mr. Harmsworth gives it as his opinion that 'a good petrol engine is infinitely the best for all-round work,' a view with which we are in accordance. The electric car can obviously only be of use in localities which have facilities for prompt re-charging, while our experience of steam cars is that, though very pleasant vehicles by daylight and while all goes well, they require too much watching and are rather too delicate for use after dark. Those that require a hot 'torch' as a preliminary to starting we can hardly recommend for the every-day work of medical practice, and those that are not entirely trustworthy in a high wind must be ruled out of court for the same reason, and, perhaps, also on the ground of safety."

The Martinique Volcano.—Some of the phenomena attending the destruction of St. Pierre have been difficult to explain, especially the sheet of flame that seems to have accompanied or closely followed the violent explosion of gas. Professor Verrill of Yale states his view to be that the heat is sufficient to cause the dissociation of hydrogen and oxygen from water coming suddenly into contact with the lava in the crater, and that in the case of sea water, chlorine would be dissociated from sodium. These gases suddenly ejected with great violence and exploding in the air above the crater would produce the effects manifested on so great a scale at Martinique. The people were killed by the sudden explosion of a vast volume of hydrogen and oxygen, and this accounts for the sudden burning of flesh and clothes, as well as of buildings and of vessels in the roadstead. The chlorine combining with some of the hydrogen would produce hydrochloric acid, which is poisonous and suffocating, and would quickly kill all those not destroyed by the first explosion.—*New York Sun.*

German Government Condemns the Use of Boric Acid.—The *North German Gazette*, in a semi-officially inspired article, says the German Government now speaks the last word regarding the use of boric acids for the preservation of meat. After giving an exhaustive description of the technical investigation and experiments on this subject the paper says:

"The sanitary department and the medical authorities are unanimously agreed that the use of boric preparatives to the extent necessary for the preservation of meat should not be permitted."

Book Reviews.

Nursing, General, Medical and Surgical, with Appendix on Sick-room Cookery. By Wilfred J. Hadley, M.D., Physician and Pathologist, and Lecturer to the Nurses, London Hospital. 326 pages. Philadelphia: P. Blakiston's Son & Co., 1902.

This handy little volume is written in a clear and concise style, and the teaching is sound and practical, but we cannot help thinking that it is unnecessary and undesirable to encourage even the modern trained nurse to try and grasp the whole domain of medicine and surgery. The author has succeeded admirably in compressing a vast amount of information into a form available for ready reference, but such highly concentrated mental pabulum is difficult of assimilation, and, in our opinion, the nurse needs no extended instruction in diagnosis, prognosis and treatment.

Manual of Childbed Nursing, with Notes on Infant Feeding. By Charles Jewett, A.M., M.D., Sc.D., Professor of Obstetrics and Diseases of Women in the Long Island College Hospital. Fifth edition, revised and enlarged. Pp. 84. New York: E. B. Treat & Co., 1902.

This little book is especially commendable from its great clearness and preciseness of expression. It would seem to be impossible even for a layman of less than average intelligence to misunderstand any of its directions. The concise, dogmatic statements are calculated to impress upon the reader the essential facts which need to be kept in mind at the bedside.

One can readily understand the popularity of this manual and will desire to see it in the hands of every pregnant woman, as well as in those of the obstetric nurse.

The chapter on the care of the child is quite comprehensive. Artificial feeding, a subject which has assumed such prominence in recent years, is carefully described. The objection may be raised that formulæ are multiplied, to the possible confession of the lay reader. It would be unfair to criticise such an elementary work from a theoretical standpoint. We could wish, however, that in the section on hand-disinfection some reference had been made to alcohol, and that the lime and soda method had been given the preference over the permanganate and oxalic acid, which has been generally abandoned by surgeons.

Etudes Anatomiques Sur Les Grossesses Tubaires. Por Le Dr. A. Connelaire, Ancient Interne des Hôpitaux, Chef de Clinique Obstitricale à la Faculté de Médicine de Paris. Pp. 160. Paris: G. Steinheil, Editeur, 1901.

This excellent monograph is enriched by twenty-one beautiful plates, which, although not of equal excellence, serve to illustrate the text in the fullest manner.

Chapter I deals with classification, and includes the different varieties of tubal pregnancy during the first three months of its development.

Chapter II is devoted to anatomy, a considerable portion of it dealing with the changes of the tubal mucous membrane under the influence of normal pregnancy, which the author regards as only slight as compared with those in tubal gestation.

In Chapter III the anatomy of the impregnated ovum is studied, and in Chapter IV the development of the placenta. In the concluding chapter (VI) there is a brief consideration of the causes and anatomy of rupture. Reports of fifteen cases are appended.

Mental Growth and Control. By Nathan Oppenheim, M.D. New York: The Macmillan Co.

This small volume is one of the "Personal Problem Series," published by the Macmillan Co., books of counsel, whose object it is to teach young men and women how best to shape their ideals and their lives. The subjects treated on in this volume are: The growth of character, the mind as a machine, the power of attention, what association means, the uses of instinct, memory and its development, the bonds of habit, hypnotism and suggestion, imagination, education of the emotions, reasoning and will. It will be seen from this enumeration that the writer is given plenty of latitude. Whether or not he has succeeded satisfactorily will depend upon the reader's point of view.

The book is evidently designed to help very young people and as such may be said to have attained its end. The subjects are treated in a commonplace manner, and after reading a number of the chapters one is left with a feeling of disappointment that such subjects were not thought worthy of better treatment. There is nothing in the book to enlighten an adult of average intelligence and experience. The style of the writer, one may truthfully say, is somewhat condescending. The author seems to have been convinced that he must write down to the level of his readers.

A Manual of Clinical Diagnosis by Means of Microscopical and Chemical Methods, for Students, Hospital Physicians and Practitioners. By Charles E. Simon, M.D.,, of Baltimore, Fourth edition, thoroughly revised. Illustrated with 130 engravings and 19 plates in colors. Philadelphia and New York: Lea Brothers & Co., 1902.

The mere fact that the third edition of this work was exhausted in but little over a year's time vouches for its practical usefulness. In this issue we find a worthy successor to the preceding editions, the author having incorporated into his work all the recent advances in laboratory methods which he deemed of value. The lack of references to the literature in the older editions has been corrected, and we find a very satisfactory though concise bibliography in the present volume, such as would be helpful to those seeking more exhaustive information on particular subjects. We note with pleasure the endorsement of Jenner's stain for routine blood-work, and the addition of a few engravings and a colored plate to the already valuable and excellent set of illustrations.

A System of Physiologic Therapeutics. A Practical Exposition of the Methods Other than Drug-Giving Useful in the Prevention of Disease and in the Treatment of the Sick. Edited by Solomon Solis Cohen, M.D., Professor of Medicine and Therapeutics in the Philadelphia Polyclinic; Lecturer on Clinical Medicine at Jefferson Medical College. Vol. VI., Dietotherapy and Food in Health and Disease. By Nathan S. Davis, Jr., A.M., M.D., Professor of the Principles and Practice of Medicine in Northwestern University Medical School. Philadelphia: P. Blackiston's Son & Co., 1902.

In practical treatment of the subject, from a truly American standpoint, this volume equals, if it does not excel, all the preceding ones. There is a genuine Western directness in the pithy style of the author, which will satisfy the active practitioner by its conciseness and thoroughness. Complete diet lists for the healthy are given from the most recent investigations of American authorities. An interesting table is furnished from abstracts of the reports of the U. S. Agricultural Department, showing "American and European Dietary Standards." Here we find an instructive comparison of the nutritive value of foods consumed by all classes, including negroes and Mexicans. The chapter on milk deals with every phase of this and of all other articles of diet. All foods are discussed fully. The author is, like his father, an authority on alcohol. He insists justly that "Alcohol is unnecessary in health; that alcoholic beverages do so much harm that their utility has been denied under any circumstances." A bedside observation of forty years has convinced this reviewer that the author states correctly the stimulating properties of alcohol to the failing heart to be ephemeral, and that there are other medicaments capable of producing similar results without the depression incident to the frequent repetition of alcohol. The chapter on infant feeding is clear and instructive. Part II. is devoted to "Diet in disease." After some general considerations the diet adapted to the most common diseases is separately considered. Among these emaciation and obesity properly receive attention.

Absence of pedantry and limitation of theoretic discussion are striking characteristics of this book. The busy practitioner will appreciate these qualities.

The American Year Book of Medicine and Surgerx. A yearly digest of scientific progress and authoritative opinion in all branches of medicine and surgery, etc. Collected and arranged with critical editorial comments by J. M. Baldy, M.D.; Charles H. Burnett, M.D.; J. Chalmers Da Costa, M.D.; W. A. N. Dorland, M.D., J. H. Gibbon, M.D.; V. P. Gibney, M.D.; C. A. Hamann, M.D.; H. F. Hansell, M.D.; Barton C. Hirst, M.D.; E. F. Ingals, M.D.; Henry G. Ohls, M.D.; Wendell Reber, M.D., and J. H. Waterman, M.D. Under the editorial charge of Geo. M. Gould, M.D. Surgery. Philadelphia and London: W. B. Saunders & Co., 1902.

This painstaking and comprehensive epitome of surgical literature and progress is again before us. Its editors have done an enormous amount of work in sifting and collating material, and they deserve our thanks. Articles for criticism have been judiciously selected, and the volume, therefore, possesses considerable value as a work of reference, for the busy man who finds it impossible to give time to a multitude of medical journals. The book is offered in attractive form.

Medical Items.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, New York City, for the week ending June 14, 1902:

	Cases	Deaths
Measles	[illegible]	[illegible]
Diphtheria and croup	[illegible]	[illegible]
Scarlet fever	[illegible]	[illegible]
Smallpox	[illegible]	[illegible]
Varicella	[illegible]	
Tuberculosis	[illegible]	[illegible]
Typhoid fever	[illegible]	[illegible]
Cerebro-spinal meningitis		[illegible]

Overcrowding in Chicago.—As predicted by Jacob Riis the New York social reformer Chicago is confronted with a serious crowding of its population, which will give rise to conditions similar to those in New York. According to the report of the Special Parks Commission of the City Council there are large sections of the city in which the people "have no room to live," and in which the conditions of morality and health are such as to demand immediate steps looking to their betterment. The most thickly congested districts of the city are on the west side, where a large part of the foreign population of the city has settled. In ten blocks in one of these sections the commission found 2,600 people living in alleys. In the same district 3,125 people are living in basements, and the mortality record runs up to thirty-seven in a thousand, nearly three times the average of the city. Of the ninth ward, or the ghetto, which is the most populous school district in Chicago, if not in the world, the report says: "There are 14,300 boys and girls living in about one square mile of territory who have no park or playground within ordinary walking distance. The people suffer intensely from overcrowding, almost every available foot of ground being occupied with tenements. One block has a population of one thousand persons. Cellars, basements, outhouses, all are used for living purposes." The report concludes by saying that persons living in such conditions can never acquire that standard of citizenship which this city must secure for all its law-abiding and law-making people.

As a means of decreasing the frightful death rate in these sections and relieving the congested conditions the commission has submitted nine sites for small parks, of which five or six will be immediately selected by the West Park Board. In addition to the West Side, small parks are to be established on the North and South sides, but as the West Park Commissioners have the money available for that purpose, those in that section of the city will be established first. The Park Commissioners have $1,000,000, raised by special bond issue, to spend for the parks, and the authority to levy a one mill tax for their improvement and maintenance. One of the parks will probably be named for Miss Jane Addams of Hull House, who has long been identified with the movement for the betterment of the social conditions in the crowded sections of Chicago.—*New York Tribune.*

Count Tolstoy.—A St. Petersburg correspondent reports that the restoration of Count Tolstoy to health is a very slow process. The inflammation of the left lung is not yet healed, and gives him such pain as to deprive him of the sleep he sorely needs. For a considerable time Count Tolstoy felt so much stronger that he could stand continuous reading and working, and answered much of his correspondence himself. During this period he composed a long preface for the new edition of his earlier works that is to appear. After a slight setback in the middle of April the count had to give up all work and again take to his bed. At present he feels again somewhat better, and, contrary to the strictest directions of his physicians, has left his bed and begun his literary work again. Since the spring in the Crimea has been very raw and cold, his friends and attendants have a justifiable fear of his again catching cold, as the Count insists on having fresh air continually.

Health Reports.—The following cases of smallpox, yellow fever, cholera, and plague have been reported to the Surgeon-General, U. S. Marine Hospital Service, during the week ended June 14, 1902:

SMALLPOX—UNITED STATES		Cases	Deaths

THE DIFFERENTIAL DIAGNOSIS OF TYPHOID AND MALARIAL FEVERS, WITH ESPECIAL REFERENCE TO THE OCCURRENCE OF BOTH DISEASES IN THE SAME PATIENT: WITH REPORT OF CASES.*

BY ISAAC IVAN LEMANN, M.D.,
NEW ORLEANS.

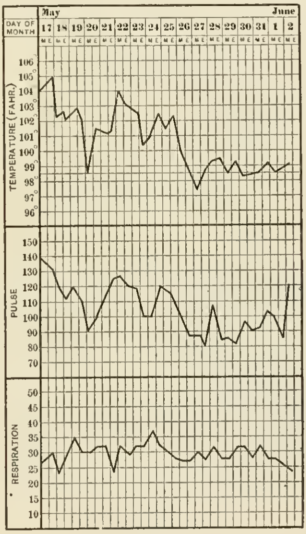
IN this section of the country there are two chief forms of continued fevers prevailing, namely, typhoid and malaria. The diagnosis of the one from the other is of the utmost importance, for their treatment is radically different, and the life of the patient often, his rapid cure always, depends on the prompt institution of the proper line of treatment. Yet, in many instances, the diagnosis is made with the greatest difficulty and only after every diagnostic measure has been employed.

It is not the purpose of this paper to consider in detail the relative value, from a diagnostic standpoint, of the various symptoms of these diseases and of the data derived from laboratory methods, but rather to point out wherein the difficulty of diagnosis lies, and to show the necessity of proceeding with caution in cases of doubtful character. Secondly, its purpose is to consider cases where the two infections—malaria and typhoid—occur in the same patient.

A diagnosis cannot be made by machine; you cannot put in two or three or a group of what you may consider classical symptoms at one end of the mill and take out a diagnosis at the other. In a discussion of typhoid fever, Dr. William Osler states (*New York Medical Journal*, November 4, 1899) that there are no two or three symptoms characteristic of the disease. The hard-worked practitioners of country districts must rely in great measure on experience and common sense.

How closely malaria may simulate typhoid, and how it may exhibit in marked degree nearly every one of the classical symptoms that are supposed to be characteristic of typhoid and to set it off as a disease apart, is well illustrated by the following case:

CASE I.—Lillie L., twenty years old, white, single. Admitted to Ward 51, Charity Hospital, May 17, 1899. Said she had been feeling ill since Sunday, May 8, but had not gone to bed until the Friday following. Bowels were normal, one stool daily. She had had frontal headache all along, and on the morning of admission had had epistaxis. On admission—face expressionless and languid. Tongue pointed, very red on edges and coated in middle. Temperature, 105°; pulse, 140; respiration, 28. Examination showed heart and lungs normal. Liver normal. Spleen not enlarged nor tender. No tympanites. Some gurgling in right iliac fossa and a few rose-colored spots on the chest and abdomen. Patient six months pregnant. A few hours after admission epistaxis returned, and was so severe that the anterior nares had to be packed with iodoform gauze, soaked in 10 per cent. antipyrin solution.



CASE I.

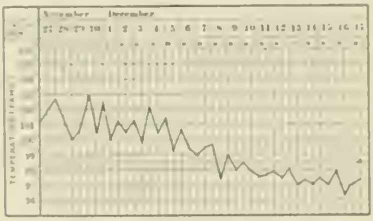
From the patient's typical history, the tongue, the severe epistaxis, the rose-colored spots, the depressed condition not often seen in malaria, from the iliac gurgling, a diagnosis of typhoid fever was made, and the treatment proceeded with on this assumption. An intestinal antiseptic—salol at first and guaiacol carbonate in essence of pepsin afterward—was administered, and hydrotherapy, in the form principally of baths (from 80° to 90°) for a temperature of 102.5°, was used for control of temperature. The temperature the first day went as high as 105.6°, but after that ranged from 100° to 103° until May 20, when it fell to normal of its own accord. However, it immediately rose again and ran the same course. The pulse was rather irregular when the temperature had fallen, and the patient's general condition seemed so depressed and serious that the fall of the temperature did not rouse suspicions of the true state of affairs as did the blood examinations. Blood analysis of May 18, 19 and 20 each time showed Widal's reaction negative, but plasmodia malariæ present. The pregnancy caused some timidity in the free use of quinine at first and cinchonidia sulphate was used in 2½-grain doses, in conjunction with guaiacol carbonate 2½ grains and salol 1 grain, beginning May 22. May 23, quinine sulphate 2½ grains was added to the powder. Hydrotherapy was continued. The temperature still continuing 102° to 103°, all timidity was cast aside and full doses of quinine were instituted on May 25 (five grains every four hours). The effect was immediate. Temperature reached normal within thirty-six hours and remained so. Convalescence was without feature of interest. This case pointed a moral in the matter of snap-shot diagnosis. Here the original strong points in the diagnosis were afterwards backed up by the reappearance of the epistaxis, the appearance of albumin, ½ per cent., and granular casts in the urine, the development of a splenitis as evidenced by a moderate enlargement and tenderness, and finally by the occurrence of a hemorrhage, induced probably by the hydrotherapeutic measures. And yet it was all knocked into a cocked hat by the spontaneous fall of the temperature and the blood examination. The chart would indicate that the attack was nothing more than an intermittent malaria of the quartan type.

---

*Read before the Orleans Parish Medical Society, March 8, 1902.

Still it were better, if a mistake is to be made at all, to err on the safe side and to treat an attack of this sort as presumably typhoid and to meet all hyperpyrexia with measures not calculated to depress the patient. Professor Osler, in the article already quoted, says: "Learn to suspect typhoid and not malaria in every case of fever of six or seven days' duration, particularly if it resists the action of quinine. For too long you have employed the Anglo-Saxon method of procedure and in a given case have assumed innocence of anything so serious as typhoid until in the onset of some serious symptom the guilt was only too evident. It is high time now that you adopt the Gallic usage and regard every case of continued fever as guilty, that is, as typhoid, until the contrary be clearly demonstrated." The soundness of this advice may be shown by the following:

Case II.—Luke E., twenty years old, white, single, strong, healthy-looking young man, about five feet ten inches, and weighing about 170 pounds. Admitted to ward 17 on morning of November 27, 1899. Said he had been sick about four days, during which time he had chilly sensations, general malaise, lassitude and frontal headache. Bowels were costive. Patient had been drinking spring and cistern water. Had never had any attacks of continued fever, but had chills and fever during the summer of 1898. On admission temperature was 103⅗° F. Pulse, 70; respiration, 20 to 25. Physical examination was negative. All thoracic organs normal. Liver and spleen normal absolutely. No abdominal tenderness, and no eruption. Tongue broad, red on edges, brown coated, no indentation. Patient was put to bed, on liquid diet, and was given phenacetin, 2½ grains, caffein citrat, 1 grain, and Epsom salts ℥ss. Quinine 5 grains was administered every four hours. November 28, morning, temperature, 102⅘°. Bowels had not moved. Salts repeated. Quinine 5 grains every three hours. Afternoon, temperature was 100⅗°. Blood examination: no plasmodia, Widal negative. The quinine had apparently had some effect on temperature and the absence of plasmodia was attributed to its use. November 29, quinine continued. Morning temperature, 101°. Afternoon temperature, 102⅘° (this in spite of quinine). Bowels moved once. November 30, quinine continued. Morning temperature, 101°; afternoon temperature, 103°. Widal's reaction negative. Bowels had not moved for thirty-six hours. Calomel and soda, each ¼ grain, were given, followed by Epsom salts. An enema had to be given finally to move bowels. December 1, morning temperature 102⅘°. Patient has had quinine 5 grains every three hours for over seventy-two hours without influencing temperature; hence it was discontinued. Patient complained for the first time of sore throat. Gargle prescribed of salol gr. x, menthol gr. ⅓, alcohol ʒiv, ℥i to a cupful of water. Afternoon temperature, 103⅗°. December 2, morning temperature, 101⅘°; afternoon temperature, 103⅗°. About the same as when the patient was taking quinine. Blood examination: no plasmodia, twenty-four hours after cessation of quinine. Widal negative. December 3, temperature 101 to 103°. Bowels very costive. Throat better. No plasmodia. December 5, temperature 101 to 102⅗°. Widal positive. December 5 to 17, temperature gradually defervesced in a typically typhoid manner. Widal's reaction was positive again on December 6, and on December 9 it was positive at a dilution of 1:100. It will be noticed that the bowels were exceedingly costive throughout the attack. There was absolutely no depression and not a single typhoid symptom. There was no time at which patient did not feel perfectly able to get up had he been allowed. As it was, he amused himself reading the newspapers and studying the bed chart. Still here was a temperature that persisted after every probable cause other than typhoid had been eliminated: malaria (both by the use of quinine and by blood analysis), appendicitis, autoinfection from constipation, any local suppuration or inflammation—all these had been eliminated. Here, too, we had the Widal test positive at the great dilution of 1–100, and this after it had been negative for several examinations. This last fact corroborates the patient's statement that he never had typhoid previously, for if he had had it before the test would have been positive at the beginning as well as at or near the end of the attack.

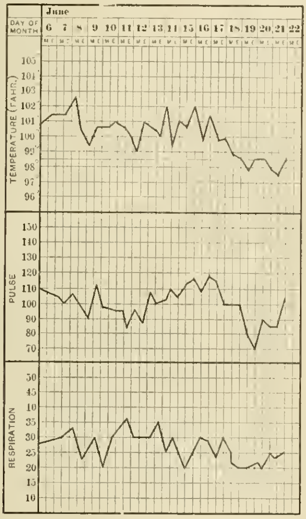


Case 2.

In view of these strong proofs, it was easy to arrive at the conclusion that this man had an atypical case of typhoid—one that might be classed with the ambulatory cases. But the conclusion was reached only when the patient was nearly convalescent, the case having been all along looked upon as being suspicious of typhoid and been treated accordingly. Armed with the determination to treat with suspicion all doubtful cases of continued fever, we are protected against doing our patients much unintentional harm that would fall to their lot did we not follow Professor Osler's rule.

But the problem is further complicated by the fact that both typhoid fever and malaria sometimes occur in the same patient at the same time. Such cases require the same cautious handling and the same close observation until their true nature is disclosed, and their rapid cure, as the histories to be cited will show, is dependent upon the recognition of the double infection. In this class the treatment of each individual case is more or less a rule unto itself. It is true these cases are comparatively rare. Says Thayer: "Malarial fever is occasionally complicated with typhoid fever. A person suffering with a chronic or relatively latent malarial infection may develop typhoid fever, or at some time during the course of the convalescence from typhoid fever a relapse from a preceding material attack may occur; in some instances, the two infections may be coincident in time. A fresh malarial infection during typhoid is rare. It is unusual for well-marked symptoms of the two diseases to be present at the same time. More commonly the malarial paroxysms appear during convalescence from typhoid fever. Even these instances are not common." The following cases seem to illustrate the coincident infection of the same patient with both diseases:

Case III.—Mary C., twenty-seven years old, admitted to ward 51, June 26, 1899. She had had fever continuously since May 28. Illness was sudden in onset. Bowels were normal. On admission the clinical aspect was that of malaria. Tongue was thick and indented. No depression. No abdominal symptoms, beyond a diarrhœa that developed within a day or two. Spleen slightly enlarged. Temperature 101.8° F; pulse, 104; respirations, 32. Quinine, 5 grains every four hours, was begun on the morning of June 7 with acid hydrobromic dilute ʒ ss every six hours. Fowler's sol. gtts. vii t.i.d. was also given. June 7, A.M., temperature, 101°; pulse, 100; respiration, 32. June 7, P.M., temperature, 103°; pulse, 104; respiration, 34. June 8, A.M., temperature, 100°; pulse, 96; respiration 32.



Case 3.

Temperature fell to normal about 2 P.M., on the 8th, but rose to 100° at 4.30 P.M. Quinine was kept up until June 12, during which time bowels were moving five or six times during twenty-four hours. Temperature ranged usually circa 101°, but touched normal once more on the 10th—only to immediately rise again. This falling of the temperature twice to normal tended to confirm the diagnosis of malaria, while the blood analysis also backed it up, for, on June 7, plasmodia were found and Widal's reaction was negative. On June 11 patient developed a considerable amount of tympanites--rather an unusual symptom in malaria. June 12 the blood report was: No plasmodia. Widal's test positive—at the usual dilution (1-50). Since the 10th the temperature was showing no tendency whatever to yield to the continued use of quinine. In simple malarial cases of the acute remittent type the temperature, once having yielded to quinine, will remain normal if the quinine be continued. Physical examination of the patient on June 11 revealed a slight bronchitis and a certain enlargement of the spleen. There was also some gurgling and tenderness in the right iliac fossa, which had hitherto not been present. Further blood examinations showed: June 13, Widal positive, 1 to 80. No plasmodia. June 14, Widal positive, 1 to 100, bacilli immotile, but not clumped. June 15, Widal positive, 1 to 100. June 12, the quinine and Fowler's solution were discontinued. Patient had been taking strychnine sulphate gr. 1-30 since the day before. A powder of Bismuth B. Naphtol grs. v, salol and guaiacol āā grs. 2½ every four hours was ordered.

Under this the tympanites decreased and disappeared and the diarrhœa was corrected. Hydrotherapy was used to combat pyrexia (sponging and ice-water enema alternately for 102.5; ice cap continuously for 100°). Patient nourished well throughout and was not depressed. June 13-14: The temperature continued to rise, the maximum being 102.8°. Antipyretic measures had to be used but four times. June 15 and 16, maximum temperature 103°. June 16 to 18, temperature fell gradually, reaching normal morning of June 18. At this time every symptom had subsided and patient looked as if she had never been sick.

How are we to interpret the facts in this case. Did she have remittent malaria alone? Did she have typhoid alone? Or did she have both? I think she had both. In the first place, let us notice that the course of the disease was a most anomalous one for typhoid, and if the patient had typhoid at all it was of an abortive type. Still I believe we are justified in arriving at the diagnosis of aborted typhoid, because of the striking typhoid symptoms presented, and more especially of the Widal's reaction, which has proved of the utmost value in the diagnosis of fevers in this hospital. It may be said that the presence of the reaction might be due to a previous attack of typhoid at a distant date. But this could not be, for the reaction was not obtained when the patient first entered the ward, and if she had had a previous attack of typhoid, the reaction would have been positive on the first examination, as well as on the second and third, etc. Moreover, the reaction was later obtained at the great dilution of 1 part of blood serum to 100 parts of typhoid culture, and after twenty minutes only. Such a striking reaction is not usually obtained in a patient not actually suffering from the disease and merely immunized by a previous attack. Moreover, we have the negative evidence that the patient gave no history of a previous typhoid fever.

Did she have malaria also? The finding of the plasmodia would so indicate, for they are not found save in the blood of persons suffering from malaria in some form. The patient did not have the anæmic and cachectic appearance of one suffering from chronic malarial toxæmia, and she gave no history of having been sick for a long period. The disease was sudden in its onset, resembling in this malaria rather than typhoid. The influence of quinine was decided, for the plasmodia disappeared and the temperature fell to normal. I conclude, therefore, that this woman was suffering from an acute malarial infection. The temperature rose again when the typhoid element asserted itself and resisted the antipyretic action of the quinine; but the typhoid, too, in its turn, was aborted by the use of intestinal antiseptics and astringents.

Case IV.—Miss R., a probationer in the Training School for Nurses, had been in the hospital but three weeks when she began to complain. During these weeks she was assigned to a service in which there were a half dozen typhoid cases. Her previous history follows. She had been living in Virginia and came direct from there. In the summer of 1898 she had an attack of continued fever, which lasted several weeks. However, she was not confined to bed during the whole of this period, but was able to creep down stairs nearly every day. She could hardly have had typhoid fever at this time; it was more probably an attack of malaria.

For several days she complained of headache and malaise, but nevertheless continued at her work. Her temperature, when first taken, was about 102°. She was kept in the nurses' apartments for two days, during which time her temperature ranged 100 to 103°. July 20, 1899, she was admitted to ward 52, with temperature 103.5°, pulse, 100; respiration 27. She was not depressed. Bowels were moving two or three times in twenty-four hours. No abdominal tenderness, but some few spots on abdomen. Heart and lungs normal. Spleen and liver normal. She was given salol, 5 grs. every four hours, and was sponged for temperature of 103°.

July 21 to 23, temperature ranged 100.5° to 101° in the morning, to 103° in the evening. Patient had to be sponged about 4 twice in twenty-four hours. Bowels costive. Blood analysis shows no plasmodia. Widal negative (July 21). On July 21 the patient was given quinine sulphate, 5 gr. every six hours for twenty-four hours, but this was discontinued next day, as the diagnosis of typhoid was thought positive by those then treating her.

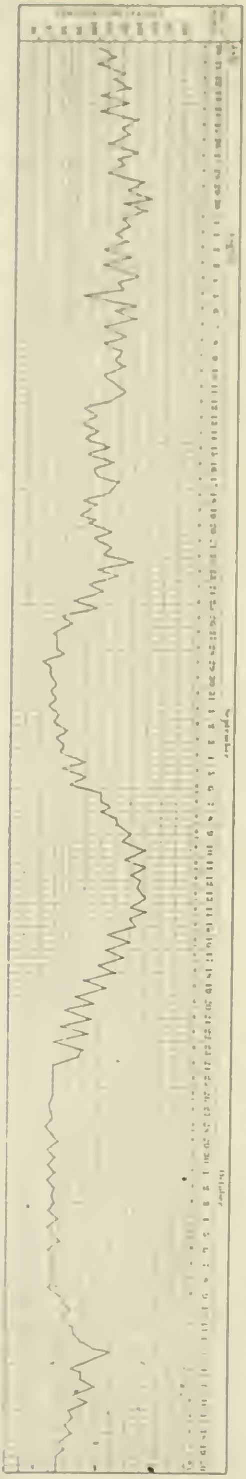
July 23, the temperature ran a little higher, reaching each evening a point above that of the preceding evening. On July 26 it was 104°. It remitted to 102° in the morning and patient had to be sponged four times in twenty-four hours. Bowels were very costive and had to be opened by enemata or salines. Temperature ran a little lower on the 27th. Blood examination: July 25, Widal negative. July 31, no plasmodia, Widal positive. There had been no depression and patient was well nourished. Pulse 80 to 95, full and of good quality, respirations, 20 to 30. Patient took strychnine sulphate gr. 1/30 and salol grs. v. every four hours.

August 5, the temperature, which was 104° in the evening of the 4th, remitted to 99.8° on the morning of the 5th, whereas its usual remission was only to 101.5° to 102°. Blood analysis: Widal negative. August 6 to 11, temperature rose to circa 103° in P.M., and remitted to 101°. There were no more sudden falls. Bowels are slightly loose, one to four stools in twenty-four hours. August 7, clots of blood in stool. August 8, abdomen slightly distended. August 11, malarial infection suspected in spite of blood analyses, so salol is discontinued and quinine hydrobromate grs. v. every four hours was given in conjunction with the strychnine. The next day (morning of 12th) the temperature fell to 99½°. Note that this was just one week since the last marked remission. The quinine was continued through the week, and showed its influence in so far that the temperature ranged a whole degree lower than it did the week previous, never going above 102°. Bowels continued costive. Blood examination, Widal negative. No plasmodia (August 15). On the morning of the 19th patient was given 10 grs. of the quinine at 6 and 10 A.M., instead of 5 grs. The temperature reached 98° that morning, but rose to 101.5° in the evening. Plasmodia were found in the blood for the first time—and this in spite of the long-continued and large doses of quinine. The quinine was now discontinued, and its withdrawal had the effect that from August 20 to 28 the temperature rose again to 103° and ran a degree higher than it had the week during which the quinine was administered. Blood analysis during the week showed: August 20, no plasmodia, Widal negative. August 23, no plasmodia. August 28, plasmodia found.

On August 25 and 26 the quinine was given 5 grains every three hours in afternoon of 25th, and 15 grains at 5 A.M. and 8 A.M. of the 26th, and again every three hours in afternoon of the 26th. Temperature reached normal on the 26th, just a week from last remission and two weeks from the first remission. Temperature now remained normal until September 4, during which time she was taking a tonic of 5 grains of quinine and 5 drops of Fowler's solution, three times daily. Light diet was permitted August 31. Patient had a good appetite and declared she felt fine. On September 4 she took a very short walk (one block) without permission. That night the temperature was 100.5° instead of 98.8°, pulse, 100 instead of 80, respiration, 32 instead of 22. And now began a second attack, which ran a typical typhoid curve with regard to the temperature and which resisted quinine in the heaviest doses.

September 4 to 10, temperature mounted steadily higher reaching 104° the afternoon of the 10th. Quinine hydrobromate 5 grains every three hours and Fowler's solution 5 drops t. i. d. were given, but without influencing the temperature whatever. On September 9, which was the usual seventh day, the quinine was massed in 15 gr. doses, but this also failed. Widal's reaction on this day was negative. Patient had to be sponged four to six times in twenty-four hours. Spleen was large and tender.

September 10, quinine discontinued. Fowler's



CASE

solution 5 drops, and Batley's cinchona 10 drops every four hours tried, but discontinued at once. A capsule of phenacetin 2½ grains, calomel $\frac{1}{12}$ grain, pulv. ipecac ¼ grain every four hours had no effect on temperature, and was discontinued after twenty-four hours. September 10 to 15, temperature ranged around 104° continuously and did not remit. Patient had to be tubbed every three hours. She stood tubbing splendidly and nourished well, but was considerably depressed. Strychnine gr. 1-30, Tr. digitalis mx. were administered hypodermatically every four hours. Bowels moved two or three times every twenty-four hours, stools being loose occasionally, but generally constipated. Pulse, 120 to 130. By the 12th the tenderness over spleen had disappeared. Blood examinations showed: September 12, no plasmodia, Widal negative. September 15, plasmodia present, Widal negative. September 16, no plasmodia, Widal positive. September 22, *plasmodia present and Widal positive.* On September 15 the salol was replaced by Ac. nitrohydrochloric dil xv every four hours. On September 16 there occurred the first distinct remission, and from this day there was a gradual descent until September 28, when the temperature reached normal. Patient now entered on convalescence for the second time. On October 5 she was given a tonic pill of quinine, iron, arsenic and strychnine. Temperature remained normal until October 10, when it began gradually to rise again. Meanwhile she had been feeling well, except for some slight abdominal pain, due to constipation and relieved by drachm doses of soda phosphate night and morning. Temperature reached 102.3° the afternoon of October 13. Twenty-five grains of quinine were given, each morning, in 10 and 5-grain doses, at one hour intervals for two successive mornings. Temperature immediately fell and ranged 100 to 101°. After October 26 temperature never went above 90°.

The study of this case is interesting for several reasons. An every 2-hour chart of the first attack shows beautifully a marked periodicity of the temperature, and a glance at the morning and evening chart will reveal a like periodicity in the run of temperature during the week. There was a well-marked tendency, to which attention has already been called, for the temperature to fall on the morning of the seventh day and to immediately rise again and run the same course. Periodicity is the characteristic of malaria, and some authorities describe as the typical remittent malarial fever prevalent in the Southern States, a fever which exhibits invariably the temperature curve shown in the first attack of this patient. According to these authorities, the temperature in remittent malarial fever shows at the end of each week a well-marked disposition to defervesce abruptly at the end of each week but will, unless quinine be administered in heavy doses on the seventh day, immediately rise and run another week without intermisson.

But if the first attack, with its characteristic periodicity and unmistakable yielding to quinine, has the malarial element more prominently in the foreground and the typhoid in the background, the second attack, with its great depression, acute splenitis, and resistance to quinine, is typically typhoid and has little or none of the malarial in it.

It is impossible to pass over without comment the queer antics evident in the results of the blood analyses. That we should get at first neither Widal nor plasmodia, then Widal, then neither for a stretch, then plasmodia alone, again neither for quite a long a time, and finally both together, is strange. The technique of blood taking and blood examination was the same throughout and all the examinations were the work of one man. One fact worthy of note is that in the first attack plasmodia were never found when the blood was taken in the early part of the week, even when no quinine had been taken, whereas they were always found when the blood was taken at the end of the week, and this sometimes after the heaviest doses of quinine.

The recrudescences after the second attack I look upon as purely malarial, and the results of the administration of heavy doses of quinine bear witness in favor of this view.

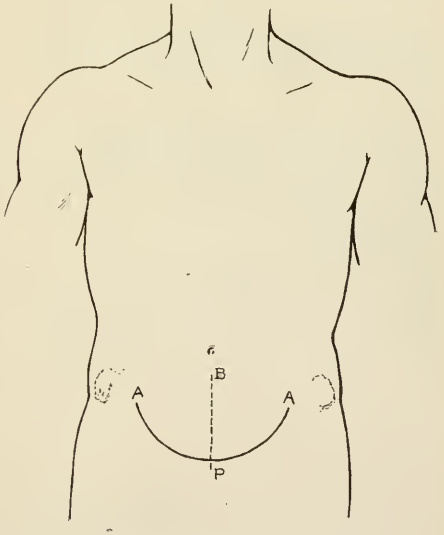
The case was such a long-drawn-out one that it has been impossible to make the history concise without making it totally inadequate for the purposes of this paper. A better idea may possibly be obtained from the bird's-eye view afforded by the accompanying morning and evening chart.

COMBINED TRANSVERSE AND LONGITUDINAL INCISION IN MEDIAN LAPAROTOMY, WITH THE OBJECT OF PREVENTING VENTRAL HERNIA.

By LEWIS A. STIMSON, M.D.,
SURGEON OF THE NEW YORK AND HUDSON STREET HOSPITALS.

Relaxation of the cicatrix after median laparotomy, amounting occasionally to actual and large hernia, is a not infrequent sequel of the operation, and causes enough discomfort to the patient to make its avoidance a worthy object of the surgeon's attention.

Many methods of operating, with a view to this avoidance, have been employed and recommended, but none seems to have won general acceptance, or to have secured the result without correlative disadvantages that have offset the gain.



An extension to this field of the principle of the intermuscular operation for the removal of the vermiform appendix, introduced by Dr. McBurney a few years ago, which has proved so successful, and which has been employed at some other points of the abdomen, seemed to me so logical and so well calculated to secure the desired result that I began to employ it two years ago, and having now used it in more than fifty cases. I desire to make the results of the experience known.*

The operation consists of a curved transverse incision through the skin, aponeurosis and sheath of the recti, followed by the usual longitudinal separation of these muscles and division of the peritoneum.

The incision crosses the median line about four centimeters above the upper margin of the symphysis pubis, and extends on each side toward the anterior superior spine of the ilium to a distance varying with the amount of the subcutaneous fat. It is then carried through the aponeurosis and sheath of the rectus on each side, its outer portions observing the direction of the fibers of the aponeurosis, and the [illegible] portion not extending beyond the outer edge of the rectus. And the upper flap thus outlined is raised from the muscles by division of its attachments to the [illegible] the linea alba. The sheath below the incision is similarly freed toward the symphysis. A few vessels perforating the sheath and the recti will need to be ligated. The recti are then separated and the peritoneum divided in the median line in the usual manner.

At the termination of the operation the peritoneum is sutured and the flaps restored and secured by buried sutures. I have recently sutured the sheath and the aponeurosis separately in the outer part of the incision. The skin is sutured with silk. If drainage is necessary the drain is placed at the center of the incision in the median [illegible] if the wound has been contaminated by contact with pus, a small rubber tissue drain is passed between the flap and the rectus on each side, emerging near the end of the incision.

The longitudinal portion of the incision can easily be extended in this manner from the symphysis two-thirds of the distance to the umbilicus, and as the division of the sheath and aponeurosis permits easy separation of the recti, the available space thus acquired for intra-abdominal manipulation is greater than it is with the same length of longitudinal incision directly through the parietes in the usual manner.

As a result, the central transverse portion of the incision is protected from a separating strain by the uninjured recti beneath it, and the longitudinal portion by the overlying fascia, which is uninterrupted longitudinally except at the ends where the separation is oblique in the direction of and not across its fibers.

If more space is needed, the flap can be split longitudinally in the median line and the incision prolonged upward as far as may be necessary.

The operations in which I have employed the method have been for salpingitis, tubo-ovarian abscess, cysts of the ovary, hysterectomy, resection of intestine, and enterorrhaphy, and in only three or four have I found it desirable to make the supplementary longitudinal incision through the flap for extension upward. These were among the earlier cases.

No case has shown any resultant laxity of the abdominal wall, and in one in which the operation was repeated for a second salpingitis a year later, the [illegible] between the recti was thicker than the [illegible] and was firmly attached to the overlying fascia.

EMPYEMA OF THE ANTRUM OF HIGHMORE, WITH PTOSIS AND DIPLOPIA. UNDERSTUDY OF THE EFFECT OF TREATMENT ON THE OCULAR DISTURBANCES.*

BY [illegible] A.B., M.D.
NEW YORK CITY; [illegible]
[illegible]

This history is presented for its unusual features and for the understudy which it furnishes. The patient was a tall, strongly built, young man of twenty-one years, in good health of body and mind. He was referred to me by Dr. [illegible] for double ptosis and diplopia of one week's duration. The ptosis was [illegible] from both upper lids. To look up he had to tilt the head backward. Confusion of vision and blurring of images almost disabled him for his work as draughtsman. At times he was obliged to close one eye to get temporary relief. There was photophobia and there was also greatly impaired vision. The onset of these phenomena was marked by a severe headache and cold in the nose. He had been subject to headaches for four or five years, sometimes as often as twice a week. Four years ago he had an attack of vertigo in which he could not raise his head from the pillow without dizziness. Two [illegible] later than he was sent to bed of a pleurisy with effusion on his left side. He had not been a mouth breather and had had no tinnitus, ear discharge, nor earache since childhood. His foreskin was free. He had a small varicocele. Some years ago he had a stricture of the urethra, caused by a kick, and was relieved by urethrotomy. His eyes had given no trouble till now. They had a normal appearance. The throat was normal also. He heard the watch at four feet with the right ear, and at ten feet with the left. The right drum membrane had no light reflex; it was scarred, but otherwise clear. The left drum-membrane was clear and had normal light reflex. The nasal septum was bent posteriorly to the right, greatly compressing the right middle turbinate. Inferiorly and anteriorly it was bent to the left and gave off an obstructive ecchondrosis of considerable length, which crowded the left inferior turbinate outward against the outer wall of the inferior meatus. The right inferior turbinate was hypertrophied. The left middle turbinate was hypertrophied, cystic and bulbous anteriorly and adherent to the outer wall of the middle meatus. It also pressed against the septum. The vision was $^{4}/_{10}$ with each eye. It was raised to $^{10}/_{10}$ with each eye by a half-diopter correction for astigmatism 15° away from the vertical. There was torsion of parallel images by the Maddox double prism test. Right hyperphoria 3°. His diplopia was greatest when looking to the right. At ten inches, exophoria 9°, abduction 20°, adduction 12°. At twenty feet exophoria 8°, abduction 10°, adduction 4°. Accommodation o.d. 40 cm., o.s. 28 cm., convergence 8 cm. The evidence was cumulative that there was here great disturbance of innervation of the ocular muscles. The correction for the refractive error was made. Some days later the tests were repeated, the patient wearing his correction, and the findings were worse. At ten inches exophoria 15°, abduction 30°, adduction 4°. At twenty feet exophoria 22°, abduction 11°, adduction 6°. Accommodation o.d. 46 cm., o.s. 45 cm., convergence 13 cm.

The first operation removed the obstructing shelf, thus freeing from pressure the left inferior turbinate. Two weeks after that the ptosis and diplopia were no better, but the muscle tests were better. At ten inches, exophoria 8°, abduction 38°, adduction 8°. At twenty feet, exophoria 12°, abduction 12°, adduction 6°. Accommodation o.d. 30 cm., o.s. 27 cm., convergence 11 cm., and right hyperphoria 12°.

---

*The idea is by no means an extension of a well known principle. That it may well have been suggested or employed by others, [illegible] I have found no report of it. Kuestner [illegible] 1897, p. 231 [illegible] recommended a curved incision along the line of the pubic hair through the skin [illegible] for the purpose of obtaining an inconspicuous scar. The principle and the details [illegible]

*Read at a meeting of the Eastern Section of the American Laryngological, Rhinological and Otological Society, at the New York Academy of Medicine, March 1, 1902.

The right middle turbinate, being greatly compressed, was removed as the second operative step. After one week the tests were still better than before. At ten inches, equilibrium, abduction 33°, adduction 10°. At twenty feet, exophoria 14°, abduction —, adduction 10°. Accommodation o.d. 29 cm., o.s. 27 cm., convergence 8 cm. Photophobia less. Ptosis was relieved so far as to allow the man to see the ceiling without tilting the head backward. After ten days the tests were the same. The patient was worried lest he should lose his place as draughtsman. His photophobia was now limited to the left eye.

The third operative step consisted in freeing the left middle turbinate from adhesion to the outer wall of the left middle meatus and crushing its bulbous anterior end. Three days later the photophobia had disappeared, and, for the first time, diplopia had lessened, so that the patient could sometimes look to the right without occasioning it. The ptosis also was less. Accommodation o.d. 27 cm., o.s. 19 cm., convergence 5 cm. Twelve days later vision had improved to $^{6}/_{10}$ with each eye. At ten inches, exophoria 5°, abduction 33°, adduction 19°. At twenty feet, exophoria 11°, abduction 11°, adduction 16°. Accommodation o.d. 18 cm., o.s. 22 cm., convergence 5 cm.

Five days after this, *i. e.* three weeks after the third operative step, the patient had profuse bleeding, and with it abundant purulent discharge from the left nostril. There had been no pus previous to this particular day. Now, however, where the middle turbinate had been freed from its adhesions, was seen for the first time an abundant flow of most foul-smelling pus. There had been no odor before this. Enough of the left middle turbinate was next removed to give free access to the ethmoid cells and maxillary sinus. A loose tampon of cotton, moistened in carbolic solution, was put in to remain two days. Its removal was accompanied by hemorrhage and free flow of pus. A similar tampon was again used. The left malar bone now, for the first time, manifested tenderness, also the two last upper left molars. With this second tampon *in situ* he was seized with alarming hemorrhage in his office, was plugged by a near-by physician and sent to my office. I found no bleeding point and sent him home without a tampon. The next morning I was called to see him at his house, where I found him blanched from bleeding that had been more or less continuous during the night. I found no bleeding point, but again put in a loose tampon, feeling certain this hemorrhage was from the antrum. No further bleeding took place afterward, but pus continued to flow from that nostril for many days. At the end of two weeks diplopia and all other eye-symptoms were gone; the discharge of pus had lessened and become thick and crusty. The tests were, at ten inches, exophoria 8°, abduction 29°, adduction 25°. At twenty feet, equilibrium, abduction 6°, adduction 33°. Accommodation o.d. 17 cm., o.s. 18 cm., convergence 4 cm. No hyperphoria. The patient was informed that the antrum might have to be curetted, yet eleven days afterward the discharge of pus had ceased, and the tenderness of the teeth and malar bone had gone. The vision was then $^{8}/_{10}$ with each eye. At ten inches, exophoria 4°, abduction 25°, adduction 30°. At twenty feet, equilibrium, abduction 7°, adduction 35°. Accommodation with each eye 12 cm., convergence 4 cm.

The patient returned for examination about a month later, when I found his vision, which had been $^{4}/_{10}$ at the beginning, was now $^{10}/_{10}$ with each eye, and it was comfortable even at close work without his correcting glasses.

It is noteworthy that this patient gave no history of headache until after the discharge of pus had set in with hemorrhages. We may suppose that pus and granulations had been bottled up under pressure in the antrum.

Not less remarkable is the fact that this trouble, so unmistakably chronic, so quickly and spontaneously cleared up without treatment addressed to the antrum. It suggests that the free discharge of pus and the free bleeding with it, so completely emptied the granulation tissue as to produce its immediate and complete atrophy and restoration of the lining membrane of the antrum to normal condition and behavior.

The hemorrhages which the patient had had during the previous four years, which were frequent and profuse, were doubtless from this same antrum.

Finally, the disturbance of the ocular muscles disappeared during the treatment before the antrum trouble was reached, showing that the latter was but partially and incidentally causative of their misbehavior.

Since making the above notes another case of antrum trouble has presented itself, equally interesting in points of similarity and difference. In this second case the disturbance was in the nature of great unrest, sleeplessness, twitchings of the limbs in sleep, headaches and invalidism, and but little eye disturbance, chiefly ciliary.

The anatomical difference was striking. At first glance this nose seemed faultless; the septum was straight, the nares were free, the middle turbinates did not touch the septum, and there seemed nothing in evidence to inculpate it except a bad odor. On closer inspection, however, both middle turbinates were found to be adherent to the outer wall of the middle meatus.

Following removal of the anterior end of the left middle turbinate, there was the same history of hemorrhages with free flow of very bad-smelling pus. Here, also, tenderness over the malar bone was manifest only after the discharge and hemorrhage. The discharge of pus subsided as rapidly as in the first case, and with it disappeared the bad odor. It was unexpected and gratifying in these cases to have prompt cessation of the antrum trouble without other treatment addressed to this cavity.

253 Gates Avenue.

A Disease of Cattle in the Northwest.—The *St. Paul Pioneer Press* says that the Minnesota State Veterinary Department is about to begin a systematic investigation of one of the most dangerous diseases that has affected the cattle of that State. The disease affects the cattle much the same as blood poisoning, and is caused by the *Bacillus bovisepticus*, a germ discovered by Minnesota bacteriologists. The investigations of the Department of Veterinarians have already discovered the existence of an acute and a chronic form of the disease. From an acute attack of the disease the cattle die within a few hours, as the germ attacks the spinal cord. When the disease occurs in chronic form life may be prolonged for three or four weeks.

A WORD ABOUT AMERICAN MINERAL WATERS AND MINERAL SPRING RESORTS.*

By JAMES K. CROOK, A.M., M.D.
NEW YORK

The practitioner who will take the trouble to inquire will find that the mineral waters of the United States do not suffer by comparison with the best that the old world can afford. In the appended table, which comprises in each class half a dozen examples of the most potent as well as the most famous European springs, it will be observed that in every class save one the waters of our own country are richer in mineral ingredients than those of Europe.

A further search will show that not merely in potency of a few individual springs, but in general variety of mineral ingredients and in all the elements which go to make up an attractive analysis and a useful medicinal water, we have within our own borders, with the single exception of the sulphated salines, better waters and more of them than are shown by any European work on this subject. It cannot be denied that in the saline purgative group our native waters do not equal in mineral richness those to be found in Europe. We have no analogues of the Hunyadi János, the Carabaña, the Apenta or the Rubinat group. There are nu-

TABLE SHOWING COMPARATIVE POTENCY OF REPRESENTATIVE AMERICAN AND EUROPEAN SPRINGS.*

I. ALKALINE WATERS.

AMERICAN	GRS. PER U. S. GAL.	EUROPEAN	GRS. PER U. S. GAL.
Saratoga Vichy	367.32	Vichy, France (Grande Grille)	311.42
Ukiah Vichy, Calif	268.45	Fachingen, Nassau, Ger	224.51
St. Louis Spring, Mich	227.14	Ems (Kessel Brunnen)	169.75
Manitou, Colo. (Navajo)	182.23	Apollinaris, Rhenish Prus.	157.76
California Seltzer	187.15	Weilbach, Hesse, Ger	165.27
		Wildungen, Ger (Stadt-Brünnen)	67.44

II. ALKALINE-SALINE.

AMERICAN		EUROPEAN	
Ballston Spa, N. Y. (Artesian Lithia)	1123.35	Vals, France (Désirée Spr.)	545.88
Waconda Spring, Kansas	1120.65	Bourbonne (Haute Marne, Fr.)	491.47
Saratoga, N. Y., Hathorn	888.40	Luhatschowitz, Moravia	418.04
Americanus Well, Mich	503.90	Bilin, Bohemia (Joseph's Quelle)	304.47
Borland Mineral Well, W. Va	432.28	Selters, Nassau, Ger	228.14
Dixie Spring, Tenn	313.74	Obersalz-Brünnen, Silesia	118.58

III. MURIATED-SALINE.

AMERICAN		EUROPEAN	
Glen Springs, N. Y. (Neptune) (Used for Schott-Nauheim treatment)	10503.08	Springs of Nauheim, Ger (Friedrich-Wilhelm's Quelle)	2148.87
Geuda Springs, Kansas	1314.78	Kreuznach (Oranien-Quelle)	1084.12
Eureka Springs, Calif	1800.27	Homburg, Ger (Eliz. Brunnen)	870.06
Sweet Springs, Mo. (Akesion Spr.)	1061.94	Harrowgate, Eng	864.43
Lodi Artesian Well, Ind	672.45	Cheltenham, Eng	644.00
Upper Blue Lick, Ky	660.14	Wiesbaden, Ger (Koch Brunnen)	507.70

The strongest waters of this class on the globe are found in the United States. Notable examples are the Byron "Surprise" Spring of California, containing 18,773.73 grains, Clark's Red Cross Mineral Well of Michigan, 17,825.27 grains, and the St. Clair Mineral Spring of Michigan, 17,904.60 grains per U. S. gallon.

IV. SULPHATED-SALINE.

AMERICAN		EUROPEAN	
Clark's Riverside Springs, Mich	7318.97	Carabaña, Spain	7391.23
Castalian Springs, Calif	4422.25	Rubinat (Serre), Spain	5266.64
Blue Lick Springs, Mo	610.30	Apenta, Hungary	2541.09
Crab Orchard, Ky., Epsom Sp.	401.43	Pullna, Bohemia	2010.45
Gibson Mineral Well, Texas	329.65	Friedrichs-Hall, Ger	1550.92
American Carlsbad, Ill	259.99	Seidlitz, Bohemia	897.59

V. CHALYBEATE.

AMERICAN		EUROPEAN	
Matchless Mineral Wells, Ala	167.91	Brighton, Eng	14.40
Overall Wells, Texas, No. 2	144.90	Spa (Pouhon) Liége, Belgium	5.42
Brown's Wells, Miss., No. 1	36.52	Schwalbach, Nassau, Ger (Stahlbrünnen)	3.74
Gaylord & Gulick's Springs, Va	31.63	Tunbridge Wells, England	2.22
Oak Orchard, N. Y	28.62	Pyrmont, Waldeck, Ger (Trink-Brünnen)	2.48
Bath Alum, Va	26.78	St. Moritz (Grande Source), Switzerland	1.38

The figures refer to the amounts of ferruginous salts per U. S. gallon. The U. S. possesses innumerable chalybeates of the milder grades.

VI. THERMAL WATERS.

AMERICAN.		EUROPEAN	
California Geysers	150° to 214° F.	Wiesbaden, Ger (Koch-Brunnen)	155° F.
Hunter Springs, Mon	148° to 168° F.	Baden-Baden, Ger (Haupt-Quelle)	155° F.
Arkansas Hot Springs	76° to 157° F.	Gastein, Salsburg, Austria	87° to 160° F.
Glenwood Springs, Col	124° to 126° F.	Bagnères-de-Luchon, France	131° F.
Virginia Hot Springs (Boiler)	108° F.	Nauheim, Ger	98.5° F.
North Carolina Hot Springs	96° to 104° F.	Wildbad, Ger	94° F.

Some of the undeveloped thermals of the Rocky Mountain States and California issue from the earth at a boiling temperature.

*Read before the Section on General Medicine of the New York Academy of Medicine, May 20, 1902.

*Tabulated in accordance with the author's classification in "The Mineral Waters of the United States," Philadelphia and New York, 1899, and in "Hare's System of Practical Therapeutics," 1901.

merous excellent waters of this class in the United States, however, and with the possible disadvantage of requiring somewhat larger liquid dosage, they possess a therapeutic efficiency not exceeded by any of the foreign waters. It is interesting to note in this connection that one of the most celebrated of the European springs, and undoubtedly the one most largely visited by Americans, owes most of its virtue to the presence of about 2½ drachms of sulphate of soda, or Glauber's salt to the gallon. Nor can it be maintained that numerous of our mineral spring resorts are inferior to those of the old world with respect to diversity and salubrity of climate, to beauty of scenery, or to any of the attractive features which Dame Nature supplies. Furthermore, not a few of the American spas are fully supplied with spacious and elegant hotels, luxurious bathing pavilions, and all the facilities for recreation and creature comfort to be found at the best equipped European watering places. But notwithstanding these unquestionable facts, and the added advantage of nearness and easy accessibility of our home resorts, the mineral waters in America do not occupy the high plane of therapeutic utility which, for many generations, they have held in Germany, France, England, and other countries of the old world. With each recurring season we behold the hegira of increasing numbers of our valetudinarian fellow-citizens, who are willing to undertake the expense, the fatigue and the hazards of a long trans-Atlantic and overland journey in order to secure the advantages of mineral waters no more potent for medicinal purposes than those within our own borders. The reason for this undesirable state of affairs lies very largely at the doors of the medical profession. It is scarcely a misstatement to say that this subject is not taken seriously by most practitioners in the United States. It is apt to be ignored or scoffed at by many. In Europe, on the other hand, balneotherapy as well as climatotherapy is a recognized branch of medical education, and these subjects are embraced in the curricula of all the leading universities. Some knowledge of the use of mineral waters in the treatment of disease is made essential to receiving a diploma of graduation. As far as the author can learn, not a medical institution in the United States either teaches balneotherapy or requires any knowledge of it from its graduates. The young physician begins his career in ignorance, and unless he is led by fortuitous circumstances to make some study of the subject, his chief knowledge of mineral waters is apt to be derived from advertising circulars, many of which are decidedly quackish and better calculated to sour and prejudice the mind of the practitioner than to gain his respectful consideration. This state of affairs is greatly to be deplored.

These natural therapeutic aids are cheap and abundant in the United States. Almost every State possesses one or more valuable water or attractive mineral spring resorts. With every allowance for the gross exaggerations of those in interest regarding the value of some individual spring, it cannot be denied that certain diseased states, especially those of a chronic nature, are greatly benefited by a systematic course of properly-selected waters, and there is not a practitioner in our broad land who may not occasionally avail himself with advantage of their aid. At a well-regulated European spa a great majority of the persons one finds drinking the waters are acting under the advice of a practitioner at home, and while at the spring are directed by the resident physician. The best of discipline prevails. There are certain specified hours for rising, for drinking the water, for exercise, for meals, for bathing, and for recreation. The quantity of water consumed, the temperature of the bath and its duration, the character of the dietary, etc., are all looked after by the local physician. How does this compare with the régime at our American spas?

It might almost be said that no régime exists on this side of the ocean. At most of our watering places the observer will find that 80 or 90 per cent. of the visitors are acting entirely under their own guidance. If the consumer be a robust person, or the water of mild or feeble character, no harm is done, but in far too many instances one finds a diseased or debilitated individual, whose condition merits thoughtful consideration, drinking the waters of a powerfully-mineralized spring with no other rule of action than that provided by his own whims or ill-founded notions. The drinker rises when he pleases, eats what and when he likes, goes to bed when it suits him, and is ready to accept random suggestions from any casual individual he happens to become acquainted with. In many cases he throws pills, powders, and potions to the winds while at the spa, and appears to consider it his chief object in life to keep himself as full as possible of the water, which, perhaps, is exactly the kind of medication that will do him the most harm. The results achieved here cannot, of course, compare with those they get at Carslbad, Baden-Baden or Homburg.

The obvious remedy lies with the medical profession. Let the practitioner give a little serious thought to the matter. He will certainly come across occasional cases which will derive more benefit at a summer resting place, possessing a suitable mineral water, than at one not so supplied. I need not in this place urge the advantages of a change of scenery and surroundings during the summer months. The escape from the dust and smoke and turmoil of the busy city, with the thousand and one cares and worries and anxieties of home and business, to a cool rural retreat with fresh and fragrant country air or invigorating mountain breezes and pleasing scenery, is attended by results well known to all. Most persons experience a speedy improvement, quite regardless of the character of the water they drink. At many of our spas all of these desirable features are supplemented by the further advantage of one or several varieties of highly-mineralized springs.

It seems to be a plain proposition that an obstinate case of chlorosis will improve more rapidly at a summer resort possessing a potable bicarbonated iron water than at one not so supplied. Chronic dyspeptics thrive wonderfully on the muriated alkaline salines, while the influence of a potent alkaline spring will soon become manifest in an old rheumatic or gouty case. Without going into therapeutic details, it may be said that these waters always act better at the spring than in the city. It is the combination of getting away from home and worry, sweet country air and surroundings, and a good water, which does the work.

It is the province of the physician to set the people aright in these matters. He should select the cases which require, or would be likely to receive, benefit from spa treatment. He should be able to direct his patient regarding the routes of travel, and he ought to possess some information pertaining to the climatic and scenic conditions, the heighth above the sea level and nature of the accommodations, the facilities for recreation and amusement, etc. It must be confessed that there are so-called resorts in America as well as in Europe where life would be a burden to a visitor from a locality possessing the adjuncts of modern civilization. Above all, the practitioner should have accurate knowledge as to the chemical analysis of the fluid he proposes to have his patient drink.

At nearly all of our better American spas competent resident physicians will be found who are prepared to give proper advice to persons wishing to take a course of the waters. A letter from the family doctor at home to the local physician of the springs, with some details of the case, is a valuable possession to every person visiting a spa with the intention of securing the largest measure of benefit, and he should, after arrival, submit to at least one examination by the resident physician before beginning the use of the waters or baths.

It is only by measures of this kind that a helpful branch of therapeutics will ever be rescued from the hands of ignorant and unscrupulous charlatans, or attain in America the dignity and usefulness which it has for centuries occupied in Europe.

THE CHARACTERISTICS AND TENDENCIES OF MODERN MEDICAL PROGRESS IN AMERICA.

By JONATHAN WRIGHT, M.D.,
BROOKLYN, N. Y.

Amidst the general congratulatory chorus which accompany the announcement in the lay and secular press of large sums of money donated to the advancement of science, any doubt expressed as to the ultimate results which are expected to be of such immense service to humanity would seem a little discordant. Nevertheless a free and unprejudiced criticism, especially if well founded in the records of the past experience of the world, cannot fail to have in the end a beneficial effect upon the conditions which usually and which often are necessarily attached to such expenditure. The musty records of many a charitable and educational institution in Europe display evidence that public-spirited men of bygone ages believed the objects to which they devoted their bequests would continue to be worthy of the regard of succeeding generations. Many of these charters of gifts are now mere curiosities for the antiquary. But in this country in the last thirty years the number and dimensions these donations have attained is a new phenomenon, at least in the domain of science, and a parallel can only be found in history in the profusion with which gold in the early pre-Renaissance period was poured out for the salvation of the donor's soul. This lavish expenditure of wealth, suddenly acquired, is easily explained when we realize that its selfish and sordid sequestration, or its equally sordid expenditure for personal gratification, means to some extent social ostracism in the preponderating class to which the donor necessarily belongs, that of self-made men. This generosity is still further stimulated by the consideration that this country, practically, lacks that protection to hoarded wealth which is necessary to prevent its dissipation by the incapacity of the succeeding generation. However that may be, the sudden devotion of this wealth to the aims of science is a subject which is a legitimate topic for dispassionate discussion unaffected by any enthusiasm we may naturally feel for a country or an age where the phenomenon is manifested. We have every reason to believe that, properly utilized, this tendency is an augury of great future good to the development of civilization, but if blindly dealt with or selfishly appropriated to the temporal advantage of a narrow hierarchy of science, for which the history of civilization was a precedent in theology, it may disappoint our roseate expectations, and even act as a curse rather than be a blessing to the advance of science. The responsibility now rests with science to see to it that a better use is made of the power which money wields than did the Church in the period which elapsed between Gregory the Great and Luther. History, though constantly repeating itself, is always presenting a different face. We are no longer in the age either of Gregory or of Luther. We are in the age of unbridled democracy, the age of mediocrity. This train of thought reminds us of the somewhat gloomy prognostications of Mill and Huxley fifty years ago as to the evil tendencies of modern democracies. To a certain extent they have been verified. No thoughtful observer of modern social life can fail to observe the increasing prestige attached to mediocrity in thought and action. It is the era of mediocrities. There never was a time when mediocrity by industry, complaisance, and subserviency so easily achieved distinction. There never was a time when the world travelled forward so en masse, so without leaders, as to-day. There never was a time when departure from ordinary thought and action was so liable to be regarded not as the eccentricity of genius, nor accepted as the proof of a superior understanding, but as the vagaries of an individual whose proper abode is a sanitarium for the mentally unsound. And an individual who obtrudes his personality is sure to become the object of aversion and dislike. The word crank is a modern term which has entered our lexicons for frequent application to the human being who thinks a little differently from the various majority. It is sure to be applied in an undesirable spirit of resentment and hostility to him who entertains ideas which the common run of men are unable to comprehend or unwilling to examine, no matter how full of truth they may be.

There is no more striking evidence of this, certainly none more familiar to the reader of current medical literature, than the observation of the readiness with which the reporter or rather the abstracter of a medical discussion seizes upon the platitudes and commonplaces of the speaker, and invariably misses any spark of originality which may fall from his lips. For this, instead of being crucified, he is commended, and his admiring clientèle accept as the whole truth his boast that he has crammed into his paragraph the gist of thoughts that he is incapable of understanding.

Another observation, familiar enough to the medical man, is the melancholy contemplation of the abundant deadwood which has drifted into medical faculties, hospital staffs, and exclusive medical societies, carried there not by the strong currents of laborious human endeavor in the streams of original research or of sturdy service in the ranks, but by the numerous eddies of subserviency and self-effacement, family influence and personal geniality, persistent plodding and skilful diplomacy. This, of course, must always have been so to some extent, but never has it assumed the proportions which may now be observed everywhere. The day of stimulating contrasts is no more. We cannot but believe that this suppression of original and unwonted tendencies of thought and action in the world at large has robbed life of much of its highest charm and interest, while we rejoice that it has, at the same time, expelled from life still more of its miseries and degradation. One can run a very much better chance of dispelling ennui in the hut of the rustic and the boor, in the tenement of the beggar and the thief, than in the tiresome club and somnolent drawing-room of social respectability.

Now I am not wandering from my subject in the least. This is not only strikingly true of the social, the political, and the purely literary world, but it is so true of the artistic world that it has all but destroyed the highest order of poetry, painting, and plastic art. Not less true is it of the world of science. It is not solely because of the fact that we are a generation devoted to the microscope, the test tube and the stethoscope in medicine, that the didactic lecture room is thought to be waste space (and it frequently is) in a modern college building; it is because, to paraphrase a witticism of De Amicis, while a thousand students may enter it daily, an original idea only intrudes once in ten years. There has scarcely been a time in medicine when those who stand foremost among its devotees have been so hostile to new ideas which appear on their horizon. The explanation of this is to be sought in the preceding remarks as to the characteristics exhibited by modern democracy—the intellectual tyranny of the majorities. Nothwithstanding these regrettable evidences of a new order of things, there is a bright side to the picture, and there can be no denying the fact that the sum total of the happiness of civilized mankind has been enormously increased by it.

The expenditure of gifts for scientific progress is usually intrusted to men who have long since attained eminence in the lines of work to which aid is to be extended. They have, as a rule, done their life work with formulæ which are soon to be discarded. They naturally believe that their way is the proper one in which to achieve the success in the future which they have attained in the past. It is possible that there may be directions of human endeavor, where this belief may be well grounded. This is not the case in science. Many centuries ago the world was already old enough for Aristotle to declare that in science authority is the worst foe of progress. Our laboratories, our schools, our clinical instruction are, as they should be, for the most part in the hands of those best adapted to teach the coming generation the wisdom of the departing one, but as for original research, as for the discovery of the men who are to solve in the future the mysteries of the present, we cannot rest so assured.

A board of supervisors for progress in medicine would be very apt to become a board of supervisors for the perpetuation of error. The unfolding of any great innovation in scientific principles must necessarily be accompanied, even to some extent preceded by the undermining of those bases upon which the middle aged and elderly men, who are sure to be the supervisors, have erected their own superstructure. They are sure to regard any further prying into the foundation of things a useless attempt to approach nearer to a knowledge of the first Great Cause, an almost impious, at least a foolhardy, attempt to know the unknowable.

Let us imagine, if we can, members having been selected from the notabilities of the universities of sixteenth-century Europe to guide, at the dawn of the seventeenth, the youthful Harvey in his investigations of the circulation of the blood. Let us fancy, if possible, a committee appointed from the schools of Vienna and Berlin to see to it that Schwann and Schleiden were guided in the path which led to the foundation of cellular histology. It is, in view of the facts, a severe strain on the agility of one's imagination, but let us try to think of the schoolmen to Oxford and Cambridge formed into a coterie to judge and direct the work of Darwin and Spencer in their young days. Let us think of the University of Paris supervising the preliminary work of Pasteur and Tyndall. Could human ingenuity devise a better way of smothering the genius of these men than to impose upon them the advice of their predecessors as to which way led the path towards the Truth?

All this seems incongruous and highly ridiculous, because we realize that the great work which these men have done has been accomplished almost invariably in the face of unsympathetic skepticism, or even the active discouragement and opposition, of men trained in other lines of thought. We might almost believe that if this had been the way depended on in the past for the propagation of original research, the blood might still be surging back and forth through the arteries for us, and the mutability of species might still be imperfectly apprehended. We are not, therefore, to expect that a new basis for pathology will be found in the well-trodden paths of the present; we can not hope that men trained in these paths are going to be able to point out to the youthful investigator where he is to blaze a new one. Such a phenomenon would be absolutely contradictory to the normal trend of human events.

Now the valid defense and the proper answer to the critical remarks which I have ventured upon is that no one would suppose that man, had he even the fabled wisdom of the serpent, can devise a way to avoid results springing from his own imperfections. The propensity to err, the certainty that any man or any coterie of men will err in their judgment, has become a mere platitude familiar to every schoolboy. Unfortunately, obstinate persistence in error, and, still worse, the selfish grudging of merited aid to those who shake our cherished beliefs and theories by the demonstration of new facts, are not, by any means, apt to be absent from the springs of action which govern the men who are nearly always selected to guide human endeavor toward its goal—the Truth. This is unavoidable, and such endowments as we have been considering cannot pretend to the task to uncloaking genius, no matter how apt they may be to recognize talent. In this sense of the word we may and must admit that devices for the encouragement of original research are misnomers. The poet, Virgil, exclaimed of old:

> "Felix qui potuit rerum cognoscere causas."

Doubtless this answer is true enough. Little can be done to alter human nature, but something can be done to alter its manifestations, which indirectly will have a powerful influence for the good on the progress of science in America. That something is the raising of the ideals for which we strive. The indications are that this is being done, and in all circles of life the realization is spreading that it is the substance and not the name which is worth striving for, that work itself is the reward, and not simply the means, of life.

What institutions endowed with such unprecedented wealth can do, and what they are doing with enormous energy and moderate success, is filling out the details of schemes forecasted by men who have, for the most part, worked in more untrammelled ways. This is not to be undervalued. It supplies tools to the workman who comes later. It opens up new vistas to the eye of genius. We need not regret the advent of conditions which are preparing to make the work of the future architect more effective, even though we understand it makes the recognition of his work more difficult.

While, therefore, it would be captious folly to deny the utility, even to the highest ends, of endowments for so-called original research, judging from the past, it is not from such influences as they supply that we are to expect radical advance in the principles on which pathology and etiology are based. And yet this is what we need more than anything else, more than ever before in the history of medicine since the overthrow of the Galenic pathology. Never before in the history of the world have there been so [illegible] such an enormous accumulation of unclassified facts awaiting correlation. Never before has the knowledge of these facts been so generally diffused with other knowledge throughout the civilized world. And yet beyond man['s] [illegible], is the time at his disposal to grasp all the isolated facts which may be gathered in any one of the special fields of medicine, however contracted that field may be. There is not so much [illegible] as to the lack of the proper form of classification which should simplify our comprehension of them. The fewer facts a man has to [illegible] which he [illegible], the better.

Conjecture as to the direction in which that radical forward step is to be taken, possibly has already been taken unrecognized, would be a mere loss of time, a *jeu d'esprit* were it not that such exercise must naturally tend to keep our minds and our sympathies in a receptive state. Now that they are beginning with how trustworthy evidence I do not know to tell us the size and shape of molecules, and to even surmise the existence of smaller particles of matter than atoms, but especially now that the realization is dawning on us that there is a world of intracellular life, and that the cell is not necessarily the unit of life in the animal organism, we may hope that the advancing knowledge of the law of physics as well as of biological activities will carry us beyond the bacterial conception of the origin of disease. To those who have studied the changes in intracellular life under varying conditions, it seems evident, as I have said, that the cell is no longer the microcosm, but the macrocosm within which a world of vital activities is at work beyond our ken, armed as we are with objectives of enormous resolving power. To those who have studied the objects which Sansfelice, Gaylord, and Schuller believe to be the organisms of cancer, and much of the rest of the world believe to be cellular degenerations, it is apparent that the bits of protoplasm which grow within a cell may also have an extracellular vital existence. They may be seen, usually within the cell body, but sometimes without it, varying in size from the merest visible speck under the highest magnification, apparently looming up from the invisible world, up to a size easily detected by low objectives, presenting every evidence that they are in a process of growth, structureless so far as we know, growing like a crystal by the mysterious accretion of matter from their environment. Whether we call these bits of protoplasm degeneration or microphytes, and whatever their etiological significance may be, it is evident that they are not cells, in the definition of the word as we have hitherto accepted it, but matter, the mystery of whose vitality we cannot now fathom. Evidently, also, they are not such microorganisms as we are accustomed to see multiply and grow in and out of the body.

As I write I read in the editorial of a world-wide circulating journal that "the pathologist of to-day can no more conceive of organized structure exhibiting vital phenomena, whether the simplest or the most complex, without reference to the cell, than we can conceive of the sun apart from light and heat." If this were so, it would only prove the limitation of the conceiving powers of the pathologist. The extension of those is what we need. Hæckel and his school have long since conceived of such life, and though we may be unwilling to follow the visionary theories of Monism, we can not escape the conviction that the cell is a comparatively complex, though as yet an unresolved organization of protoplasm. "Omnis cellula e cellula" has been a precious formula by the aid of which all the problems which have been solved in the last forty years have been worked out in the animal and vegetable organisms, but there is no proof that the formula has any application to the problems of life itself. Indeed, we now have no conception of the beginnings of life as we understand it in the animal and vegetable kingdoms without an admission of the heretical and well-[illegible] doctrine of spontaneous generation, for certainly if evolutionary doctrine is a fact, if the fact of the mutability of the forms of life [illegible], then life has not only been a [illegible], as the theologians tell us, but there is every instant a [illegible] where matter is becoming endowed with vital energy which has the power to propagate its kind.

I have gone thus far, not even in the way of venturing a hypothesis, which would be presumptuous in me, but in advancing an illustration that for further advances in biology little reliance is to be expected from two generations whose knowledge is based on doctrines which must give way before the onslaughts of progress, just as in the past all doctrines have been demolished by continued revelations of the truth.

1 [illegible] Street.

Bacteria on Mont Blanc.—In the Comptes Rendus of the Paris Academy of Sciences, M. Jean Binot prints an account of his researches in the observatory on the summit of Mont Blanc, where he has been conducting bacteriological investigations at the highest altitude yet explored. As was to be expected, the air on the summit, away from the observatory, contained scarcely any bacteria whatever, only from four to eleven being detected in as much as a thousand litres, while in somewhat smaller volumes none whatever was found. As a rule, at lower altitudes the number of bacteria increased, as, for instance, at the Plan de l'Aiguille fourteen, and at the Montanvert forty-[illegible] were found in a thousand liters. Inside the observatory, in which M. Binot spent five days, from 200 to 54[illegible] microbes were found in the same volume of air, these being probably introduced by M. Binot and his companions during their temporary invasion of the building.

The investigations were not, however, confined to the air on the top of the mountain, but included also bacterial examinations of freshly-fallen snow, old snow, ice on the surface and below, glacier water, and mountain streams. Freshly-fallen snow, even when sampled in large quantities, frequently contained no bacteria whatever, while in snow which had lain for some time usually only from one to two individuals were discoverable per cubic centimeter; at the foot of the glaciers the surface snow contained rather more, the number varying from six to sixty-five per cubic centimeter, at the Mer de Glace. Glacier water is usually very pure, and, like the glacier ice from which it is derived, was found to contain a number of yeasts and some streptothrix, but while high up such water contained but from three to eight bacteria per cubic centimeter, a stream at the foot of the glacier des Bossons contained ninety-five, while the water of the River Arve, at Chamonix, was found to have as many as 7,550 per cubic centimeter. Altogether, M. Binot examined 121 samples of air, ice, snow, and water, and isolated no less than 300 different varieties of microbes, one third of which number he was able to identify as having been already studied and described, and the residue are being carefully investigated by him at the present time. Even the alluring and beautifully clear and crystalline spring water on the Montanvert Road was condemned by being found to contain a dozen virulent colon bacilli in a cubic centimeter. Doubtless, this pollution was due to the herds of cattle which graze on the mountain pastures.—*New York Evening Post.*

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR

PUBLISHERS

WM. WOOD & CO., 51 Fifth Avenue

New York, June 28, 1902.

THE AILMENT OF THE KING.

THE latest reports from Buckingham Palace, up to the time of going press, are to the effect that His Majesty, King Edward VII, is in a fair way toward recovery from his recent attack of so-called perityphlitis.

With all due allowance toward our English brethren for their persistence in the use of an otherwise obsolete term, it is fair to assume that the malady in question was an ordinary appendical abscess, taking its usual course, and was treated in the customary way by simple incision.

Although it may be admitted that perityphlitis as an independent disease may exist, but its manifestation as such is so rare that practically we leave it out of consideration in diagnosticating the most common of all the phlegmons occurring in the right groin.

From the American point of view, which is certainly the advanced one regarding the pathology of appendicitis, the infection of the vermiform process is the starting point of all suppurative conditions involving neighboring parts. The only disproof of this assumption in the King's case would be the demonstration that at the time of the operation the appendix itself was free from disease. The great probability, however, is that the appendix could not be found, having been previously destroyed by the sloughing process associated with the formation of the abscess. This would explain the reason why no mention has been made of the removal of the offending organ and why the operation itself consisted in a mere incision for the evacuation of accumulated pus. Evidently that was the only thing to do under the circumstances as giving the patient the best chance for a safe and easy recovery. In a word, it was following the surgical rule in such cases to leave the remains of the appendix alone when they cannot be easily reached, but more especially when, as is most commonly the case, they form a part of the wall of the cavity.

If we may judge from accounts in the British medical journals, the actual diagnosis of an abscess was not made until a few hours before the operation, notwithstanding the fact that the patient must have suffered from the usual symptoms of such a condition for several days.

In analyzing the clinical symptoms from the time of the review at Aldershot on June 14, it seems quite evident that the ailment declared itself at that time with chill, colicky pain, nausea, and faintness. In vew of subsequent events, many risks were taken in allowing the patient to be moved from one place to another during the formation of the adhesions which were to constitute the protecting walls of the forming abscess.

It is hardly conceivable that the abscess formed itself within the few hours preceding the operation, as intimated in the cable dispatch to the MEDICAL RECORD. Certainly, as a rule, large abscesses of this kind form rather slowly and give early local evidences of their existence in the shape of rigidity of overlying abdominal muscles, circumscribed tumescence, and distinct localized pain on pressure. It is not at all likely that these significant symptoms escaped the notice of the distinguished medical advisers, but they were evidently powerless in preventing their royal patient from taking the risks indicated.

Inasmuch as Lord Lister is reported as intimating that a secondary operation may be necessary in the case, it seems probable that the appendix itself was not removed. If so, it was certainly good surgery. Those who have had the largest experience in appendicitis are almost unanimously in favor of such practice, and it is only in exceptional instances, in which there is continuous and distressing pain from old and faulty adhesions, or persistently recurring suppuration, that any attempts are made to interfere with nature's usual method of repair. It might almost be considered a discourtesy to the founder of modern asepsis to compare the old-time method of drainage by tubes with that of the American plan of packing the wound with sterilized gauze, but the good results of the latter are so manifestly overwhelming as to afford us the excuse for making apparently invidious comparisons.

The wound being in good condition, and there being no fear at present of septic peritonitis, the prospects for ultimate recovery must be mainly based on the integrity of the heart and the normal action of the kidneys. Hence an accelerated pulse-beat or loss of consciousness from coma would be indications of most ominous import.

THE OUTLOOK FOR THE YOUNG PRACTITIONER.

To the thousands of young men who have graduated from our medical colleges the great problem presents itself as to how a proper start is to be made in practice.

It must be admitted that with the number already in the field eagerly striving to the same end the difficulties in the way are proportionately great, and brilliant success must necessarily be limited to comparatively few of the eager aspirants. It is equally plain that many avenues heretofore opened are closed to them and old-timed methods must take the place of new ones.

In a large city with a growing population it was sufficient to settle in some of the poorer districts and trust to the casual calls to accidents and the sudden attacks of sickness which should in a natural way introduce them to their future patrons. Now, with dispensaries everywhere, hospitals and ambulances ready for all emergency cases, health board doctors with free vaccination, and million-

[illegible] pays for so-called charity to the [illegible] by [illegible] himself restrained to such [illegible] are thus left for him. It is sad that he expects a large income, but that he should be assured a decent livelihood.

For the great credit of the men who succeed in spite of these handicaps, it must be said that they have abundance of patience and a laudable industry, [illegible] work against heavy odds. A very few may become famous and gain the topmost round of success, but the vast majority must be content with the mere reward of work for the work's sake.

Still the pursuit of a living by the ordinary practice of the profession should be the legitimate aim of every one who expects to be a physician in the broader and truer sense. Thus it is better to face these in the beginning than to shirk them by the ordinary makeshifts of outside occupations. The proper and independent way is to live by legitimate professional work and be contented with nothing short of it. What is easy at the start in obtaining salaries for special professional services is hardest in the end when the incumbent finds himself a mere medical clerk for a life insurance company or hanging to a similar salaried official position.

When such positions must be taken to tide over pecuniary difficulties it is best that they be merely temporary, having the main end of practice in ultimate view, otherwise there is little hope for self-advancement, inasmuch as promotion is very slow in the army or navy, and health boards, as a rule, are merely political machines in which favoritism and pull rule against service and merit. The best that can be obtained is the position of chief of a department, the highest salary for which can never equal the income of an ordinarily successful practitioner.

Everything bearing on final success depends on the ability to work and wait during the early years of struggle. If the young man has sufficient capital to live for the first few years independently of his practice, he has the better chance as compared with him who starts with nothing. In fact, it has been often advised that no man nowadays should make up his mind to study medicine with any idea of meeting his immediate expenses by any practice he can obtain during that period of hard working. The disappointments from an opposite course are too numerous to mention and many, by force of circumstances, have been compelled to seek work in other channels and thus waste the time spent in hard study and useless preparation. Fortunately, the fascination of professional work holds many to their original purpose in spite of early difficulties and comparatively small pecuniary returns in the end. The valiant workers in city and country attest this fact, and to them the medium of to-day owes its dignified position, its widespread influence and its true progressive spirit. The very fact that medicine is a grand profession makes it a very poor trade from a purely commercial standpoint. Fortunately the physician is satisfied with little, but if he works hard for it, especially in his earlier career, he is apt to gain it. The main point of all, however, is to stick to his business pure and simple from beginning to end and then to vindicate his right to be one who depends solely upon his profession for a living and will be content in nothing short of it.

The greatest mistake of all is to start in a specialty without being thoroughly grounded in general practice. There are too many such young men, who, lured by the hope of quick gains and relatively large incomes, are waiting in vain for office patients while their classmates are taking anything that comes and laying the broader foundations of really successful work in the future.

The question is often asked, where shall I settle? This cannot, of course, be answered in a general way. Each one must find his place for himself whether in city or country. The only difference is that in the former place, if he is willing to wait longer, he can in the end earn more. [illegible], however, with the ordinary all-round man, the gross [illegible], considering relative expenses, are about equal in both places. In either case the acknowledged leaders are the only ones that command the largest fees, and the top of any profession has comparatively small standing place. The history of them now is the same regarding the moderate sums earned when commencing practice, and the lesson thus taught is obvious enough. The young man more than ever must compete for comparatively cheap service until age, more experience and more business place him on the higher level of worth to himself and his patients. It would require but few such calls daily to pay his office rent and board, and even among the poorer classes there are some self-respecting persons who would gladly patronize him on such a basis than receive the ordinary machine treatment of most of the dispensaries. And even if he should do some missionary work in cultivating an independent spirit among his clients he would only be using legitimate means in protecting himself against many of the grosser and more flagrant abuses of medical charity that tend so surely and directly to ruin him at every turn. So much then for the ordinary opportunities of the medical youngster.

THE PRESENT CONDITION OF KING EDWARD VII.

(Special Cable to the Medical Record.)

London, June [illegible], 1902.

To the Editor of the Medical Record:

Sir:—From the most trustworthy sources it is learned that the operation on His Majesty King Edward VII. has been successful in all respects, and that no complications have declared themselves.

The general medical opinion now is to the effect that ultimate recovery will be assured unless there be some unforeseen turn in present symptoms. There is no foundation for the rumor that malignant disease caused the intestinal trouble. The latter is designated here as perityphlitis, a term in general use to express the condition known as appendicitis in America.

No definite statement has yet been made regarding any actual disease in the appendix.

The recent illness of the King was at first attributed to an attack of rheumatism, and the usual treatment for that affection was instituted. During the early progress of the illness the pain became localized in the right side of the abdominal region and was attended with slight elevation of temperature and increased rapidity of pulse.

On the journey to London the pain became very much aggravated with sudden rise in temperature, and the diagnosis of localized suppurating process was made. Sir Joseph Lister and Sir Frederic Treves were then called in consultation and the operation was decided upon.

The wound is in a healthy and quiescent condition and there are no indications of septic peritonitis. The abscess was of large size and was opened in the usual manner by direct incision through abdominal walls. The inflammation is reported to have been limited to the site of the abscess.

The reports that the King is on verge of collapse have no possible foundation. At no time since the operation has he been in special danger.

Cholera in the Philippines.

Cholera for a considerable time has been reported prevalent in the Philippines, although its ravages have been reported as almost entirely confined to the native and eastern population.

According to the *New York Herald* of June 22, a report just received from General Chaffee by the War Department at Washington shows that the army in the Philippines is seriously affected by the cholera raging there. The report referred to states that twenty-two enlisted men died of cholera in the two weeks between April 23 and May 6.

Despatches sent out from Manila on June 21 stated that cholera was spreading in the islands. Thirty-five cases were reported in Manila on June 19 and twenty-eight deaths. The totals up to June 21 were 1,490 cases, and 1,197 deaths in Manila, and 6,959 cases and 5,098 deaths in the provinces.

This news is of a very grave nature, for if cholera of the type common in the far east gains a foothold among the American troops the probability is that it will spread with great celerity and cause a large mortality.

Asiatic cholera is one of the most dreaded diseases of the East, and shares with the plague the undesirable notoriety of claiming more victims than any other malady of that region. However, the United States Military Medical Department of the Philippines may be relied upon to take every step known to sanitary science to stamp out and to curtail the spread of the disease.

Protection of Wild Birds.

In the editorial pages of the Medical Record reference has been made on several occasions to the need of protecting the wild birds of this country and to the efforts of the American Ornithologist's Union to compass this object. The Union in question has recently issued its report for 1901, which shows that eleven States prevent by law the killing of birds for the sake of their plumage.

Up to 1901 there were only five States which had protective laws for birds otherwise than game, which were of a sufficiently stringent nature. During 1901 the following States placed laws on their statute books or added amendments to existing laws: Maine, New Hampshire, Vermont, Massachusetts, Connecticut, New York, New Jersey, Delaware, Florida, Wisconsin, Wyoming, and, in addition to these, the District of Columbia.

The law in the State of New York now covers all birds not game birds. Ten wardens are employed on the Maine coast, two in Massachusetts, one at Long Island Sound, while New Jersey, Maryland and Louisiana have wardens now.

Most of the wholesale houses, many of which belong to the wholesale Millinery Protective Association, will not deal in the plumage of any wild North-American birds.

If women would all coöperate in this good work by refusing to wear birds' feathers as trimming to dress or hats, a long step would be taken toward preventing the extermination of many species of wild birds.

More Public Baths for New York.

A sum of $105,000 has been appropriated by the City of New York for the construction of three public bath-houses, and it is said that the contracts for these buildings should be advertised for in August. It is planned that the baths shall be opened in July, 1903. A year should be ample time in which to finish the construction of the baths, although those in Rivington street took three years and seven months to complete.

The *Evening Post*, June 12, says that the projected baths in general will follow the plans suggested in the communication of the Association for Improving the Condition of the Poor. The buildings will occupy lots 50 by 100 feet. The basement will be devoted to boilers and machinery. The main floor has waiting-rooms for men and women next the entrance, each opening into a passage on which two rows of bath compartments face. On the second floor is a reserve section of bathing compartments which can be thrown open when needed in times of exceptional heat, or on holidays.

Floating-baths, of which there have been fourteen in New York, are to be decreased in number to seven, the Board of Health having condemned the others for sanitary reasons. Many physicians have declared at one time or another that these baths have been an important factor in spreading various contagious diseases, and Mr. Tucker made a report to this effect to the Tenement House Commission.

Unfortunately, too, there seem to be no more sites available for floating-baths, so that the necessity for permanent establishments for bathing purposes is greatly emphasized.

The Medical Record has always been an earnest advocate of plenteous bathing facilities for the poorer population of the city, and has seldom missed an opportunity to point out how far behind New York is in this respect to most cities of Europe.

Of course, however, the chief credit for bringing home to the inhabitants of New York their criminal carelessness in neglecting to provide an efficient bathing system is due to Dr. Simon Baruch. The erection of a number of fine bath-houses will be a monument to his persistent advocacy of the scheme.

The Mission of the Association of Military Surgeons.

The mission of the Association of Military Surgeons, aside from the consideration of purely professional subjects, was clearly outlined in the able address of the retiring president of the society, Lieut.-Col. J. V. R. Hoff, during its recent convention in the city of Washington. Col. Hoff urged that the organization, equipment and control of the medical departments of the State troops be made identical with those of the national forces, and that the influence of the society be directed to that end. He called attention to a mission of the Association in relation to the personnel and equipment of the national forces, in maintaining them in the highest possible state of efficiency. He showed the possibility, through the medical schools of the country, of providing for the dissemination of knowledge of military sanitation in the profession at large, so that every physician may be better prepared, in emergency, to undertake the work of a medical officer. A point emphasized by Col. Hoff was the necessity for the establishment of a national sanitary school for the education of those entering the medical services of the army and navy, and the Marine Hospital service. Such a school should be organized in Washington in connection with a great military hospital and training schools for hospital corps men and female nurses. To this sanitary school medical officers of the National Guard should also be sent for instruction. Finally he urged the presentation of plans by which private aid may be made to supplement, not supersede, the public services in time of war or other stress.

That there are vast opportunities for work by the Association along the lines indicated by Col. Hoff is apparent even to those not directly interested in medico-military affairs. The carrying out of the scheme proposed would greatly raise the standard of military medicine in this country, and do much to mitigate the horrors of future wars, and the enthusiasm with which these suggestions were received by the members of the Association augurs well for their execution in the early future. We particularly commend to the profession the suggestion that military hygiene be taught in the medical schools of the country, the need for such instruction having been abundantly demonstrated by the experiences of the Spanish-American war. For the teaching of this subject the services of army surgeons, on the active and retired lists, could in many cases be secured, and many surgeons of the National Guard would be glad to undertake work of this character. We believe that it will not be long before the leading medical colleges will appreciate the value of such a course of instruction and include it in their curriculums.

LOUIS PASTEUR.

In *McClure's Magazine*, June, is a well written appreciation of the late Louis Pasteur by Ida M. Tarbell. There is little doubt but that Pasteur was one of the greatest scientists who ever lived, and perhaps the greatest who has appeared within the past hundred years. All his discoveries were of direct use to the human race, either for the prevention or control of diseases or for the benefit of commerce.

Miss Tarbell recounts the three great truths he established:

Each fermentation is produced by the development of a special microbe.

Each infectious disease is produced by the development within the organism of a special microbe.

The microbe of an infectious disease, cultivated under certain detrimental conditions, is attenuated in its pathogenic activity; from a virus it has become a vaccine.

In 1883 the result of these discoveries were reported to the French Chamber of Deputies in the following words: "As a practical consequence of the first discovery, M. Pasteur has given rules for the manufacture of beer and of vinegar, and shown how beer and wine may be preserved against secondary fermentations which would turn them sour, bitter or slimy, and which render difficult their transport and even their preservation on the spot.

"As a practical consequence of the second discovery, M. Pasteur has given rules to be followed to preserve cattle from splenic fever contamination and silk worms from the diseases which decimated them. Surgeons, on the other hand, have succeeded, by means of the guidance it afforded, in effecting almost completely the disappearance of erysipelas and of the purulent infections which formerly brought about the death of so many patients after operations.

"As a practical consequence of the third discovery, M. Pasteur has given rules for, and indeed, has effected the preservation of horses, oxen, and sheep from the anthrax disease which every year kills in France about 20,000,000 francs' worth. Swine will also be preserved from the rouget disease which decimates them, and poultry from the cholera which makes such terrible havoc among them. Everything leads us to hope that rabies will also soon be conquered."

Rabies was conquered a few years later.

No more magnificent monument has ever been erected to any man than these marvelous discoveries are to the memory of Pasteur. His name is imperishable. In private life Pasteur was a modest, simple-minded man who never thought of his own aggrandizement, but was well content if he could do some good to his fellow men and to his country. In these days of self-advertisement such a type of man is rare and refreshing.

DEATHS BY POISON IN GREAT BRITAIN IN 1900.

The total number of deaths by poison in Great Britain in 1900, as shown by the sixty-third annual report of the registrar-general, exhibited an increase, being 1,193 as against 1,159 during 1899, or a net increase of 34.

The cause of death is classified in the following table: Accident and negligence, males, 472, females, 266; suicide, males, 276, females, 178; murder, 1, female.

The *British Pharmaceutical Journal*, commenting upon these figures, says that, while the accidental cases show a large increase, suicide by poison appears to have fallen somewhat into disfavor in 1900.

The 738 deaths due to accident and negligence in 1900, as against 636 in 1899, were mainly caused by substances which are not scheduled as poisons, only 160 appearing to have been caused by scheduled poisons.

Carbolic acid, which was not included in the schedule of poisons until September, 1900, was responsible during that year for 35 accidental deaths, 20 males and 15 females—a considerable reduction on the figures for 1899, when there were 45 accidental deaths due to carbolic acid. Mineral acids were accountable for 24 cases, accidental lead poisoning caused the death of 115 persons, while anesthetics used for operations, caused death in 116 cases.

Ptomaines, unripe fruit, etc., were the cause of 71 accidental deaths. With regard to suicidal cases, scheduled poisons caused 202 deaths, as against 252 by other toxic substances.

Carbolic acid was again the principal agent in cuasing death, being used in 134 suicidal cases; mineral and other acids were used in 51 cases.

It seems clear, says the writer in the *Pharmaceutical Journal*, that the inclusion of a poison in the schedule continues to prevent cases of accidental poisoning to a very large extent, and that the tendency to suicide is also checked in some degree. Thus scheduled poisons were the fatal agents in less than 22 per cent. of the accidental deaths during 1900, and in less than 44 per cent. of the total accidental cases and suicides.

News of the Week.

The Charles Rice Memorial Committee.—The Board of Trustees of the College of Pharmacy, in conjunction with the Committee of Revision of the U. S. Pharmacopœia, have appointed a committee to solicit funds for the purpose of placing a suitable monument over the unmarked grave of the late Dr. Charles Rice, and to defray the expenses of preparing a memorial volume, to contain his portrait and a sketch of his life and labors. Subscriptions to this fund are invited from all who appreciate the great work done by Dr. Rice, who sacrificed so much in the cause of medicine and pharmacy, and directed three decennial revisions of the U. S. Pharmacopœia. All contributions should be sent to Virgil Coblentz, 115 West Sixty-eighth street, New York City, or S. A. D. Sheppard, 1129 Washington street, Boston, Mass.

The Fight against Tuberculosis.—The Charity Organization Society of this City appointed, a few days ago, a committee consisting of eleven physicians and thirteen laymen to institute a crusade against consumption. The committee consists of the following: Drs. Herman M. Biggs, Joseph D. Bryant, J. H. Huddleston, E. G. Janeway, S. A. Knopf, T. Mitchell Prudden, Andrew H. Smith, E. L. Trudeau, Egbert Le Fevre, Henry Herbert, W. G. Thompson, and Ernst J. Lederle, Messrs. Homer Folks, F. H. Giddings, Charles F. Cox, Edward T. Devine, Eugene A. Philbin, Robert Hunter, Robert W. de Forest, Otto T. Barnard, and Herbert S. Brown, Mrs. James E. Newcomb, Mrs. Frederic S. Lee, Miss A. B. Jennings, Miss Ella Mabel Clark and Miss Lillian D. Wald. In addition to an investigation of the social aspects of tuberculosis the work of the committee has been outlined in part as follows: The promulgation of the doctrine that tuberculosis is a communicable, preventable and curable disease; the dissemination of knowledge concerning the means and methods to be adopted for the prevention of tuberculosis; the advancement of movements to provide special hospital, sanatorium and dispensary facilities for consumptive adults and scrofulous and tuberculous children among the poor; and the initiation and encouragement of measures which tend to prevent the development of scrofulous and other forms of tuberculous diseases.

Spreading Disease among British Army Mules.—A report is current in the sailor boarding-houses in New Orleans where the muleteers employed by the British during the South African war were recruited that some of the men who felt that they had been ill-treated by the British were employed by Boer agents to inoculate the horses, mules, and cattle with the virus of anthrax and glanders. If this report is true, but it probably is not, the Boer sympathizers have been hoist with their own petard, for the Boers in South Africa are now the greatest sufferers, as the diseases prevailing among the cattle and horses there will interfere very seriously with the restocking of farms in the Veldt by the British.

Association of American Medical Editors.—The annual meeting of this association was held at Saratoga on June 9 and 10, under the Presidency of Dr. Alexander J. Stone of St.Paul. Papers were read and addresses made by the president and by Drs. Charles H. Hughes, H. O. Marcy, Alonzo Garcelon, T. D. Crothers, Burnside Foster, D. J. McDonald, Jr., and I. N. Love, Dr. G. Frank Lydston sent a metrical contribution entitled "The Man behind the Krife."

New Public Baths.—It is announced that a large free bath-house will be built on Thirty-eighth street, near the east river, as soon as the buildings now on the land can be removed. The baths will be the gift of Mrs. A. A. Anderson, and will cost, with the land, about $100,000. They will probably be presented to the Society for Improving the Condition of the Poor.

Boycotting the Sick.—Among the news items relating to the strike of coal miners in Pennsylvania, published in the daily papers, is one stating that a band of fifty masked men, preceded by a drum corps, who were marching through the towns near Hazleton making demonstrations before the houses of non-union workmen, visited Dr. Stearns of Beaver Meadow and warned him under pain of severe punishment not to attend any of the sick or injured among the men at work in the mines.

Coronation Honors for Medical Men.—Among those upon whom coronation honors have been bestowed are Sir Francis Henry Laking, physician-in-ordinary to the King, and Sir Frederick Treves, sergeant-surgeon to the King, who performed the operation upon him, who have been created Baronets. Among those upon whom Knighthood has been conferred are Dr. Arthur Conan Doyle, the author, and Dr. William Selby Church, president of the Royal College of Physicians.

New French Hospital.—Plans have been filed with the Building Bureau for the new hospital which is to be erected for the French Benevolent Society on West Thirty-fourth street. It is to be of brick and Indiana limestone, 103.7½ feet front and 88.9 feet deep, seven stories front and six stories rear, and will cost $180,000.

New Hospital for the Aged of the Little Sisters of the Poor.—Plans have been filed with the Building Bureau in The Bronx for a new four-story and attic hospital and annexes to be built for the Little Sisters of the Poor on the plot covering the entire block bounded by Brook and St. Ann's avenues and 142d and 143d streets, opposite St. Joseph's Hospital for Consumptives. The hospital will be 318 feet long with two wings and will face 142d street. A chapel will occupy the 143d street wing, and a morgue, stable, laundry and other buildings will be provided, all connected by covered passageways with the main building. The buildings are to cost half a million dollars.

University of Pennsylvania.—A gift of $100,000 has been made as a memorial by an anonymous donor for the purposes of the building fund for the new medical laboratories. This sum is to be devoted to the pathological department.

Philadelphia Polyclinic.—Dr. Hilary M. Christian, surgeon in charge of the genitourinary dispensary of the University of Pennsylvania, has been elected Professor of Genitourniary Diseases at the Philadelphia Polyclinic.

Wills' Eye Hospital, Philadelphia.—Dr. Wm. Thomson has resigned as attending surgeon and has been elected consulting surgeon. Dr. Wm. Campbell Posey has been elected to fill the vacancy.

Training Ship "Dixie."—The Navy Department has decided to outfit the training ship *Dixie*, which recently carried the army relief expedition to Martinique, as a hospital ship and transport. In view of the contemplated mobilization into one great fleet, during the coming winter, of all the naval vessels on the Atlantic, South American and European stations, the presence of a hospital ship to care for the sick will be absolutely necessary. Many of the smaller vessels have absolutely no accommodations for the sick, and even on the largest hospital ships and transports these are very limited and quite insufficient to meet any special demands upon them.

Changes in the Medical Faculty of the University of Maryland.—Dr. L. McLane Tiffany, having resigned the chair of surgery in the University of Maryland faculty of physic, Dr. Randolph Winslow was on Friday elected Professor of Surgery. Dr. John Holmes Smith was elected Professor of Anatomy, Dr. D. M. R. Culbreth, Professor of Materia Medica, Dr. Frank Martin and Dr. St. Clair Spruill, Clinical Professors of Surgery, and Dr. Joseph W. Holland Demonstrator of Anatomy.

Smallpox in San Francisco.—In addition to the precautions taken at San Francisco against the embarkation on transports of troops unprotected against smallpox, orders have been issued at Manila that no troops from the United States will be allowed to land until vaccinated. The medical department will send a supply of vaccine virus on board each vessel as soon as it arrives and, if necessary, with medical officers to do the vaccinating.

Sick Troops in Manila.—During the month ending April 15 the percentage of sick to the total troops serving in the Philippines was 6.24 per cent. In the large Manila and department hospitals the percentage of total admissions was greatest for venereal diseases, 21.60 per cent., malarial fevers were 9.41 per cent., and dysentery was 9.94 per cent. Typhoid fever was 1.71 per cent. Out of a total of 36 deaths from disease during the month 18 were due to dysentery. There are at present 410 medical officers, 2,063 non-commissioned officers and privates of the Hospital Corps, and 56 female nurses on duty in the Philippines, having the medical care of 35,154 officers and men.

Major Walter Reed Honored.—At its recent commencement exercises, the degree of LL.D. was conferred by Harvard University upon Major Walter Reed, Surgeon U. S. Army, for his investigations resulting in an accurate knowledge of the way in which yellow fever is transmitted, and the methods by which it can be prevented or stamped out in a community. With General Wood, Major Reed was the guest of honor at a dinner given by a number of the prominent men of Boston to the army officers who were most concerned in bringing about the admirable results which characterized the reconstruction period of Cuban affairs while that island was under American control.

The Venice Incident.—The case of Surgeon Ledbetter, U. S. N., who, with other officers, was arrested and placed in confinement by the Italian officials for a disturbance which took place in Venice, while the U. S. S. *Chicago* was at that port, has been set aside by the admiral commanding the European station with the comment that, "while some or all of these actions may be considered indiscreet or lacking in dignity, none of them merit court martial, and none can be characterized as bringing scandal or disgrace on the naval service."

Cholera in the Philippines.—Reports from the Philippines state that the cholera problem there is great and very vexatious. With the exception of the small American and foreign population in Manila, the inhabitants are, to a man, antagonistic to the efforts of the Board of Health to eradicate the disease. This is particularly the case with the clergy and the merchant class. The business interests of Manila are consequently very much embarrassed, and a good deal of the shipping trade has been brought to a standstill.

The Martinique Relief Expedition—The Army medical officers sent with the relief expedition to the islands of Martinique and St. Vincent found little need for their professional services, as at Martinique nearly all those within the sphere of volcanic activity were killed outright, and the relief party did not reach St. Vincent from Martinique until after the injured had been well provided for by the local authorities. At Georgetown, St. Vincent, an improvised hospital contained about 400 patients who were suffering chiefly from burns. The medical supplies carried with the expedition were turned over to the French and English hospitals, upon whose resources the sudden emergency had caused a severe drain.

Vacancies in the Army Medical Corps.—Eighteen candidates have been found qualified by the Army Medical Examining Board, recently in session in Washington, out of the total of 129 authorized to appear for examination. The number of approved candidates is slightly in excess of the proportion usually found qualified by previous boards. The appointment of these candidates will leave forty-eight vacancies in the Army Medical Corps, with several additional vacancies in sight by reason of retirements for age, in the early future.

Cholera in Philippines.—To assist in coping with the cholera situation in the Philippines, fifty army surgeons have been detailed to serve on the board of health in Manila alone. The southern end of the island of Luzon is well infected. All army surgeons under orders to return to the United States are being held to special duty in the islands until their places can be filled under the Civil Government by civil surgeons.

Obituary Notes.—Dr. WYATT JOHNSTON of Montreal died on June 19. He was a graduate of the Medical Department of McGill University in the class of 1884, and had recently been appointed Professor of Hygiene there.

Dr. OBED LATHAM LUSK, deputy health inspector for the Borough of Queens under the former city administration, died at his home at Rockaway Beach on June 20, aged 42 years. Dr. Lusk was prominent in Democratic politics in Queens county, and for years previous to consolidation he served as health officer at Rockaway Beach and Far Rockaway. He was a graduate of the Chicago Medical College in 1882, and for some time served as surgeon in the United States Army. He was a nephew of the late Dr. Henry Palmer, founder of the Palmer Memorial Hospital in Chicago.

Dr. FREDERICK HORNER of Marshall, Va., died on June 15 as the result of a runaway accident. He was a graduate of the Medical Department of the University of Pennsylvania in 1851 and entered the navy that same year. He was retired with the rank of assistant surgeon in May, 1861, on account of incapacity for sea duty, and, with one exception, had been on the retired list of the navy longer than any other officer.

Dr. GEORGE F. CAREY died at his home in this city on June 16, at the age of sixty-six years. He was born in Ireland, and when about sixteen years old came to this country and has resided ever since in this city. He was a graduate of the College of Physicians and Surgeons in the class of 1874.

Dr. J. F. MEYER of Buffalo was accidentally shot and killed on June 20. He was a graduate of the Medical Department of Niagara University in the class of 1891.

Dr. AGNES B. ROBINSON MESSNER, a daughter of the late Dr. Chas. M. Robinson, died at Philadelphia on June 5. She was graduated from the Woman's Medical College in 1894, and was Assistant Demonstrator of Anatomy in the college.

Correspondence.

OUR LONDON LETTER.

(From Our Special Correspondent.)

MEDICAL COUNCIL—SAMARITAN HOSPITAL—ADDISON'S PERNICIOUS ANÆMIA—HANOTS' CIRRHOSIS—SOCIETIES.

London, May 30, 1902.

The General Medical Council met on Tuesday, when Sir Wm. Turner, K.C.B., opened the proceedings with his usual presidential address. He said no progress had been made in Parliament with the bill prepared by the council. He regretted that the business of a penal and disciplinary character to be settled was more than usually heavy, chiefly on account of convictions in the criminal courts which had been reported. Two new cases in which serious breaks of professional conduct were alleged to have been committed must also be investigated. It was gratifying that no charges of covering, nor of association with "medical aid societies," were to be considered. The council has been requested by the Privy Council to send a delegate to the Brussels Congress on the subject of an international pharmacopœia of limited extent.

A communication from the British Medical Association asking the council to receive a deputation on preliminary education was read. One or two members thought the proposal savored of a censure on the educational committee, but others did not see any intention of the kind, and after some conversation it was agreed that the deputation should be received by the Committee on Education. As to this, I may remark that the deputation will have to submit the report of the association, which is to the effect that every practitioner should receive such a preliminary education as should entitle him to be regarded as a member of a liberal profession.

With regard to the penal cases, it seems more desirable that the council should get their powers amended so as to be able to deal with them more expeditiously, as well as more economically. Surely it is a *reductio ad absurdum* for distinguished representatives of universities and colleges to be brought together, at great expense, to solemnly judge whether a man convicted of felony should remain on the roll. One would suppose that such conviction should automatically exclude him. Even if an appeal on the point be considered advisable, it is a wicked waste of brains and money to gather thirty of the most distinguished men to decide whether a criminal conviction renders an individual unworthy of a place on the register of the profession. A court-martial *ad hoc* can decide if a military man has been "guilty of conduct unbecoming an officer and a gentleman." Some such court-medical might be entrusted to decide on professional matters.

There is just now an unprecedented scandal as to hospital government which might well be submitted to such a tribunal. As it is exciting much attention, and yet its true inwardness has not been exposed by our journals, I will give you details which will suggest, I think, that though the committee is taking the blame so far as to offer a feeble apology, the action of the staff calls for enquiry as to whether it has been becoming to doctors and gentlemen.

This extraordinary case is one of an election to and subsequent removal from a hospital post. In September, 1900, a vacancy in the post of physician to out-patients at the Samaritan Free Hospital for Women and Children was advertised, without any sort of notification that the appointment, when made, would be subject to confirmation a month afterward. Dr. J. A. Shaw-Mackenzie applied for the post, with others. The committee proceeded to elect him, notified him and the medical directory of his election, and accepted his services for some weeks without telling him the appointment was provisional. A month later the secretary of the hospital wrote that the minute referring to his election was not confirmed, and the medical secretary wrote that, as the appointment was not confirmed, it would be unnecessary for Dr. Shaw-Mackenzie to attend in the out-patient department or at operations. Subsequently, the secretary of the hospital wrote that the post was vacant; that the committee had resolved to take up the election again at the point of the reception of the medical committee's report on October 23, 1900, and, to cut the matter short, another candidate was appointed. The committee then allowed more than a year to go by before making the tardy explanation that there was no shortcoming on Dr. Shaw-Mackenzie's part. As now admitted in a letter published in the *Lancet*, May 10, from the secretary of the hospital to Dr. Shaw-Mackenzie, the committee state that his non-election permanently was not attributable to any fault or shortcoming on his part; that he gave his valuable service to the hospital for some weeks, and the committee had no reason whatever for dissatisfaction, and they go on to express regret that the letters notifying his appointment to him and the medical directory omitted to state that it was provisional only. As far as can be ascertained, it seems that the medical committee recommended another candidate, and did not recommend or vote for Dr. Shaw-Mackenzie. The committee, however, recognizing his claims, added his name, and the voting proved equal. Under these circumstances the chairman did not give a casting vote; the election was postponed for the purpose of making further enquiries respecting the candidates, and at the next meeting Dr. Shaw-Mackenzie was elected, two of the consulting staff voting for him. A month later the medical committee met and passed a resolution protesting against their recommendation for the post being ignored by the committee of management. Dr. Shaw-Mackenzie was present at this meeting as an acknowledged member of the staff, and did not vote for this resolution. The following date the procedure of the election was questioned, and the appointment not confirmed. Finally, Dr. Shaw-Mackenzie felt compelled to bring an action against the committee, and ultimately accepted the letter of explanation and regret. It is an extraordinary thing that the committee did not from the first recognize the necessity of making it perfectly clear that no blame attached to Dr. Shaw-Mackenzie. Apart from the merely personal aspect of the case, no hospital ought to have a rule under which physicians are asked to give their services for a month on approval, and if they have such a rule, the least they can do is to publish it when advertising for candidates. It is outrageous that a man's good name and reputation should be exposed to the accident of a vote, or to the rallying of supporters of another candidate, and that he should be involved in litigation through a mistake of the committee, or the claim of a staff to control the elections. The case is, fortunately, unparalleled in the annals of hospital government.

Dr. Wm. Hunter has brought his view of pernicious anæmia before the Pathological Society in a paper illustrated by lantern slides, specimens, and cultures. This paper may be described as a development of his former contributions to the subject; it was based on twenty-five cases observed during the last two years, with seven necropsies.

The thoroughness of the investigation may be seen by one or two points. Thus, in the seven necropsies histological examination was made of the whole digestive tract from the tongue downward, and control observations of the same tract in twelve other diseases characterized by oral sepsis. In this work 100 pieces of tissue were cut, and the number of sections stained and examined for organisms, 1,145, besides which 250 cultures were made. In all the twenty-five cases the peculiar form of glossitis previously described by Dr. Hunter had been found. There was great thinning of the mucosa, which, in some places, was quite wanting, so that the lymphatics of the tongue were in continuity with the buccal cavity. From these lymphatics he obtained pure cultures of streptococcus longus, which killed mice in six or seven days. The same organism was obtained from the mucoid vomit which occurs in the disease. There is then, according to Dr. Hunter, a specific infection, of which the chief evidence during life is a glossitis, easily overlooked—a septic infection of the mouth and whole elementary canal. The vomit and other symptoms during life point to gastritis and further intestinal complication, and after death these are explained by the gastritis, gastric atrophy, intestinal atrophy, erosions or ulcers now and again found.

Clinically, all the twenty-five cases conformed closely to Addison's original account of anæmia "without discoverable cause," all might have been described in Addison's own words. Dr. Hunter therefore does not include many cases which Ehrlich and other German physicians group with pernicious anæmia, but separates those in which oral sepsis is associated with the symptoms described by Addison, and which he has termed septic anæmia, and might also be called Addison's pernicious anæmia.

Sir T. Barlow and Dr. Batty Shaw showed two cases at the Clinical Society to illustrate the inheritance of recurrent attacks of jaundice and abdominal crises with hepatosplenomegaly, such as have been described by Dr. Claude Wilson as occurring in three generations, and by Dr. Finlayson, as affecting collaterals. The patients were a mother, aged forty-seven, and son aged nineteen and a half. The latter had been delicate from birth. At five he was jaundiced for the first time, and since then has had attacks of "semi-jaundice," with pain in the upper part of the abdomen. These attacks last three or four days. For the last six years he has had indolent ulcers about the ankles, which only heal after some days in bed. There is slight enlargement of the liver and much more of the spleen; a reduction of red corpuscles, and hæmoglobin, etc. Brothers and sisters are not affected, but one brother had one attack of jaundice in childhood. The mother's history is similar. Her first attack was at five. She had one when pregnant. Both patients have always lived in England.

The paper suggested that the mother's was a case of Hanot's cirrhosis of the liver and the son's an earlier, incomplete stage of the same. Attention was called to the greenish pigmentation of the skin in each case. The mother has grown up with the disease, had a large family, and except for these attacks has enjoyed fair health. Two of the cases described by Dr. Wilson, having been lately seen by one of the authors of the paper, were found pretty well.

Dr. Rolleston regarded the cases as intermediate between acholuric jaundice and Hanot's biliary cirrhosis in adults. He said the symptoms of both diseases had been observed in some families, and French observers had mentioned cases of Hanot's disease with splenic enlargement.

Dr. H. French insisted on the occurrence of hemorrhages as a chief feature of splenic anemia.

The smallpox admissions this week have varied from thirty-two to fifty per day.

The Royal Society is sending a commission to Uganda to investigate sleeping sickness.

Lord Lister has been elected President of the Pathological Society, if, on his return, he is willing to accept the post. Mr. Howard Marsh will continue President of the Clinical Society for another year. The Medical Society's conversazione was held on Monday, when Dr. S. Mackenzie delivered the annual oration.

The Medical Temperance Association's twenty-sixth annual meeting was held on the 20th ult. Professor Sims Woodhead presided.

THE INFLUENCE OF PROLAPSE OF THE KIDNEY ON THE PRODUCTION OF PELVIC DISEASES IN THE FEMALE

To the Editor of the Medical Record

Sir: Permit me to call attention to some inaccuracies that occur on page 1016 of the report of the proceedings of the section on Diseases of Women of the American Medical Association at Saratoga. I claimed that prolapse of the kidney by compressing the ovarian vein retards the return circulation from the pelvis and produces pelvic congestion with its attending evils, and is therefore a cause of pelvic disease, that even in the early stages of prolapse the lower pole of the kidney often overlaps the ovarian vein and ureter, and when the abdomen is compressed by corsets or clothing the kidney is crowded backward and compresses the ovarian vein and ureter between it and the solid structures of the back.

Prolapse of the kidney by traction on the vessels of the pedicle gives rise to congestion and by torsion or flexure of the ureter causes obstruction, hence it often leads to structural disease of the organ which is lost sight of in dealing with this condition.

Artificial supports, I considered objectionable in advanced degrees of prolapse, where they would be most needed, because they are a source of irritation to the kidney, but no contention was made that they caused increased flow of urine.

In closing the discussion that followed, I maintained that the constitutional disturbances were rather the result than a cause of prolapse of the kidney, and that I believed the failure to relieve symptoms by the operation for fixing the kidney was due to too late operation, or to the kidney being fixed too low, or to failure to secure permanent fixation.

A. H. Goelet, M.D.

LETTER FROM CONSTANTINOPLE

THE WEATHER CONDITIONS—DR. RIEDER'S RESUMPTION OF WORK—QUARANTINE AGAINST MECCA PILGRIMS AND AGAINST EGYPT—SYPHILIS IN ASIA MINOR—ALLEGED MIRACULOUS CURES.

(From Our Regular Correspondent.)

Constantinople, May 24, 1902.

Constantinople has an atmosphere rather than a climate. Situated on a hill between two seas, it is at all times subjected to great variations of temperature. But this season is a record one in the way of temperature. The alternations of heat and cold have been very frequent and irregular, trying even to strong people. Consequently there have been many cases of bronchitis, pneumonia, catarrhal sore throats and gastric affections. There have however been fewer cases of pure typhoid, which may reasonably be attributed to a certain degree of improvement in the municipal health regulations, though there is yet much to be desired in these respects. Plague in Egypt and cholera at Mecca act as municipal stimulants.

The medical classes at the Gulhané School of Medicine were opened at the usual season. This school is directed by Dr. Rieder Pacha, who has completely recovered from the injuries he sustained last year. The German Ambassador and Ambassadress were present to express to Dr. Rieder Pacha the satisfaction of the Emperor William at his recovery, due to the intelligent care bestowed on him by the medical staff and four German nurses. His Excellency then bestowed various decorations of the Red Eagle and Crown of Prussia on Drs. Deike Bey and Hoffmann and the Turkish doctors of the school. A special operator for the school and hospital has since been engaged—a Dr. Dicke of Hamburg.

Quarantine against Egypt is always more or less in force on account of the recurrence of plague cases. The presence of cholera at Mecca and the return of the pilgrims have necessarily added to the quarantine restrictions, but it is to the credit of the sanitary authorities that they have been made as little vexatious to commerce and travellers as possible. Up to April 2 7,316 pilgrims had quitted Djeddah to return to their countries. Of these 2,172 will arrive at Constantinople. Measures were taken to prevent overcrowding of hans and hotels by these pilgrims of Bokhara and the Caucasus obliged to disembark. Russian pilgrims returning from the Hedjaz after having "purged" quarantine at Thor on the Red Sea will be required to pass through the Bosphorus in quarantine (*en contumace*) on their way to Russia. In case, however, of plague or cholera occurring on board, these ships and pilgrims will undergo the reglementary quarantine at the lazaret of Clasamene, and afterward pass through the Bosphorus *toujours en contumace*.

The latest regulations are of May 20: "From Egypt via Piræus, 48 hours' quarantine with disinfection of clothes and goods at the lazaret of Clasamèns, but ships from Piræus having a bill of health (*patente de Santé*) with the Turkish consular vise attesting that they came from Egypt, but have remained at Piræus five days before embarkment, will be received in free pratique." This may be changed to-morrow if further cases of plague occur. Plague is now endemic in Egypt, and sporadic cases will arise for a long time to come. This prospect, then, of a continuous and fluctuating quarantine against that country is considered with great anxiety by the shipping interests affected.

On the subject of quarantine there has been an interchange of views and opinions in the columns of the *Medico-Therapeutical Review* of Constantinople, in which several of the professed sanitarians have taken part. The old arguments pro and con have been again thrashed out, some advocating the entire suppression as a thing out of of date and having no scientific basis; others, the majority, being in favor of it, though in a modified form, and in accordance with the principles of advanced sanitation. Nearly all, however, declared land and frontier quarantine as being useless.

The CO_2 process of Mr. Pierre Apery for killing rats on board ship is still a fertile subject of discussion in the local press and scientific societies here, and has given occasion for various utterances, and not altogether polite recriminations. Microbes, rats, and the little things upon them, are responsible for a passage of arms between Prof. Remlinger of the Bacteriological Institute and Mr. Apery, which has extended to the Belgian medical journal, *Le Médecin*.

For some years past the attention of the Imperial Government has been directed to an important subject, *i.e.*, the spread of syphilis in many of the provinces of Asia Minor. Dr. von During Pacha was sent on a mission to these provinces to examine, report upon, and suggest measures to arrest the ravages of this malady. It would appear from his investigations that syphilis was spreading to an alarming extent, and, new local hospitals are being established in the districts most affected under the direction and supervision of Van During Pacha, who, needless to say, has a European reputation as a dermatological specialist.

How such increase of this disease in districts formerly known to be relatively free from it can be explained is an interesting question. It has been suggested that it was introduced in a more virulent form by returned troops after the Russo-Turkish war. This is a feasible explanation, and it is evident that the unsanitary state of the interior and surrounding unhygienic conditions would favor the development and increase the virulence of the disease once introduced. It will be no easy task to combat. So far as the male population is concerned, much can be accomplished by the measures already taken, but with the female it will not be so easy, as there are greater difficulties in the way—religious and social.

The saints of the Greek Church are competing against legitimate medical practice. The columns of two Greek journals are filled with the description of imiraculous cures performed by the image of the "Panagia," or Holy Virgin, in the Church of the Virgin at Alte-Memer. According to the papers, the wonderful cures are authenticated by certain persons of the Greek community, who announced to the Patriarchate the cure of a young girl dumb from her birth. This and other miraculous cures caused such an enormous affluence to the Orthodox Greek Church of Alte-Memer that the Grand Vicar was authorized by the Patriarchate to declare to faithful Christians that there was no foundation for those reports of the local press, and that the said person, or persons, had not made any such representations. In spite of this declaration the crowds still pressed daily at the church, as the reports of further miraculous cures spread in the city. Finally the Patriarchate issued a third declaration "that the Church was not convinced of the authenticity of what was stated to have occurred at Alte-Memer, and that the Alte-Memer Church would not be opened except at the usual hours of morning and evening prayers, and that these prayers would be followed by two adorations before the image of the Virgin, which would be maintained in its usual place, and no one permitted to touch it, and that collections of money were strictly forbidden." The "Eikon" is credited with certain muscular powers of conviction. The multitude, however, maintain there is something in it, as it cannot be all lies.

DENTISTS NEEDED IN HOSPITALS.

To the Editor of the Medical Record:

Sir: The need for the regular attachment of one or more qualified dentists to the staffs of every hospital and dispensary seeking to aid humanity by attention to the practices of preventive medicine cannot be overlooked.

In the rush to be the first to find the "knock-out drops" fitted to match with the latest discovered microbe, or lost in the brilliancy of an active operative surgical career, the physician of our day is too prone to forget that back of every disease which is presented to him is an individual, and nowhere is this oversight so manifest as in the wards of hospitals and in dispensaries. Owing to the press of numbers of patients coming before him the visiting physician easily engrafts a habit of superficiality or too great dependence upon his assistants, and many failures of success on the part of the average medical man may be traced to habits of negligence learned in an institution.

If an interne or a nurse dosed a patient under his or her charge with the contents of culture tubes from the laboratory, their stay in the house would be short, and, in the light of our times, a trial upon a criminal charge might be remotely possible, yet every day patients lying in the wards or receiving medical treatment in one form or another in the out-patient departments of our hospitals are allowed to swallow the diversified colonies of bacteria constantly present in their mouths without any attempt at prevention upon the part of their medical advisers. Aside from being centers of propagation for mouth contamination, decayed teeth, by interference with proper mastication of food and so affecting the nutritive processes, open the way to future ill-health. The late Dr. William Pepper was so impressed with the importance of this factor in disease that he made it his practice to refuse a patient, whether he was private or free, having bad teeth until the defect was remedied.

By a study of the oral cavity of the average walking dispensary patient an idea of the condition of the public mouth is readily gained, and the need for education in the use of a tooth-brush is demonstrated. The triumphs of American dentistry are known the world around. By appointing a sufficient number of dentists to attend to the needs of its patients the medical board of a hospital will demonstrate a spirit of progress befitting to our times.

Frederic Griffith, M.D.

805 Madison Avenue.

APPENDICITIS INCISIONS.

To the Editor of the Medical Record:

Sir: The interesting contribution on the subject of appendicitis incisions by Dr. Wyeth in the Medical Record for June 7, 1902, will probably meet with the approval of the majority of surgeons, and yet it seems to me that we can save more time for the patient, and at the same time avoid unnecessary scarring by employing shorter incisions than the one that he advocates. In interval cases, and in cases before the advent of abscess formation, an incision one inch and a half long, through skin, muscle and peritoneum, is sufficient, in routine work. I depend upon this length of incision, and make it a rule to allow the patients to get out of bed on the seventh day after operation, and to return to their ordinary occupations on the tenth day. I have employed the gridiron dissection advocated by McBurney ever since the publication of the first article upon the subject by that distinguished author, and this, in connection with the short incision, gives the patient a great advantage. One hears a good deal about the difficulty of separating adhesions through the short incision, but that belongs to beginners, and it is rarely, indeed, that one will find adhesions requiring work by sight. As to the dangers of the short incision, my patients are all alive, or were at the time of their discharge, and that ought to be sufficient answer. There have been only two hernias to my knowledge after the inch-and-a-half incision. One of these was in a case of tuberculosis of the appendix, and was repaired by Dr. Coley. The other one is in a case in Iowa, in which abscess of the abdominal wall formed after operation. It is a small fixed hernia, and the patient does not care to have anything done for it. If there are any other cases of hernia I shall be very glad to know about them, as I do not care to deceive myself nor any one else in this matter.

In cases with abscess, or widespread peritoneal infection, I use an incision about three inches long, and employ here also the gridiron dissection, rarely cutting across the belly of a muscle, and seldom finding it necessary to use retractors. The muscles fall together after operation, with the aid of a very little suturing, and there are no hernias to my knowledge in any of my cases since the gridiron incision was adopted. The long-incision patients remain in bed for an average length of seventeen days. None of my patients are advised to wear a supporter after abdominal operations of any sort. Sometimes their physicians like to put them on, and it may be that there are some cases in which the patient obtains comfort for a while from the use of a supporter, but my belief is that proper suturing, and the avoidance of the employment of gauze packing practically does away with the need for supporters. Experience in every day practice, and the result of experiments with rabbits (See page 129, "Lectures on Appendicitis") apparently give sufficient testimony bearing upon this point.

Robert T. Morris, M.D.

58 West Fifty-sixth Street, New York, June 7, 1902

CHLOROFORMING A SLEEPER.

To the Editor of the Medical Record:

Sir: I have noticed several remarks about it being impossible to administer chloroform to a patient without awakening the patient, especially a letter in the Medical Record of March 29. Any person who has at all administered chloroform often, will have been at times asked to do so to children that are asleep. It is quite possible to administer chloroform, not ether, to children when they are asleep, and I have given it that way myself many times without wakening the child, giving it in the bed and carrying the child to the table after being under the chloroform. It is easily accomplished by placing a drop or two to start with on an open wire mask with a layer of gauze over it. I think this question has come before the profession often enough to have been settled by this time.

H. A. Stevenson, M.D.

London, Ontario.

Professor McWeeney of Dublin on the Milk Question.—Professor McWeeney, at a recent meeting of the Royal Academy of Medicine in Ireland, said that codification of the sanitary laws was a necessity; as things were, a whole library of legal books was wanted to find out the law of sanitation. Sterilization of milk was out of the question; it made ordinary milk unsightly and unpalatable and spores resisted boiling for three hours under a pressure of two atmospheres. Pasteurization killed typhoid germs at a temperature of 140° F, and at 190° it killed the tubercle bacilli; no creamery should be allowed to vend milk until it had been properly pasteurized. As for the Dublin dairy-yards, he considered them to be a disgrace to civilization; they were kept in an intolerably filthy state, and, as for the attendants he thought that if they had the German sanitary law in force in Dublin, some 90 per cent. of the milkers would be arrested and forcibly washed. There could be no proper supervision of dairies without a bacteriologist; a veterinarian could not make an exhaustive microscopical examination of milk or perform the necessary biological experiments.

Progress of Medical Science.

The [illegible] Medical and Surgical Journal, June [illegible]

The Use of Suprarenal Extract in Hay Fever.—[illegible]

Report of a Case of Chronic Continuous Hypersecretion with Hyperchlorhydria (Reichmann's Disease), with Especial Reference to Treatment.—[illegible] Hypersecretion followed the consumption of food by the mouth, but the gastralgia was stopped by the rectal feeding and is now prevented by lavage, attention to diet, and occasional fasts of from twenty-four to thirty hours. An absolute cure has not been obtained, but much has been done for the patient. He has had placed in his hands the means by which he can protect himself from the intolerable gastralgia. He has been enabled to follow his occupation continuously for the past ten months, whereas previously he was losing one-sixth to one-fourth of his time. The state of dejection and despair, in which he affirmed he did not care to live if he were always to have the pain, has been replaced by one of comparative comfort and happiness.

Journal of the American Medical Association, June 21, 1902.

Gangrene Following Thrombosis of the Abdominal Aorta and Its Branches.—The case is reported by R. E. Garrett, his patient being an insane woman, aged thirty-four years. Acute symptoms commenced with irritability and pain in the legs, with inability to stand and walk. Slight fever was present. The next day cardiac failure was noticed with profound syncope, quickly passing to a condition of semi-coma continuing for several hours, after which the general condition improved. A few days later dry gangrene appeared in one toe of the right foot, soon involving the entire member. Amputation was done at the junction of the upper and middle thirds of the right thigh. Healing was uneventful. The left foot was somewhat cold, but up to time of record, thirty-seven days after the onset of symptoms, remained intact. The dissection of the amputated part showed the femoral and popliteal arteries to be occluded by a firm, hard thrombus, extending in one continuous clot from the point of incision in the femoral down through the popliteal to within about an inch of where the anterior tibial is given off. The veins were normal. The author is unable to decide whether the case was a traumatic one due to some self-inflicted injury or accident, or whether it was due to spontaneous coagulation, such as has followed certain febrile conditions, including influenza.

Analysis of Ninety-six Operations for the Relief of Tuberculosis of the Testis.—The conclusions offered by Orville Horwitz, are as follows: (1) A primary tuberculous infection of either the epididymis or testicle may occur, the former being by far the more common; (2) A primary infection of the epididymis, secondarily that of the testicle, is more common than the descending one. (3) Primary involvement of either the epididymis or testicle usually takes place through the circulation, the soil being predisposed to the location of the tubercle bacillus, either by a slight traumatism or by some reflective condition which has given rise to inflammation of the organ, most commonly an attack of gonorrhœa. (4) Secondary tuberculous involvement of the epididymis or testicle sometimes follows a primary focus of the disease in other portions of the body, more commonly in those organs that are in a direct anatomic connection with the sexual glands, such as the seminal vesicles, prostate, urethra, bladder, ureter, or kidney. (5) The invasion of the testicle may be rapid, associated with acute inflammatory symptoms, an abscess soon developing, or the onset may be slow, the symptoms simulating those of either chronic syphilitic orchitis, or malignant disease of the organ; (6) The tuberculin test should always be employed in doubtful cases when only one focus of the disease is known to exist, (7) In doubtful cases associated with hydrocele the fluid should be examined for [illegible] (14) Whether [illegible] From the fact that in a large majority of cases the removal of the primary focus of the disease is followed by a subsidence of the tuberculous involvement of the vesicles, it is deemed wise, as a rule, to wait and remove the vesicles later, if necessary. (15) Hygienic and climatic influences play an important part, after operation, in fortifying the constitution against further invasion as they do in other tuberculous conditions.

New York Medical Journal, June 14, 1902.

Two Cases of Supposed Gastric Perforation in Which No Explanation of the Symptoms Was Found at Operation.—The cases are reported by Andrew H. Smith. The first case was that of a young woman aged twenty-eight years. Her symptoms were gastric pain and tenderness with great acceleration of the pulse and a grave condition of shock. The abdomen was opened, but the peritoneal cavity appeared normal. The exterior of the stomach showed no changes. It was, therefore, not opened. Death followed in twenty-four hours. No autopsy was allowed. The occurrence of hemorrhage was excluded by the absence of blood from the material last vomited and from the condition of the stomach at operation. The second case was that of a married woman, aged twenty-eight years, with the usual history obtainable in cases of gastric ulcer. Symptoms of perforation finally developed and a laparotomy was done. On opening the abdomen no free fluid or adhesions were found. The stomach was distended with gas, and contained a little brownish fluid, possibly disintegrated blood. The mucous membrane was greatly congested, and in the lesser curvature was found an ulcer of the size and shape of a melon seed, which, however, extended only through the epithelial layer, and showed no signs of recent hemorrhage. The edges of the ulcer were soft and not elevated. The ulcer was excised and the stomach well sutured to the wall of the abdomen. Saline infusion was resorted to, but death occurred in twenty-four hours. Autopsy showed fatty degeneration of the liver, otherwise no gross lesion of any organ other than stomach. Microscopical examination of the mucous membrane of the stomach showed tubercles, and two or three tubercle bacilli were found.

New York Medical Journal, June 21, 1902.

Difficulties in the Diagnosis of Certain Febrile Diseases.—Glentworth Butler gives the clinical histories of ten cases, with comments on each. By adding a number of similar cases of which some record has been kept and collating them with reference to their pathological character, he divides them into four groups, viz., those in which the febrile symptoms were due to (1) Concealed suppuration; (2) Tuberculous infection, (3) Irregular typhoid, and (4) Malignant endocarditis. All of these diseases should be borne in mind when we are in the presence of febrile symptoms of obscure origin.

Gastroptosis the Cause of Symptoms Erroneously Attributed to Nephroptosis.—According to Achilles Rose, gastroptosis and nephroptosis form part of enteroptosis. It is doubtful whether displacement of the stomach or kidney ever exists without the whole splanchnon being more or less relaxed. Gastroptosis is oftener overlooked than diagnosticated. Rose comments on the great confusion existing in literature as to the exact signification of the above terms and claims that the relief of the general enteroptosis will often remove the symptoms of floating kidney, the latter being but a part of the former general condition. He believes that many operations done for floating kidney are unnecessary. Enteroptosis marks certain symptoms which are relieved when the causal condition is relieved. Nephroptosis is included in enteroptosis and it is impossible to see how the displaced kidney can be accused of causing the symptoms attributed to it exclusively.

American Medicine, June 21, 1902.

The Evaporation Bath in Typhoid Fever.—J. Morgan Coffin describes the technic of this bath, as follows: The patient is first placed on a blanket, then a layer of one thickness of absorbent gauze is fitted closely to the body surface. This is sprinkled with water at a temperature of 100°–112°F. An electric fan, situated at the foot of the bed, on a level with the patient's body, furnishes the change of air necessary to dry the gauze. The average length of time required to evaporate one pint of water was thirty minutes. In all the cases of typhoid fever (100+) treated in the hospital by the writer during a period of three months, those treated by the evaporation bath method gave the least satisfactory results, as compared with tubs or sponges, and their course was almost identical with a series of cases in which no hydrotherapy was used. The baths were distasteful to the patients, and in addition the entire ward was disturbed by the constant buzzing of electric fans. There was practically no response except in temperature, the effect on the circulatory and nervous systems being nil. And, although the series is somewhat short for comparison, it may be noted that the mortality in the evaporation-bath series was $13\frac{2}{3}$ per cent. as compared with $10\frac{5}{7}$ per cent in all other typhoid cases during the same period.

The Relation of the Caliber of the Urethra, and Especially of the Meatus Urinarius, to Vesical Tone.—G. Frank Lydston concludes that: (1) The normal vesical tonus depends upon a certain degree of physiologic obstruction to the urinary outflow; (2) The structural and functional integrity of the vesical walls depends upon this same resistance; (3) The resistance is normally most marked at the meatus, although the entire urethra is a factor in its production; (4) This resistance is both elastic and inelastic at different points in the urethra, and in varying conditions (5) An exaggeration of this resistance produces atony of the bladder in old subjects, hypertrophy and exaggerated power in the young. Exceptionally, it produces atony in the young, but, as a rule, only as a reflex neurosis; (6) A marked diminution of this resistance, such as results from urethrotomy, and especially meatotomy, produces vesical atony of greater or less degree; (7) The foregoing should be borne in mind by the surgeon, and, in certain cases, the resistance of the meatus preserved by careful operative technic; (8) In most cases the resulting atony is of little moment, but it is always worthy of consideration, and in some cases of sufficient prominence to be worthy of serious attention; (9) In cases in which a free urethrotomy has been performed, it is wise to instruct the patient to compress the meatus somewhat during micturition, so as to maintain the normal vesical tonus by offering sufficient resistance to the outflowing urine to properly exercise the vesical muscle.

Medical News, June 21, 1902.

Neurectomy for Facial Neuralgia.—E. M. Magruder says that facial neuralgia is probably one of the most obstinate of the non-fatal affections with which the physician has to deal. The pathology is doubtful, as parts of excised neuralgic nerves in certain cases appear to be perfectly normal, while in other cases they present pathological changes. As to the surgical treatment of this affection, the writer notes three methods: (1) Division of the nerve-trunk or branch that gives pain; th relief from this measure is very short, as function is soon reestablished; (2) Excision of the Gasserian ganglion; the writer has had no personal experience with this method; (3) Excision of a part of the offending nerve; the results with this method have been varied. The author gives the history of several cases. One of these was a man seventy-one years old, upon whom he operated eleven times in less than nine years. The right supraorbital region was the seat of operation four times, the right infraorbital region ten times, the right nasal nerve, once, and the right temporal region once. All these operations gave more or less temporary relief, varying from four to eighteen months—in the earlier ones perfect relief and in the later ones only an amelioration of symptoms. On several occasions directly after some of the later operations, the pain seemed to increase to an extreme degree, then it would diminish, but not entirely disappear. The disfigurement was very slight after the first two operations in any one place, but increased with each subsequent operation and finally became quite marked.

Philadelphia Medical Journal, June 21, 1902.

Report of Five Cases of Asthma Treated with Silver Nitrate Injections.—H. T. Bass describes this method of treatment, which he learned from Thomas J. Mays. Five drops of a 2½ per cent. solution of silver nitrate are injected in the neck under the skin over the vagus nerve, a little to the outer side of the carotid artery—about midway between the angle of the jaw and the clavicle. Two of the five cases which he has treated in this way are relieved up to this time; another case up to the first of December, and this case is now under treatment; while two others seemed to be relieved somewhat while under the active treatment. The writer states that Dr. Mays is very hopeful for the treatment in asthma, and is enthusiastic over silver nitrate injection in the neck in phthisis.

Fourteen Cases of Spastic Spinal Paralysis Occurring in One Family.—William G. Spiller makes this interesting report. He presents a table showing the occurrence of this disease in fourteen individuals in one family. He describes two of the cases. Both of these patients are very intelligent. In both of these cases the symptoms are merely spastic paresis of the lower limbs with contractures and exaggerated reflexes of these limbs. Of late years the disease is said to have commenced before or about the fifth year of life, and has always presented the same symptoms. It is almost as common in the female sex as in the male. The older of these two cases described began to show the symptoms at about five years of ago. The lower limbs are not atrophied. The left foot is in equinovarus position, while the right foot is much less contractured. The left foot is shorter than the right and the instep is high. There is little voluntary movement of the toes and feet, and the weakness is greater on the left side. Sensation for touch and pain is normal everywhere. The knee jerks are much exaggerated. Ankle clonus and the Babinski reflex are distinct on each side. The feet are tender in walking. The gait is very spastic. In walking, the right foot turns inward, but in sitting it is straight. The muscles all respond to the faradic current, but a strong current is required. The muscles of the upper limbs are well developed and the patient has a powerful grasp of the hand.

The Lancet, June 7, 1902.

Dilatation of the Heart and other Manifestations of Weakening of the Heart as Results of Rheumatism.—T. Fisher notes that the rheumatic poison often causes dilatation of the heart and passes over the valves. In most people the fibrous pericardium does not fit the heart so closely that there is not sufficient space for considerable dilatation of the heart and the dilatation that occurs during rheumatic pericarditis is not due simply to the weakening of the fibrous pericardium but to the direct influence of the disease toxins on the heart muscle. Dilatation may be followed by hypertrophy, independent of any adhesions or valvular defect. If a poison such as alcohol can produce enlargement of the heart it does not seem unreasonable to suppose that the toxins of rheumatism may do so also. This appears especially probable when it is remembered that rheumatism affects the heart most seriously while that organ is growing. Marked enlargement of the heart very rarely follows an attack of rheumatic pericarditis occurring after the age of twenty years. An altered nutrition due to poisoning of the cardiac muscle would explain also the weak nature of the hypertrophy. Another manifestation of rheumatism in children is tachycardia, which may be due to a weakening of the myocardium. The conclusions of the paper in general are: (1) That dilatation of the heart ending in death may occasionally occur without valvular disease or general adhesion of the pericardium being present; (2) That in rare instances hypertrophy of the heart may occur without valvular disease or general adhesion of the pericardium; (3) That there is evidence that myocarditis may exist in the absence of pericarditis; and (4) That slight weakening of the myocardium may be shown by loss of physical energy, by attacks of cardiac pain, or by tachycardia.

The Lancet, June 14, 1902.

A New Method of Local Anæsthesia for Surface Operations.—This method, claimed as a novelty by E. A. Smith, is nothing but the application of cataphoresis to a surface covered with lint dipped in a solution of cocaine and adrenalin. He uses a current of 15 to 30 milliamperes passed for from five to ten minutes.

The Relation of Mental Symptoms to Bodily Disease.—Nathan Raw states that, after a long experience in the care of the insane and the personal certification of over 2,000 patients to asylums, he is firmly convinced that a large number of persons are certified as lunatics who are simply suffering from temporary insanity, the result of, or associated with, some form of bodily disorder or toxic poisoning. These people are not really insane, and should not be associated with lunatics. They quickly recover under proper treatment, and the author maintains that, from every point of view, it would be to the public advantage for them to be treated in a hospital for mental diseases, with expert physicians in attendance and a corps of students to study the acute phases of mental disorder, where the patient and his relatives might be spared the stigma of his having been detained in a public asylum as a certified lunatic.

Temporary Reminiscence of a Long-forgotten Language During the Delirium of a Bronchopneumonia.—Henry [illegible] reports the case of a woman of seventy years suffering from bronchopneumonia, which, though severe, ran a favorable course. During her delirium she began to talk in Hindustani, later in English, French, and German. The patient was born in India, which country she left at the age of three years and landed in England after four months' voyage, when she was four years old. Up to the time she landed she had been under the care of Indian servants and spoke no English at all, her only language being Hindustani. On her coming to England the ayah was sent back and she then began to learn English, and from that time had never spoken Hindustani. She apparently at first went back in her delirium to her early infant days, when she spoke again the first language she ever heard. A poem which she repeated over and over again was found to be something which the ayahs are in the habit of reciting to their children, and the conversations were apparently with the ayah, [illegible] a request that she might be taken to the bazaar to buy sweets. On the patient's recovery she was unable to remember more than a few words of Hindustani, nor had she any recollection of ever having been able to speak the language.

Early Peritonitis.—A group of cases is reported by W. H. Battle. They all presented abdominal symptoms of a mild type, varying but slightly. Each patient was seized with abdominal pain and each vomited and had a moderate elevation of temperature—in no case was it registered at above 102° F. before operation. The pulse did not, except in one instance, exceed 112, nor was the expression of any patient indicative of serious abdominal trouble. Yet in each case there was purulent peritoneal exudation of considerable amount within a few hours of the commencement of the illness, and in three of them there was perforation of the appendix, and in the fourth acute inflammation of that structure with a purulent collection outside it. In all these cases the mildness of the symptoms, in spite of the serious condition of the appendix, is striking. Inflammation of the peritoneum had already commenced, and it is unlikely that it would have become localized. Cases of this nature teach us that we should be on the early lookout for evidences of intraperitoneal effusion. This is the point of great importance in the early diagnosis of peritonitis. If it was more carefully considered, not so many cases would be brought to our hospitals in a moribund condition, or at least so far advanced that operative intervention is likely to be of little use.

British Medical Journal, June 7, 1902.

Gonorrhœal Synovitis in an Infant Suffering from Ophthalmia Neonatorum.—R. W. Innes Smith reports this case. Two days after the birth of the child a discharge from the eyes was noticed. The mother stated that for several months she had had a discharge from the vagina. The father admitted that he had had gonorrhœa six months previously. The ophthalmia was very severe. It was treated by syringing with 1 in 5,000 biniodide lotion every two hours night and day. When fifteen days old the child developed a well-marked synovitis of the right knee. The case was undoubtedly one of gonorrhœal rheumatism. This is a very rare affection in infants.

The Influence of Nasal Obstruction upon the Development of the Teeth and Palate.—Harry Campbell believes in the correctness of Whitehead's statement to the effect that nasal obstruction is capable of producing deformity of the maxilla. The resulting deformity constitutes a distinct pathological entity which the writer suggests should be called the mouth-breather's jaw. The narrowness of the hard palate in these cases gives it a false appearance of height. The writer refers to one etiological cause of this deformity—a reduction of atmospheric pressure in the nasal cavities, which induces a negative pressure within the antrum, and so prevents ample expansion of it, which is essential to the proper development of the maxilla. In the many hundreds of skulls which Campbell has examined in the museums he has not found one unmistakable instance of the mouth-breather's jaw, while there are hundreds of thousands of such jaws among the present inhabitants of London.

Widal's Reaction in a Case with Uric-Acid Calculus.—Arthur Maude states that there is no doubt as to the negative value of Widal's reaction. But it is certain that other conditions than typhoid fever will produce agglutinative reaction in typhoid cultures. The writer then reports a case which shows the difficulty of distinguishing between appendicitis and right-sided renal colic. A middle-aged woman passed a small stone from the bladder fifteen years ago. About 1899 she began to have typical attacks of recurrent appendicitis. At the third attack operation was performed, and there were found three concretions, which had escaped from an ulcerated appendix. These had sloughed into an abscess cavity, which had probably previously been separated from the bowel. She made a good recovery. Three weeks later she had a return of symptoms which might have been renal colic, appendicitis, or possibly mild typhoid fever. The blood gave a slight Widal reaction. [illegible] could not be obtained. Two days later the temperature fell and she became apparently well. Four days later she passed a large uric-acid stone, a month later another, and a month later a third. There is no evidence to show that she ever had typhoid fever.

British Medical Journal, June 14, 1902.

Malarial and Filarial Diseases in Barbadoes.—George C. Low states that in Barbadoes the medical men declare that indigenous malaria does not occur in the island. Cases are often seen in the General Hospital, but these have all come from some of the neighboring islands, where malaria is very common. No one could point to a case which had originated in the island itself. The writer has tried to find if any mosquitoes of the genus Anopheles are found in Barbadoes or not. There is one swamp which appears like a suitable breeding place for these insects. On investigation, however, although larvæ of a species of Culex and those of dragon flies and other aquatic insects were always found in abundance, no Anopheles larvæ could be discovered. People in the vicinity never suffer from fever, but enjoy remarkably good health. It is probable from the close similarity of this place to Anopheles-infested swamps in the neighboring islands that such larvæ could live here perfectly well; whether they have ever lived here and died out, or whether they have never existed, is a matter of speculation. The large amount of filarial disease in Barbadoes is in marked contrast to the absence of malaria. This is due to the extraordinary abundance of the common domestic mosquito, Culex fatigans, which acts as an efficient host for the spread of the disease. There should be a system of sanitary inspection, and mosquito nets should always be used.

Remarks on a Case of Hereditary Localized Œdema Proving Fatal by Laryngeal Obstruction.—T. Wardrop Griffith reports a most interesting case. The patient was a woman, aged eighteen years, when she first came under the writer's observation in 1886. From this time till her death in 1902, she was frequently seen by Griffith. The patient had four children, but pregnancy had no influence on the disease to which she was a victim. Her father from his earliest infancy had been affected with the same affection. On three occasions these attacks seem to have affected the throat. The third attack carried him off at the age of twenty-nine years. The swellings which this young woman presented were diffuse or circumscribed. They were usually pale, but sometimes slightly pink, and did not pit on pressure. They never became vesicular or bullous. In February of 1892 she felt that her throat was swollen, but as the swelling seemed to be passing backward, she thought that she would soon be all right. At noon, when her husband came home from his work, she started up, tried to speak, clutched at her neck, grew blue in the face, and died almost at once. Griffith made a series of transverse sections of the larynx which proved very instructive, for it showed that the œdema affected not only the mucous membrane but the deeper connective tissue, and even the substance of the muscles. This condition probably prevented the abductors from causing the necessary physiological enlargement of the aperture during inspiration. The œdematous fluid was purely of the serous variety, untinged with blood. The tissue covering the true vocal cords was decidedly affected.

The Œdema of Anæmia.—Thomas Houston sums up the interesting points which have suggested themselves to him in his observations on this subject: (1) The absence of loss of weight in anæmic conditions, and the fact that the patient seldom seems emaciated is mainly due to the fact that there is abnormal accumulation of fluid in the blood and tissues. If this excess of fluid were deducted it would probably be found that in these, as in other chronic illnesses, there is a progressive loss of weight in proportion to the severity and duration of the disease; (2) In the cure of such anæmic conditions, especially chlorosis, the first stage seems to be the getting rid from the blood and tissues of this excess of fluid; (3) A gain of weight in a case of pernicious anæmia under treatment, and without any improvement in the hæmoglobin, is to be regarded as an unfavorable sign, indicating dilution of the blood and consequent escape of serum into the tissues. It may, however, be a critical phase of the disease, and indicates the first step toward concentration of the blood. Immediately after this sudden increase in œdema there is either a marked improvement or the patient dies; (4) The œdema of anæmic condition seems to result from a hydræmic plethora of the blood, and is sowewhat different in origin and nature from the œdema usually found in Bright's disease; (5) Careful observations in the manner indicated of anæmic conditions, namely, a record of the weight and hæmoglobin value of the blood may furnish very interesting results. The points to direct attention to are the occurrence of hemorrhages (epistaxis, etc.), œdema, diarrhœa, and profuse sweating. The writer's observations convince him that these symptoms are often the result of dilution of the blood, and may be merely nature's method of counteracting the excessive and abnormal volume of the blood.

Deutsche medicinische Wochenschrift, May 29, 1902.

The Contagiousness of Carcinoma.—Radestock reports two instances in which the husbands of carcinomatous woman developed carcinoma. In the first instance the woman suffered from an ovarian carcinoma. Seven years after her death the husband, aged fifty-five years, sickened with an intestinal carcinoma which also proved fatal. In the second instance the wife died from a carcinoma of the œsophagus, and three weeks subsequent to her death the husband, aged seventy-seven years, began to show the first symptoms of a tumor in the same location. This proved to be a carcinoma, and death took place four months later. In neither instance did the husband give any hereditary history of carcinoma. The author does not believe that either of these cases adds much weight to the infectious theory of carcinoma, although the second case would be so regarded by the supporters of that theory. It should be remembered that in both instances the husbands were in that period of life during which carcinoma most frequently develops.

Enteroptosis and Its Costal Sign.—B. Stiller says that the variety of enteroptosis which invariably accompanies nervous dyspepsia is always of neurasthenic origin, and is always accompanied by a movable tenth rib. In all cases the presence of a movable tenth rib signifies that the trouble is constitutional and not mechanical in character. The presence of this sign is, therefore, not only of diagnostic, but also of therapeutic importance. By its aid the stomach specialist may easily differentiate between organic and functional disturbances. The neurologist may absolutely diagnose neurasthenia, the gynecologist may separate those cases which are mechanical from those which are dependent upon constitutional factors, and the specialist in children's diseases may early detect the presence of neurasthenic proclivities. The mobility of the tenth rib may vary greatly in degree. In many cases the unions between it and the ninth rib is only slightly altered from the normal. In a few cases the costal extremity of the rib is entirely free. In some of the latter the eleventh and twelfth ribs are entirely absent. The intensity of the deformity stands in direct relation to the intensity of the neurasthenic condition. Since this condition is essentially an asthenic of the nervous system, combined with an atony of the general muscular tissue, the author proposes for it the name of "asthenia universalis congenita."

Berliner klinische Wochenschrift, June 2, 1902.

Splashing Sound.—Hans Elsner says that the splashing sound is not necessarily a pathological symptom, and is not, as Stiller thinks, diagnostic of atony of the stomach. Elsner has examined twenty-six women whose stomachs were perfectly normal and found a distinct splashing sound in ten. It is evident, therefore, that other symptoms must be present in order to render the diagnosis of atony of the stomach sure, and he who will make such a diagnosis on the mere presence of the splashing sound will often be deceived.

Protective Inoculation against Anthrax.—G. Sobernheim has obtained an anti-anthrax serum by inoculating horses, cows and sheep with increasing doses of highly virulent anthrax cultures. Sheep and cows were then experimentally protected against anthrax by inoculation with this antiserum. In the first set of experiments the antiserum alone was inoculated and a passive immunity thus produced. For this purpose the initial dose of the antiserum was 10 c.c. This amount was increased in the subsequent inoculations, the largest quantity used at one time being 100 c.c. In the second set of experiments slightly virulent anthrax cultures were inoculated at the same time with the antiserum and a combined active and passive immunity produced. The amount of anthrax culture inoculated at one time varied from .5 to 1 c. c. and the coincidently inoculated antiserum from 5 to 15 c. c. By both of these methods it was possible to absolutely protect sheep and cows when inoculated, experimentally, with highly virulent anthrax cultures. These methods were then put into practical use, in that animals living in regions infected with anthrax were immunized. At first the antiserum alone was used, but the passive immunity thus produced was found to be very transient. The combined method was then employed and a much more durable immunity obtained. None of the animals treated in the latter manner developed anthrax, although many of the uninoculated in the same flocks or herds contracted the disease and died therefrom. This combined method is much to be prefered to the use of the Pasteur vaccine, since it in no wise injures the animal, and one inoculation is sufficient to produce a complete immunity. Furthermore, the immunity thus conferred is more lasting and of a higher degree. Additional experiments have shown that in many cases anthrax may be cured by the use of the antiserum alone. This is not possible with the employment of the Pasteur method.

Münchener medicinische Wochenschrift, June 3, 1902.

Sudden Heart Failure.—Jorus reports a case of sudden heart failure as the result of over exertion in a powerfully built, healthy man. Death took place in three days with marked dilatation of the left ventricle. It is most probable that the cause of the heart failure is to be ascribed to an instantaneous over-straining of the healthy heart muscle and its permanent injury thereby.

A Pathogenic Streptothrix Isolated from Sputum.—W. Rullmann reports a case which has been under observation for five years, and from the sputum of which a streptothrix has, repeatedly, been isolated, oftentimes in pure culture. When grown upon Lœffler's blood serum the morphology of this microorganism greatly resembles that of the diphtheria bacillus, the bulbous extremities, however, are very prominent. The Röntgen picture of the thorax shows the presence in the left lung of three small circumscribed shadows. At the base of the right lung one small shadow is also seen. The movements of the diaphragm on the left side are normal, but on the right side they are somewhat restricted. During the last few months iodipin has been the chief therapeutic agent used. Too short a time, however, has elapsed to admit of a definite opinion with respect to its value in this condition.

Nasal Dysmenorrhœa.—F. Linder, under this name, considers those cases of dysmenorrhœa, which are accompanied by an inflammation of the nasal mucous membrane. Fliess has shown that such an inflammation usually develops in two typical locations: (1) On the mucous membrane of the inferior turbinate body, and (2) On the mucous membrane of the tuberculum septi. He says, moreover, that the application of a 10 to 20 per cent. solution of cocaine to the inflamed mucous membrane in these locations is a specific for the dysmenorrhœa, in that the pains are quickly cut short thereby. Linder confirms this statement, as the result of the observation of sixteen cases. In all of these the pains were almost instantaneously relieved by such applications. In most of the case the pains returned after about twenty-four hours, but were again relieved by renewed applications. In order to determine whether suggestion was at all responsible for the results obtained in several of these cases during subsequent attacks, the cocaine solution was replaced by water, either cold or lukewarm. In one of the cases the water produced no effect, but in all of the others the pains were somewhat relieved. This relief, however, was not nearly so marked and of such long duration as with the use of cocaine. It is evident, therefore, that suggestion is responsible for a certain portion of the beneficial results obtained, but that it does not play the entire part therein.

French and Italian Journals.

The Hæmolytic Power of Aqueous Extract of Tumors.—From his experimentation in this line, G. Panzacchi concludes that the watery extracts of sarcoma, carcinoma, and adenoma have a hæmolytic power. This power is not specific for human corpuscles, but acts upon those of the dog, the rabbit, and the guinea-pig. The extract is not specially active for several days after its preparation, but increases rapidly in its hæmolytic power, and loses it again after a certain time.—*La Riforma Medica*, May 31, 1902.

The Semeiological Value of Partial Epilepsy.—G. Seppilli, discussing the question of the value of partial or Jacksonian epilepsy in the diagnosis of the seat of cerebral lesions, holds that it cannot be considered as an infallible sign of a morbid organic process in the Rolandic zone, but that it is not accurate to assert that it has no diagnostic value. He reports two cases in which the [illegible] May 21 [illegible]

The Pharyngeal Cough of Children.—[illegible]

Ankylosing or C[illegible] Arthritis.—[illegible]

A Case of Chorea Minor from Intestinal Intoxication.—[illegible] reports the case of a little girl [illegible] that she was a victim of chronic constipation, having a passage from the bowels only every ten or twelve days. [illegible] by the administration of [illegible] which were almost perfectly black and unusually fetid [illegible] were given [illegible] and caused the copious discharge of hard, black, fatty matters. The daily administration for about ten days of a [illegible] produced the most remarkable [illegible] in the child's symptoms, and in about two months a complete cure was obtained.—[illegible]

A Rare Case of Congenital Deformity of the Nose.—[illegible] reports the case of a little girl of eight months, the left side of whose nose was entirely normal, while on the right side there was a trumpet-shaped appendage about two centimeters long and [illegible] wide. The [illegible] part of this appendage was inserted between the inner canthus of the eye and the root of the nose, and was covered with normal skin. The rest of it was free, and at the external extremity was a small orifice, which led to a narrow canal that extended throughout the appendage, and through which air came out when the child cried. The author removed the growth in such a way as to make a new nostril, and the results of the operation were entirely satisfactory. The abnormality was probably due to an arrest of development at about the eighth week of fetal life.—[illegible], May 15, 1902.

Annals of Surgery, June, 1902.

The Surgical Aspects of the Status Lymphaticus.—From an experience of seven cases, J. A. Blake notes that five occurred in [illegible], six were adults, evidences of tracheal compression by the thymus were wanting. He says that anesthesia in patients suffering with status lymphaticus is at least frequently fatal. Chloroform in these cases is especially dangerous. Death may occur during anesthesia or some hours after, the evidences being those of cardiac and respiratory failure. We have no positive means of diagnosticating this condition previous to operation, the most suggestive condition which should put us on our guard is lymphatic hyperplasia. The article concludes with a bibliography.

Sarcoma of the Mesentery.—A. C. Bernays contributes the clinical history of a case under personal observation. Operation was done under chloroform and recovery was uneventful. The removal of the tumor necessitated the removal also of all the ileum except three or four inches which were left attached to the ileo-cecal valve and a part of the jejunum, the whole length of bowel removed being 119 inches. An analysis is made of thirty-six cases of resection of small intestine collected from surgical literature. The analysis shows that in the thirty-six cases including the author's death occurred quickly [illegible]

Fracture of the Base of the Fifth Metatarsal Bone by Indirect Violence.—[illegible] When the heel, therefore, is off the ground, the body weight exerts itself upon the fifth metatarsal twisting it slightly inward. The [illegible] takes place at its base, where the strongly attached ligaments resist its displacement. A fracture occurs therefore exactly where one would expect it to occur. Crepitus is not felt, probably because the line of fracture runs toward the [illegible] ligament, and the fragments are therefore fixed or because [illegible]. [illegible] the article show [illegible] the line of fracture cannot be traced quite through the bone, but there can be but little doubt that the fracture is complete. The difficulty in tracing the fracture-line added to the fact that [illegible] a wedge [illegible] is suggestive of impaction.

Studies in Pathogenesis of Appendicitis.—[illegible] states that when we consider the situation of the organ, we can readily understand that it must often be subjected to alternating periods of anemia and hyperemia. If such a disturbance of circulation causes a superficial destruction of epithelium we would have a condition favoring the invasion of the mucous membrane by the B. coli communis. The character of the inflammation produced is [illegible] like that caused by a [illegible] organism [illegible] allied to this variety, the typhoid bacillus. [illegible] hypertrophied and enlarged, almost occluding the lumen of the appendix. These [illegible] break down, giving rise [illegible]. They may perforate the entire thickness of the [illegible]. A vessel may become eroded and we may have a hemorrhage into the appendix or beneath the mucosa. In those cases in which we have a foreign body or a particle of hardened feces finding its way into the appendix, the process is different. Here the disease partakes of the character of a catarrhal or desquamative inflammation which leads to the formation of concretions. A section of such an appendix through the concretion will show that at least the outer half, and in many cases nearly all of the concretion is made up of closely packed cast-off cells cemented together with mucus. A small particle of hardened feces or a foreign body may form the nucleus. These cells are derived from the cast-off epithelial cells lining the appendix and tubular glands and the exuded lymphocytes. The cells will be seen to be gradually losing their staining power as one passes toward the center of the concretions, that is, the older or central cells have lost their chromatic substance, the younger or peripheral cells, being but recently cast off, retain it. Such a concretion by pressure exerts a deleterious influence upon the bloodvessels of the mucosa, compressing the superficial capillaries, thus bringing about the death of a new layer of cells, which become in turn a part of the concretion. In this way we may have a progressive enlargement of the concretion at the expense of the wall of the appendix, until, by pressure, we may have at some point all of the capillaries occluded, there then follow necrosis and perforation.

Society Reports.

ILLINOIS STATE MEDICAL SOCIETY.

Proceedings of the Fifty-second Annual Meeting, Held at Quincy, May 20, 21 *and* 22, 1902.

The society met in the Superior Court Room of the Court House, under the Presidency of Dr. John T. McAnally of Carbondale.

Prayer was offered by Rev. S. A. Dana, after which an address of welcome was delivered by Hon. J. A. Steinbach, Mayor of Quincy, which was responded to by the President.

The society adopted a new Constitution and By-Laws, in conformity with the plan of reorganization of the American Medical Association. It also endorsed a bill providing for a state board of medical examiners, which is to be separate and distinct from the State Board of Health.

After the transaction of considerable routine and miscellaneous business, the society divided itself into sections, and the reading of papers was begun.

General addresses were delivered by Dr. Chas. B. Johnson of Champaign, who selected for his subject "A Country Doctor's Contribution to Preventive Medicine;" "Pernicious Anæmias, their Diagnosis and Treatment;" by Dr. George Dock of Ann Arbor, Mich.; "Surgical Intervention in Borderland Cases," by Dr. Roswell Park of Buffalo, N. Y.

President's Address.—This was delivered by Dr. JOHN T. MCANALLY of Carbondale. Matters of general interest to the profession and the laity were discussed.

La Grippe Infection Resembling Puerperal Fever.—Dr. JOSEPH BRAYSHAW of Homer gave a resumé of the literature of infection resembling puerperal fever. He also dwelt upon the methods of diagnosticating the same. He said the prognosis was usually unfavorable. He reported a case of la grippe infection in a tuberculous patient, followed by childbirth at seven and one-half months, after which patient developed pneumonia, peritonitis, pleurisy, pericarditis, nephritis, with, finally, general septic infection and death.

Treatment of Septic Conditions of the Uterus. This was the title of a paper by Dr. M. S. MARCY of Peoria. He said the uterus was a very fertile field for introducing poisonous material into the circulation. He spoke of the treatment of septic conditions after confinement. Special attention should be given to the treatment of these conditions after actual abortion. The different opinions of writers were given. He spoke of the curette in the hands of the general practitioner, and, finally, discussed the best remedy for intrauterine infections.

The Stokes-Adams' Syndrome, with Report of Cases.—Dr. FRANK BILLINGS of Chicago gave a brief account of the phenomena which characterize the syndrome described by Stokes and by Adams, the character of the pulse and syncopal attacks; the cardiovascular conditions in which the phenomena may occur. He gave a brief account of two cases in which the syndrome appeared; one with a clinical diagnosis of aneurysm of the aorta, the other one senile arteriosclerosis and fibrous myocarditis. The diagnosis and treatment were discussed at length.

Life Insurance Examinations.—The author of this paper, Dr. H. B. BUCK of Springfield, stated that policy demanded that any accepted duty in this line must be done in a thorough, painstaking manner, irrespective of the size of fee. That anything short of honest, painstaking work reflects upon the profession as a body. That suspicion as to the honesty of the profession (entertained by the life insurance companies) can only be remedied by widespread individual effort, each examiner realizing in every case examined that his work tends either to weaken or strengthen that suspicion. That truly careful and scientific professional work would lessen the percentage of premature deaths from diseases of lungs, heart and kidneys. In other words, either carelessness, undue haste, or both, might result in overlooking the incipient evidence of diseases that by and through rapid development and fatal termination furnished too many proofs of death. He then discussed the necessary qualifications for and the technique of the work.

Typhoid Fever in Children.—Dr. I. A. ABT of Chicago, in a paper on this subject, reported ninety cases of this disease in children. He spoke of the prodromata and of the symptoms which mark the onset of the disease; the relapse and date of its occurrence, severity, duration and special symptoms, the pulse, temperature, nervous symptoms, headache, delirium, muscular tremor, neuritis and chorea, the tongue, mouth and pharynx, epistaxis, the intestinal symptoms, diarrhœa or constipation, hemorrhage, perforation, tympany, vomiting, special symptoms, the liver, size and consistency, the lungs, bronchitis, pneumonia, special considerations, the heart, dimensions and physical examination, the larynx, the skin, roseola, date of appearance, location and duration, and occurrence during relapse, abscesses, furunculosis, erythema, bed-sores, unusual conditions, organs of special sense, examination of urine, diazo-reaction, examination for typhoid bacilli and other microorganisms, probable source of infection in cases, including a consideration of house epidemics, the Widal reaction, its occurrence, technique, complications, daily observations, termination of the disease, and autopsial reports.

The Infant's Clothing.—Dr. A. C. COTTON of Chicago, in a paper with this title, discussed the objects of special requirements on account of anatomical and physiological peculiarities; form and material best suited to meet these requirements; the pernicious effects of improper clothing; lowered vitality; impaired nutrition; arrested development, and permanent deformities.

Miliary Tuberculosis.—This was the title of a paper by Dr. FRANK X. WALLS of Chicago, in which he reported an interesting case of miliary tuberculosis in an infant. He considered the etiology, symptomatology, and the diagnosis of miliary tuberculosis in general.

What Should We Teach the People in Regard to Tuberculosis?—Dr. GEORGE W. WEBSTER of Chicago contributed a paper on this subject. He divided the question into three divisions: (1) Those who are not affected with the disease, especially the wealthy class. What is their duty to others? (2) Those not affected, but especially liable, because of heredity or because some near friend or some member of the immediate family is tuberculous. (3) Those already afflicted. Physicians should aim to make their suggestions and help simple and practical rather than difficult and scientific. Efforts should necessarily be directed chiefly toward the second and third classes. Patients should be taught that there are two elements in the case; the susceptibility of the patient, and the germ. We should then teach them how immunity is lessened or destroyed, and how it may be regained. We should teach them the sources and modes of infection, and the methods of preventing the same. They should be taught their duties to themselves, their families and the public.

Senile Pneumonia.—Dr. D. W. REID of Jacksonville presented a paper with this title. He said that senile pneumonia meant acute croupous or lobar pneumonia, as it affected the aged. The importance of a disease depended on its frequency and its mortality. Senile pneumonia was the most frequent and deadly disease in old age; it was the natural end of the old man. He said that nine-tenths of all deaths over seventy-five were due to acute lobar pneumonia. The etiology was the same as sthenic pneumonia in the young adult, namely, invasion by the pneumococcus of Fraenkel. It was, probably a local infection with general toxæmia. Authorities, however, differed on this point. There was more to be learned about the real cause of pneumonia than of any other common acute disease. He then discussed at length the symptoms, prognosis and treatment.

Pathology of Kidney in Pneumonia.—In a paper on this subject, Dr. F. C. [illegible] of Galesburg discussed the physiologic elimination of toxins through the kidneys, the the microscopic appearance of kidney in croupous pneumonia, blood supply and congestion, changes in epithelial tissue, changes in connective tissue, changes in Malpighian tufts, changes in blood vessels, also leucocyte infiltration, lymphocytic infiltration, plasma cell infiltration, presence of granular and hyaline casts, presence of pneumococci, the conditions of the kidneys when death occurs early or late in the disease, the suggestions on causes of congestion, parenchymatous degeneration and effects of toxins acting a long or short time or in large or small amounts; the influences which bring about lymphocytic, leucocytic and plasma cell infiltration; and suggestions on the effects of plasma cells and lymphocytes.

Treatment of Pneumonia.—In discussing this subject, Dr. N. S. Davis, Jr., mentioned as measures of treatment bleeding, tartar emetic, blistering, fomentation, veratrum viride, aconite, [illegible], fresh air, hypodermoclysis, warm baths, oxygen inhalation, digitalis or strophanthus, strychnia, ammonium compounds, alcohol, [illegible], chemical antipyretics, cold baths, antipneumococcic serum; and the prophylaxis of the disease.

Certain Clinical Points Regarding the Use and Indications of the Cardiac Stimulants.—A paper with this title was read by Dr. Arthur R. Edwards of Chicago, in which he discussed the use of nitroglycerin, also its contraindications. He likewise spoke of the use of atropine, its action on the circulatory and respiratory apparatus, and mode of administration. The action of alcohol was considered, especially upon the respiratory center and circulation; also its effect on the vasomotor system. He mentioned its use in acute infections, typhoid, etc. He dwelt upon the use of morphine and its effects in respiratory and circulatory lesions, the indications for the use of digitalis, contraindications, adjuvants and substitutes.

Prognosis and Treatment of Suppurative Pleurisy.—Dr. E. Fletcher Ingals of Chicago, in a paper with this title, gave an analysis of eighty-three cases from private records and those from the Presbyterian and Cook County hospitals, with a study of the relative value of different methods of treatment.

He said that empyema was extremely fatal, although in the majority of cases, in children and in others when caused by the diplococcus lanceolatus, it might be cured by appropriate measures. Of twenty patients under fifteen years of age only two died. Of sixty-three older patients twenty died; total death rate after operative measures in all cases, 28 per cent. Although rarely patients recovered by absorption of the fluid and encapsulation of the remaining pus, and a considerable number by perforation of the lung and expectoration of pus. Of those cases due to the pneumococcus, according to Jaccoud and Netter, from 25 to 40 per cent recovered without operation. In children under three years of age the mortality was about 50 per cent; from this to the fifteenth year, according to some statistics, the mortality was as low as 2 or 3 per cent. Hippocrates recommended tapping, also perforation of the rib, an operation not very dissimilar to the exsection practised to-day. Laennec considered the disease very fatal and recommended paracentesis, but had never himself obtained permanent benefit from the operation. Of 121 cases collected by Faulk twenty-three were cured by aspiration alone. Four of the author's cases were cured in the same manner. John Sculteus, in the early part of the seventeenth century, recommended the withdrawal of pus by a syringe. Repeated aspirations were urged in all cases before a radical operation was performed until the pleural cavity could be more thoroughly emptied. Four or five days later a radical operation should be done. The introduction of two large drainage tubes through a trocar was believed to be the simplest and best operation, because it could be done by the physician without the aid of a surgeon; it did not require general anæsthesia, and gave the patient less discomfort and apparently saved more lives than the most formidable operation. An examination of these eighty-three cases, which were due to various causes and to various complications, and treated under various methods, showed 72 per cent. recovered under operation recommended, and only [illegible] per cent. recovered after excision of ribs. Statistics appear to show that [illegible] when temperature is present, cases did better by drainage without irrigation than with it after operation. In case a cavity remained for four or five months after operation, the resection of portions of two or more ribs was recommended to allow collapse of the side, so that the walls of the cavity might come in apposition and healing take place.

Alcoholic Neuritis, with Report of Case.—In this paper the author, Dr. C. [illegible] Wood of Decatur said that alcoholic neuritis was the most frequent type of multiple neuritis, which was first described by Jackson in 1822. The disease was more common in women in the middle period of life. The symptoms were motor, sensory, trophic and mental. He dwelt at length upon the differential diagnosis from anterior poliomyelitis, tabes dorsalis, and [illegible], and discussed at length the prognosis and treatment. The case was a male, aged thirty-six years, who had taken a small amount of alcohol for ten years. The disease was gradual in its onset, attended by severe pains and mental symptoms. Wrist drop occurred without foot drop. Under treatment there was a gradual improvement of the paralysis.

Disorders of the Nervous System Due to the Severe Anæmias.—Dr. Archibald Church of Chicago read a paper on this subject. He considered the various lesions of the nervous system which have been recognized for a long time as the result of, or at least associated with, severe anæmias. He pointed out the changes in the spinal cord due to or associated with the pernicious anæmia. He gave a summary of the clinical manifestations of such disorders. He reported briefly a number of cases, dwelt upon the pathology of the condition, and the indications for treatment.

Marked Changes in the Blood from Small Repeated Hemorrhages.—Dr. Frank Billings of Chicago said that small repeated hemorrhages from whatever source may, if long continued, induce marked changes in the blood, as well as in the general condition of the patient. In some instances these cases at first sight resemble pernicious anæmia. The characteristics of the blood, however, are those of a severe secondary anæmia. He detailed the histories of cases illustrating the above points.

The Psychoses in Bright's Disease.—Dr. C. Barlow of Robinson, in a paper with this title, stated that mental disturbances might become manifest in every variety of nephritis, but were most frequent in the chronic interstitial variety. For convenience of study, the mental symptoms were divided into four groups. The first group consisted of those in which there were the mildest forms of mental disturbances, such as loss of memory, confusion of thought, and occasionally mild delirium and temporary loss of consciousness. The second group of symptoms included acute delirious uræmia, coma, and the mental symptoms resulting from convulsions or paralysis. The third group comprised insanity occurring in patients who were not predisposed through heredity. The fourth group embraced cases of insanity occurring in individuals who had hereditary tendencies. The causes of the psychoses in nephritis were expatiated upon, and the importance of the subject from a clinical and from a medico-legal standpoint emphasized.

Exophthalmic Goiter.—Dr. L. Harrison Mettler of Chicago contributed a paper with this title. He reported three cases in a mother and her two sons.

He said the classification of this disease had been various in the past. To-day its real nature was hardly less mysterious than it was formerly. As with all such affections, theories were rife. Dogmatic assertions in regard to it were certainly not allowable. Three prominent views of it were that it was a neurosis of the central nervous system; a hypersecretion of the thyroid gland, or a combination of neurosis and hypersecretion reacting mutually upon each other. That it was not due to hyperthyroidization primarily was shown by its etiology (heredity, age, sex, mental shock, anæmia, etc.). By the peculiar symptomatology (alternate prominence of tachycardia, struma and exophthalmos; hyperidrosis, trembling, psychic state, and other secondary symptoms) by the pathologic findings (condition of thyroid gland, of blood and other organs); by the prognosis (cases often suddenly recovering under influences other than those that affect the thyroid gland); and, lastly, by the therapy (rest, electricity and nerve sedatives, usually giving the best results). On the other hand, all these factors pointed strongly to a neurotic origin for the disease.

Exophthalmic goiter and myxœdema were not antithetical, except in some few minor symptoms, hence, if the latter was due to diminished secretion, it was not to be concluded that the former was due to an excess of thyroid secretion.

Recent Advances in the Treatment of Epilepsy.—Dr. Harold N. Moyer of Chicago spoke of the effects upon epileptics of diminution of salt ingested, and discussed the dietetics of epilepsy in general, also the use of the glandular extracts, notably suprarenal, in the treatment of idiopathic epilepsy, and presented a simple chart for the daily record of the condition while under treatment.

Dr. E. M. Eckard of Peoria discussed hydro- and electrotherapy in the treatment of diseases of the alimentary tract.

Some Essential Points Regarding Chronic Constipation of the Bowels.—The author of this paper, Dr. J. W. Hensley of Peoria, spoke of the causes which bring about the atonic condition of the intestine, which he said should be searched for and corrected, if possible. The middle classes of the adolescent and adult people of civilized countries were the ones most addicted to irregular action of the bowels, because of occupation, sedentary habits, hurry and worry in business, improper diet, neglect in the beginning, environments, the frequent use of active purgation, etc. Hence, constipation from these causes might be said to be idiopathic. Defective digestion, insufficiency of food, anæmia, chlorosis, and all other conditions weakening intestinal peristalsis, without other or remote local or constitutional disease, were considered within the scope of the paper. All grave continuous constitutional diseases, local organic affections, obstructions, together with the sequelæ thereof, except simple gastric or intestinal atony, were excluded. To cure chronic constipation, even though all organs might be anatomically and physiologically normal in the essential, required tact, confidence, and long-continued treatment, hygienic, digestant and medicinal, all of which must be regular and persistent. Confidence on the part of both patient and physician, inspired by experiences and autosuggestions, were indispensable aids in the management of all outdoor patients, especially so where the digestive and eliminative functions were impaired. Regular habits, exercise of a healthy physical nature, the proper and full ingesta of wholesome foods with both gastric and intestinal sufficiency of digestion, were important conditions to be considered. These, together with an understanding and agreement from the beginning, to remain under treatment and observation for at least six months, would, in a great majority of cases, result in a permanent cure. The treatment must be pursued on rational conservative bases. No doubt should be expressed or conveyed as to a favorable outcome. With a due observance of prescribed hygienic measures, a properly selected diet and exercise, together with a studied treatment by medicines, manipulations and suggestions, according to conditions, causes, and the idiosyncrasies of each individual case, would almost always result favorably in the end.

Concerning A New Series of Synthetic Salts; the Nucleids of Iron, Copper, Mercury and Silver.—Dr. E. R. Larned of Chicago discussed this subject. He said synthetic chemistry was particularly useful, by imitating nature and building in the laboratory remedial agents similar to those of nature's construction. The irritating and devitalizing action of most germicides was explained upon the ground of chemical affinity for tissues and cell constituents. The most important constituent of blood and lymph corpuscles was nuclein. Health was maintained and resistance to disease effected through the defensive proteids of which nuclein was the most active. These new salts were true chemical combinations of the metals with nucleinic acid. The therapeutic application of compounds of nucleinic acid was rational and supported by abundant clinical observations. Inorganic salts of the metals must undergo reformation into nucleids before the organism could make use of them.

Malarial Hematuria.—Dr. L. M. Winsted of Wetaug read this paper. The author having had considerable experience with this disease, he gave a brief account of the pathology and etiology as now taught from different standpoints. He outlined the symptoms and treatment in detail, paying particular attention to the different methods of treatment, particularly in reference to the administration of quinine, and took the ground that quinine was, if not contraindicated, of very little use in the treatment of the disease. Three theories of the cause of the disease were mentioned, namely, malarial, quinine and specific. Eliminative treatment, or a clearing of the alimentary canal and the active stimulation of the excretory organs were advocated, together with the use of quinine, arsenic and strychnine following later. The author narrated ten typical cases of the malignant type of the disease.

Unusual Case of Typhoid Fever.—Dr. J. W. Kelly of Springfield reported a case of typhoid fever of sudden development; chills and hyperpyrexia, the chills failing to recur, and temperature was reduced by the administration of large doses of quinine and capsicum. No plasmodia were found in the blood. There was a continued perversion of ideas, amounting at times to marked, and at one time wild, delirium, which continued even while the temperature was normal and subnormal. These marked changes in temperature amounted to complete intermission for several days. There were likewise marked and sudden changes in the pulse and respiration.

Consistency in Medical Practice.—Dr. J. N. Nelms of Taylorville said his paper was written in defense of the legitimate practice of medicine. He called attention to the requirements demanded by law and deplored the fact that many, after having attained the requisite knowledge to practise scientific medicine, denounced internal medication and resorted to irregular processes as a substitute. He did not underestimate the value of hydrotherapy, suggestion, massage, etc. They were valuable as aids, but could never take the place now held by scientific medicine. He pointed out the inconsistency of legislating against osteopathy and at the same time resorting to massage exclusively, or condemning Christian Science while practising suggestive therapeutics to the exclusion of drugs. To secure legislation in behalf of the profession, physicians must be consistent. Some insisted that the tendency was toward nihilism. He condemned this idea as dangerous to the profession.

[illegible] fully [illegible]

Surgery of the Stomach.—In a paper on this subject Dr. [illegible] of Chicago [illegible] procedures should be resorted to. He gave a [illegible] and [illegible] should be [illegible] more frequently. He [illegible] perforating [illegible], and said that perforating [illegible] should [illegible]. In [illegible] practice, however, the [illegible] treatment [illegible] preferable. The history of [illegible] was discussed under six heads: Preliminary preparation of the patient, [illegible] anesthesia, operative technique, the after-treatment, complications, and causes of death.

Rupture of the Liver.—Dr. J. L. W[illegible] of East St. Louis read a paper on this subject. He said that the [illegible] even when [illegible]. He cited a case in point with pain and a history of traumatic injury indicating involvement of the viscera in the left side of the abdomen [illegible]. He [illegible] the subjective signs. Laparotomy revealed a rupture of the liver on its upper surface. The secondary operation was made for drainage through the right chest wall. During the second week the eighth and ninth ribs were excised for the purpose of establishing direct drainage. A biliary fistula resulted, which closed spontaneously during the third month, followed by recovery.

Lymphadenitis and Abscesses of the Liver as Complications of Appendicitis.—Dr. M. L. Harris of Chicago discussed this subject. The complications considered did not depend upon the severity of the local changes found in the appendix. A severe lymphangitis or lymphadenitis might be present in mild cases of appendicitis. An appendicitis so mild as to escape detection might form the infection atrium through which microbes might enter the lymph channels and set up a severe lymphadenitis, or might enter the portal circulation, producing a severe pylephlebitis with secondary abscesses in the liver. These complications might also take place some time after the acute symptoms of appendicitis had subsided. In cases of general infection, with symptoms pointing to the involvement of the liver, the appendix should always be thought of as a possible point through which the infection had gained entrance.

Appendicitis: When Shall We Operate?—In a paper with this title Dr. H. C. Mitchell of Carbondale condemned the practice of wholesale operating in these cases in all stages of the disease. He recommended operation only in certain stages, preferring to allow the patient to take chances of recovery otherwise. He gave statistics proving his claims.

A Plea for the More Accurate Diagnosis of Cholelithiasis.—Dr. [illegible] of Freeport reported forty cases in point, with a consideration of [illegible] diagnosis. He [illegible] the more important differential points between the above condition and [illegible], gastritis, appendicitis, renal [illegible], hysteria, neuralgia, and [illegible] disease.

Malignant Disease of the Kidney in Children.—Dr. [illegible] of Galesburg reported a case of malignant disease of the kidney in a child, with a pathological report by Dr. Wm. H. Welch of Baltimore. The [illegible] of malignant disease of the kidney [illegible] 1891 [illegible]. Over [illegible] per cent. of all malignant tumors of the kidney occurred before the age of [illegible] years. [illegible] The [illegible] of malignant disease of the kidney had been [illegible] by Cohnheim's theory of embryonic cell rests. [illegible] Malignant tumors of the kidney [illegible]. The tumor was pronounced by Dr. Welch as a [illegible].

Surgery of Ureters.—In a paper with this title Dr. Emil Ries of Chicago discussed [illegible] the necessity of treatment in connection with tuberculosis of the kidney and bladder and also plastic surgery in cases of [illegible].

Technique and Possibilities of Endovesical Operative Procedures.—Dr. Louis E. Schmidt of Chicago discussed [illegible]. He described the essential features of the two distinct types of operating cystoscopes, namely, the Nitze, and the Casper. He favored the use of the K[illegible] operating cystoscope, as [illegible] that the operator works under direct vision. The lamp and window were situated on the [illegible] of the beak. To the under part of the cystoscope was attached a canal through which the different instruments were introduced into the viscus. Their working end appeared [illegible] in front of the window. He then considered the technique and limitations of endovesical operative procedures, the frequency of cases for procedures of this kind, and the results.

Prostatectomy.—In a paper with this title, Dr. John B. Murphy of Chicago, after detailing several interesting cases in which he performed prostatectomy, drew the following conclusions.

(1) From the clinical reports and experience, in extreme cases prostatectomy is the operation of election. (2) It appears evident that in the hands of safe, far-seeing, informed practitioners, few cases will now be allowed to progress to this extreme condition before radical measures are resorted to for permanent relief. The practice of to-day should be timely practice. (3) Continued use of the catheter is a menace to life not to mention its discomfort, no matter how favorable the [illegible] for its performance. The patients all, sooner or later, suffer from cystitis and its sequelæ. (4) Prostatectomy gives the best permanent result, and is fraught with very little more danger than prostatotomy. (5) Suprapubic prostatectomy should be limited to exceptional cases of enormous intravesical enlargements of the prostate. It appears to us to endanger the sphincteric control more than the perineal

operation. It is more sanguinary and the work is more difficult and distant from the operator; (6) The perineal is the most direct and least bloody route. It admits of a very large opening, and permits the prostate to be drawn quite into the open before it is attacked. It gives the greatest security against injury to the bladder wall and least inability to disturbance of the internal sphincter. It endangers the rectum least and affords the best drainage; (7) It can be best performed through a Y-shaped incision, with a Sims' speculum for a posterior retractor. The prostate is drawn out easily with sharp hook retractors, and best separated from the bladder from behind forward. The operation should never be performed in the dark, *i. e.* through a small incision; (8) It should always be an intracapsular enucleation *en masse*, allowing the anterior isthmus to remain. The hemostasis may *be* secured with forceps or a packing of subiodide of bismuth (not iodoform) gauze. The permanent catheter should not be introduced until the perineal drain is removed; (9) The patient should be kept in a semi-sitting position for seventy-two hours after the operation, and should be out of bed by the fifth day. He should drink large quantities of water from the onset; (10) Anæsthetic is *sub judice*. Phosphate of sodium should be administered to keep the urine acid; and urotropin as an antiseptic. The personal equation must never be lost sight of in operating these cases, and attention to every small detail of the patient's general condition is necessary for the best results.

The Accidents of Anæsthesia; Their Prevention and Treatment.—Dr. D. N. Eisendrath of Chicago, in a paper on this subject, spoke of the survival of ether and chloroform as the chief agents for the production of general anæsthesia. He said there was a gradually increasing usefulness for the method of local anæsthesia of Schleich. He gave a comparison of the action of chloroform and ether on healthy and diseased organs. He mentioned the chief indications and contraindications in the use of these anæsthetics; the method of administration of each, and how it had been improved since the recent researches of various investigators. He discussed the matter of how to prevent grave cardiac, pulmonary and renal complications; also the treatment of chloroform syncope by raising the foot of the table, resorting to massage of the heart, rhythmical tractions of the tongue, and artificial respiration, which should first be employed. He then alluded to the necessity of having everyone understand the need of system in the application of methods of resuscitation. As methods of last resort, he mentioned the plan of Prus, intratracheal insufflation of air, etc.

Transverse Arrest of the Head an Indication for Forceps.—Dr. Chas. B. Reed of Chicago read this paper, in which he said that the impacted head was found low down in the pelvis with the saggital suture parallel to the transverse diameter of the pelvis, the fontanelles on about the same level, and no tendency to forward rotation of the occiput. Deep transverse arrest of the head was recognized thirty-two times in the last 3,600 labors at the Chicago Lying-in Hospital, or 9 per cent. According to Munch, the condition occurs in I-paræ in 81.61 per cent. of all the cases, and is due to the early descent of the head into the pelvis. This unusual frequency in I-paræ was not borne out in the Chicago Lying-in Hospital statistics. Here eighteen cases occurred in multiparæ, and fourteen in I-paræ. Flat pelves, general contracted pelves, the too large pelvis (47 per cent. of Ahlfeld's cases), exostoses of the sacrum and symphysis, insufficiency of the powers of labor, pendulous abdomen, and dolichocephalus were also of etiological importance. The diagnosis was readily made by vaginal examination The danger to mother and child arose from the great prolongation of the labor and the consequent evils; sepsis, fistulæ, necrosis, hemorrhage, and so forth. Cases were treated either by position on the side, by manual correction or by forceps. In the Chicago-Lying-in Hospital service the maternal conditions furnished the most frequent indication to terminate the labor. Forceps were applied twenty-three times; head spontaneously rotated nine times; forceps applied in the oblique diameter of pelvis which corresponded to the position of the occiput. The head was grasped by the anterior malar bone, and posterior parietal eminence. Two objects were to be secured, rotation and extraction, and these must be simultaneous.

The author concluded that deep transverse arrest of the head was a relatively common complication of labor. The diagnosis was easily made from the position of the fontanelles and sutures. The normal termination of the case could not be awaited in most instances, but forceps should be applied as soon as it was evident that rotation would not occur spontaneously. The location of occiput must be determined before the forceps are applied. The blades of the instrument must be applied in that oblique diameter toward which the occiput lay. Traction and rotation must be simultaneous.

Care of the Perineum During Labor and the Puerperium.—Dr. Effa V. Davis of Chicago read a paper on this subject, based on the study of five hundred and fourteen cases. She reviewed the various methods advocated for preservation of the perineum in labor; spoke of the percentage of ruptures, the elements involved in their production, and then discussed her own methods and results; also repair of the perineum and after-treatment of cases.

The Curette in Puerperal Sepsis.—Dr. Geo. L. Eyster of Rock Island discussed two prime forms of puerperal infection, putrid and septic, in one of which he said the curette was a most efficient means of treatment, while in the other its use was fraught with danger.

The General Practitioner and Surgery.—Dr. W. C. Bowers of Decatur said that the study of medicine for general practice should be broad and thorough. It should be undertaken with nothing less than a high-school education, or its equivalent. Physicians should cultivate shrewdness, discernment and a scientific habit of mind. He thought there was a tendency to stagnate and rust after graduation. Interneship in a hospital was greatly to be desired. If not procurable, then the physician should do post-graduate study nearly every year. He was not sure but this should be compulsory within certain limits. Every man in medicine was expected by the public to do at least minor surgery. If not born surgeons, physicians should be good imitators of good surgeons. Great familiarity with medical and surgical diagnosis and pathology were essential to good work, even in minor surgery. The general practitioner should feel his way carefully into surgery, as mistakes in surgery were usually more grave than in medicine, hence the responsibility was greater. The crudeness of methods in surgery and lack of knowledge of anæsthesia among those in general practice were frequently appalling. Cases were cited in point.

Dacryocystitis.—This was the title of a paper by Dr. E. E. Clark of Danville. This disease and its complications gave the physician more anxiety and annoyance than any other comparatively small affection of the eye. The factors and associate conditions leading to this affection were interesting and deserving of much consideration. As to treatment, chloride of zinc had, so far as the author's experience went, given him gratifying results. Before using this remedy he had never heard its use talked of or written about, but some time after his own favorable experiences he saw a brief abstract of an article by Froelich, who employed the same treatment he had been using, and with gratifying results. The author's first case was one of three years' standing, which he had treated for three months, with no improvement. He concluded to try a 20 per cent. solution of chloride of zinc, about 3 drops, as nearly as he could estimate, injected into the sac. The next day there was a very violent reaction, but the single treatment brought about a complete and absolute restoration of all the functions of the drainage system in a few days. Subsequent cases treated with solutions of less strength had given him results that made him enthusiastic in favor of this treatment. He was inclined to believe that results were to be obtained from cataphoresis and [illegible]. However, his experience in this line had not been sufficiently large to warrant a very positive opinion.

Dr. J. J. Pearson of Rochester in a paper on ophthalmia neonatorum emphasized the importance of the subject, and was inclined to think that there was a lack of understanding of the subject by the general profession. He discussed the usual treatment of this affection.

Nephritic Eye Lesions.—Dr. William O. Nance of Chicago presented a paper with this title, saying that ocular affections dependent on kidney disease were of not infrequent occurrence. Every vascular structure of the eye might be involved. He referred to inflammation of the lids, also chemosis, retinal hemorrhages, paresis of extrinsic muscles, interference with action of ciliary muscle, iritis, cataract, and neuroretinitis nephritica. He said the last named condition was of the greatest importance. He thought unilateral involvement was rare. He discussed the effect on vision, the prognosis of the disease, its diagnostic significance, and ophthalmoscopic appearances.

Congenital Dislocation of Hips.—In this paper, Dr. Edward H. Ochsner of Chicago gave a short review of the history of the treatment of congenital dislocation of hips, with especial reference to the Lorenz functional weight method. The history of a case treated by this method was given in detail. He demonstrated the pelvis, which was obtained three years after reduction, and about one year after complete recovery.

A Plea for the Conservation of the Uterus in Pelvic Hemorrhage.—Dr. O. Beverly Campbell of Chicago read a paper with this title. He condemned the routine practice of removing the uterus for pelvic inflammation as the needless sacrifice of an organ which would recover, at least symptomatically, if properly treated. Hysterectomy should be the exceptional practice in pelvic inflammation, and permissible where the uterus was hopelessly diseased. The advocates of the method were fortified in their position by the pathologic findings in the uteri of women affected with pelvic inflammation. Thus, from a pathologic standpoint, the infected uterus rarely underwent perfect resolution under any system of treatment, therefore, its removal was deemed justifiable. The simple fact as demonstrated pathologically, that an organ once the seat of a septic process might never resume its normal condition, did not argue that it must necessarily be removed, provided it did not affect the health and comfort of its possessor. The fault must not be ascribed to pathology, but to failure to associate living pathology with clinical study and the processes of repair.

The essayist then presented arguments lengthy in favor of the conservation of the uterus.

He deemed it incumbent upon those who practise the radical method of removing the uterus in pelvic inflammation to show just cause for their practice. It must be shown from clinical evidence gathered from every available source that the pathology in the uterus in pelvic inflammation was so extensive that resolution did not occur, and its presence was a menace to the health and comfort of its possessor regardless of palliative measures. It must be shown conclusively that the uterus was devoid of function when the appendages were removed. The mere assertion that the uterus was absolutely a functionless organ when the ovaries had been removed could not be accepted as argument. It should be shown that the results, extending over a period of five years, prove that better results were obtained in every particular where the uterus was removed.

The Limitations of Surgery in Gynecology.—In a paper with this title the author, Dr. O. B. Will of Peoria, made a plea for greater conservatism in gynecological surgery of the relative order, having its basis in considerations of surgical physiology, not alone the immediate but ultimate effect as well upon the conscious health of the individual of any given operative procedure. Ablative surgery was limited in its possibilities only by exhaustion of material, but should be restricted to the removal of abnormal products, and along lines of least resistance. Reparative surgery had its natural limitations in the degree of alteration of structure which created the demand for it. It was along lines of what might be called reconstructive surgery that the most misguided and ill-considered surgical enterprise was shown. It constituted a field of operative procedure in which the changes were constantly being rung without proper regard for either the moral, anatomic, or physiologic principles involved. This was too often illustrated in the mere exchange of one [illegible] evil for another, in nervous and mental [illegible], without any compensating advantage. The third point made was that too much attention was relegated to mechanical states, with corresponding neglect of integral tissue conditions upon which more than upon anything else depended the pathologic transformations. It was contended that as an aid to the restoration of normal conditions, temporary mechanical and positional influences were as valuable as were the extensive operative readjustments, without the subsequent functional disarrangements incident to the latter.

Hemostasis of the Broad Ligament.—Dr. Henry P. Newman of Chicago said that ideal hemostasis should insure (1) Absolute security against hemorrhage, primary and secondary. (2) Protection against septic contamination. (3) The minimum of injury to the parts treated. (4) Absence of foreign bodies from the wound. (5) Objections to the conventional ligature.

The author gave his experience with the angiotribe, its advantages and disadvantages. He exhibited his pressure clamp and described his method. He spoke of the use of reinforcing small catgut ligature on the ovarian and uterine artery. He insisted upon the manner of placing this ligature as securing exceptional results. The claims for the combined method were (a) complete and permanent hemostasis, with no possibility of slipping of the ligature. (b) The prevention of hematoma and hematocele. (c) No puckering or massing of broad ligament tissue to draw upon or displace other organs or structures. (d) No strangulated stump tissue remains to slough, granulate and form adhesions. (e) A neat linear stump. (f) The amount of foreign matter left in the wound is reduced to a minimum. (g) Convalescence materially eased and hastened.

Dr. S. C. Stremmel of Macomb read a paper, in which he said that the unsurgical features of vaginal hysterectomy were forceps and silk ligatures, which almost invariably became infected, leaving an open wound between the vagina and peritoneum.

Treatment of Pleural Effusions by Continuous Aspirations.—In a paper on this subject, Dr. Weller Van Hook of Chicago discussed the methods of treating pleural effusions, saying that they were unsatisfactory for a variety of reasons, which he gave. Continuous aspirations by the method of Perthes were not subject to these objections. He described a modification of Perthes' apparatus, and narrated at length his observations and results of this method of treatment.

Tetanus.—Dr. Frank E. Wallace of Monmouth presented a paper in which he reported a case of this disease, followed by recovery. The disease was produced by a germ admitted through a wound, and most generally followed uncleanliness. The incubation period varies—first because of the germ being anaerobic, second, because of individual susceptibility. It was the toxins which produced the symptoms and not the germ. It acted through the nervous system and produced characteristic symptoms. The toxins were only absorbed through the vascular system and not from the intestinal tract. There might not be any local manifestations of infection. Pronounced trismus seems to be the only sign pathognomonic of the disease.

The treatment was based on the following principles:

(1) Removal of the germs at the point of infection; (2) Elimination of toxins; (3) Neutralization of toxins; (4) Control of spasms; (5) Sustaining the patient's strength.

Cleanliness was paramount in dressing surgical cases. Primary injections should consist of at least 500 units of antitoxin serum. The serum acted rather as an immunizing agent than a curative one. Serum was of no avail in tetanus puerperalis. Intracerebral injection of serum was justifiable. The later the onset of the symptoms, the better the chances of recovery. Science should determine the exact amount of antitoxin serum to use in any given case. He said there was a noticeable decrease in the mortality from this disease.

Surgical Tuberculosis.—Dr. T. N. Rafferty of Robinson read a paper with this title, saying that a new and very important department in surgery had been created by the recognition by Lawrence, in 1826, of the inoculability of tuberculosis, and Koch's discovery, in 1882, of the bacillus of tuberculosis. The disease was now recognized in nearly all its forms, and, wherever found, as a surgical disease. This recognition, based on present knowledge of its pathology, had placed its surgical treatment on a firm basis, not yet fully appreciated or positively fixed. He mentioned the varieties of tuberculous disease and the different parts and organs of the body attacked by it, with proper surgical treatment for each. The greater part of the paper was devoted to lung surgery, and the surgical treatment of tuberculous peritonitis.

Remarks upon the Treatment of the More Common Skin Diseases.—Dr. E. A. Fischkin of Chicago presented a table of some three thousand cases of skin affections treated. He discussed the treatment of eczema, acne vulgaris, psoriasis, cutaneous syphilis, impetigo contagiosa, and the dermatomycoses.

Congenital Phimosis.—Dr. C. C. Hunt of Dixon, in a paper on this subject, said that phimosis was a muzzling closure. It was a term usually applied to an elongated prepuce of a male, associated with a congenital preputial orifice. The preputial orifice was normally narrow in the new-born; the mucous membrane of the prepuce and that of the glans normally adherent, so that the foreskin could not be retracted over the glans without undue force. Separation of these normally adherent surfaces took place in early childhood. No surgical interference was necessary so long as these normal conditions prevailed. He thought the religious rite of circumcision was not good surgery. Its imitation on the part of practitioners of to-day was entirely too common, and was reprehensible. No surgery was necessary unless the functions of the organ were impaired, or some otherwise incurable pathological condition existed. The reflex influences of a narrow prepuce had been greatly exaggerated. Surgical interference, when indicated at all, should be the simplest possible. Splitting of the prepuce and uniting the edges of mucous membrane and integument were all that was necessary in the vast majority of cases. The evolution of the organ by the natural processes of growth usually righted conditions, either really or apparently abnormal, if the parts were kept clean and physicians had the patience to await the establishment of adolescence. Removal of the redundant foreskin was not warranted unless the redundancy was extreme, which was an exceedingly rare condition. The indiscriminate amputation of redundant foreskins should be condemned.

The Illegitimate Child.—Dr. H. H. Hart of Chicago, in considering this subject, stated that four parties were to be considered, the child, the mother, the father and the community. The child was an innocent, helpless party, entitled to safe birth, skilled care, proper nutrition and a fair start in life. The mother, as the responsible parent, and also as an errant member of the community, should be so guarded and guided as to restore her to right living, and thus protect the community. The father, as a responsible party, should be made, if possible, to recognize and meet his responsibility. The community was entitled to all possible protection from the social ills which tended to result from illegitimacy. The medical profession were deeply concerned in this matter because they were invariably brought into these cases, and they stood in the position of representatives of the community at large, who were called upon to discharge the most important responsibilities in these cases.

Officers.—The following officers were elected: *President*, Dr. M. L. Harris of Chicago; *Secretary*, Dr. E. W. Weis of Ottawa; *Treasurer*, Dr. E. J. Brown of Decatur; *Editor of the Society's Journal*, Dr. George N. Kreider of Springfield; and *Assistant Secretary*, Dr. James H. Stowell of Chicago. Chicago, Ill., was selected as the place for holding the next annual meeting.

NEW YORK ACADEMY OF MEDICINE.

Section on Surgery.

Stated Meeting, Held May 12, 1902.

John B. Walker, M.D., Chairman.

Nephrectomy and Other Operations in the Same Patient.—Dr. Charles H. Peck presented a woman upon whom he had operated for acute intestinal obstruction. On August 27, 1898, he had done nephrectomy on the right side because of a suppurating hydronephrosis, and, although the operation had been followed by albuminuria, she had recovered. A year later she had become pregnant, and, in spite of the albuminuria, which persisted throughout the pregnancy, made a good recovery. Since then she had become pregnant several times, but had miscarried. On March 20, of the present year, she had been brought into the hospital for curettage for the removal of retained secundines. During this operation it was discovered that there was a rather large hydrosalpinx on the right side and a mass on the other side. On March 31 he had removed the right tube and ovary and the vermiform appendix, the latter being involved in the mass, and also the left tube. The woman did well for the first few days, but, during his absence from the city, her bowels had been neglected, and on his return on the seventh day after the operation, there was fecal vomiting. She had not had a movement of the bowels for several days. On the afternoon of the eighth day, her condition having improved somewhat, the abdomen was again opened, and a complete obstruction of the ileum by a kink and a band was found about eight feet above the ileocæcal valve. The obstruction resulted from adhesions formed after the last operation. This was relieved, and she made an uninterrupted recovery. This was the first case that he had seen of complete obstruction of the bowel from adhesions following a laparotomy in which no drainage had been employed.

Sulphite Laps for Absorbent Dressings.—Dr. Robert T. Morris said that absorbent cotton and absorbent gauze were the materials most generally employed for surgical dressings. Cotton was not very absorbent, but it served to filter out the bacteria and protect the dressings underneath. Both of these substances, were practically pure cellulose. There was another substance which, so far as he knew, had not been used for this purpose. It occurred in the market in bulk in connection with the manufacture of paper under the name of "sulphite laps." It was made by the action of sulphuric acid on wood, and the name was evidently a misnomer. The fibers of this substance are so much closer together that it is much more absorbent than either absorbent cotton or gauze. He had used it in a number of surgical cases, putting a layer of gauze next the wound and the "laps" next to that. He had found it very absorbent. A specimen of each one of the three substances mentioned was placed with its lower end in a basin of water to show the much greater rapidity with which the "laps" absorb this fluid.

Dr. E. M. Foote asked if any tests had been made as to

[illegible]

Wounds, with a Discussion of What Constitutes Rational Treatment.—Dr [illegible] Griffith presented a paper on this subject, [illegible] good wound healing. [illegible] of great importance, but the methods of [illegible]. The [illegible] and it was pointed out that drying [illegible] do far more harm than good. Many surgeons failed to recognize the great advantage of applying to a granulating surface or next a wound narrow strips of gutta-percha tissue laid on like shingles. Moisture should never be applied to an open wound for any length of time, healing under such conditions took place in spite of and not because of [illegible]. Only very light and [illegible] dressings should be used over subcutaneous wounds. The [illegible] favored the use of solutions of hydrogen dioxide, and drying the wound with sterilized gauze prior to [illegible]. The chief opponent to the quick healing of a wound was friction, hence the ancient custom of using [illegible] wounds.

The Skilful Neglect of Wounds.—Dr R. T. Morris said, regarding the use of gutta-percha tissue next to the wound, that this was a very important question. Throughout the world at large gauze and cotton were used next the wound, and yet they were about the worst materials to be chosen. Granulation tissues were apt to be engaged in the cotton or gauze, and on the removal of the dressing the repair of the wound was naturally retarded. This tearing was prevented by the use of gutta-percha tissue next the wound, but it sometimes had the disadvantage of causing the collection of too much serum, with the result that the wound became sodden. To avoid this Lister's protective, which is not quite impervious to moisture, could be used, or silver foil could be substituted. Better than any of these, in his opinion, was the use of the newly introduced substance "Cargile membrane." The skilful neglect of a wound required years of experience.

Dr M. W. Ware said that while there was a great unanimity among surgeons regarding the treatment of operation wounds, this was far from being the case with regard to granulating and accidentally infected wounds. In the latter class one must consider not only the bacteriological [illegible] but the mechanical conditions involved. He had been interested in Dr Morris's demonstration of the comparative rapidity with which water was absorbed by cotton gauze and [illegible], but nothing had been said as to whether the same result was obtained if serum or pus or other fluids were substituted for the water. He agreed with Dr Griffith that the use of dusting powders on wounds should be abandoned, but he condemned the placing of gutta-percha tissue next the wound. If the wound were large and its secretions were sufficient to keep up capillary action and compensate for the drying of the secretions in the dressing, then a dry dressing might be used; on the other hand, if the wound were small and its secretion scanty, a moist dressing should be used to facilitate drainage. Air should have access to the wound for this same reason, and on this account a gauze bandage was preferable to one made of muslin.

A Case of Intraligamentous Ovarian Cyst, Pyosalpinx and Appendicitis.—Dr Joseph Wiener, Jr., reported the following case: [illegible] It was only partly filled with fluid. The lower pole of the cyst was formed by a [illegible]. The two were removed together without rupture. The appendix was found behind the cecum, pointing upward and firmly embedded in a mass of adhesions, from which it was with difficulty extricated and removed. The cyst was made up of two cavities, in one of which the ovary was found.

SECTION ON MEDICINE

Stated Meeting, Held May 20, 1902

JAMES K. CROOK, M.D., CHAIRMAN

The Climate and Health Resorts of Maine.—Dr Guy Hinsdale of [illegible] presented this paper. He said that the climate of Maine was cold and stimulating. The mean summer temperature for the northern third of the State was precisely the same as for the southern two-thirds, i.e. 62.19° F. There had been a notable decrease in the annual number of deaths from pulmonary tuberculosis in the State of Maine in the past ten years, which was attributed to a systematic education of the people as to the nature of this disease and the best methods of controlling it. The mortality from pneumonia was precisely the same in the interior counties as in the maritime counties. Infantile diarrhea was more common in the interior counties. The climate of the coast was especially suitable for those suffering from neurasthenia and insomnia, or those needing recuperation; it was hardly suitable for those suffering from tuberculosis or other chest troubles.

Ocean Climatotherapy in Summer.—Dr H. Holbrook Curtis presented this paper. He said that it was the return ocean currents from the north that made the climate of the Maine coast so cool. The deflection of these currents accounted for the peculiar climatic conditions found at Newport, Block Island and Nantucket. The last-named place possessed an exceedingly small diurnal variation in temperature. The mean temperature of Block Island was 74° F. in summer. A rather long experience with the climate of these islands had impressed him with the fact that many persons experienced as much, if not more, benefit from a sojourn there as from a sea voyage. The enforced rest, regular routine and bracing air explain the beneficial influence of a sea voyage on a certain class of persons, but long sea voyages should be reserved for dipsomaniacs and errant sons. He had seen some remarkable cures of pulmonary tuberculosis at Nassau, W. I., and knew of many patients with weak chests who did very well provided they spent their winters at this place.

Bronchial Asthma and Allied Disorders; Their Summer Treatment.—Dr Beverley Robinson read this paper. He said that asthma was, as a rule, a symptom of various allied affections. An urgent attack could generally be relieved by an injection of morphine and atropine, and the inhalation of nitrate of amyl was also useful. Of the well-known remedies nothing had been found by him superior to iodide of potassium, either with or without the addition of Hoffman's anodyne. The treatment of most importance was the preventive. Whenever possible he sent his patients with catarrhal respiratory affections to Europe for the summer. A spa treatment of three or four weeks was advisable in the long-standing and obstinate cases. If this were not practicable, he strongly favored sending them to sulphur springs in this country, such as Sharon and Richfield. He believed that the air itself in and around sulphur springs was distinctly curative for most catarrhal diseases. Many of these patients also did well in the more or less elevated regions of the Adirondacks. As a general rule, he did not favor sending them to the seashore. Almost all cases of bronchitic asthma which had lasted for some years were apt to have a more or less impaired heart action, and hence they should not be sent to high altitudes. They should also avoid foggy shores. Disturbance of the stomach was a very frequent accompaniment of asthma, but, unfortunately, these digestive derangements were often not apparent, and were only detected by careful study of the individual and of the therapeutic effect of certain remedies. Potatoes and starches in excess should be eliminated from the diet, and tea, coffee and tobacco should be indulged in exceptionally. Arsenic was often exceedingly useful in relieving the dyspnœa. While very exceptionally a brilliant result would follow some special surgical operation, as upon the nasal passages, in the vast majority of cases the ultimate results of such interference were disappointing. The only cases of bronchial asthma which thoroughly and permanently recover are in young persons in whom secondary complications have not developed, and who have exceptionally good and hygienic surroundings.

The Summer Climatic Treatment of Neurasthenia.—Dr. E. D. Fisher took up this topic. He said that it had been his experience that in very high altitudes many of the symptoms of neurasthenia are increased. This was especially noticeable in patients exhibiting cardiac irregularity. It was a common experience to find, among persons in high altitudes and unaccustomed to such localities, a troublesome insomnia. High altitudes, if not extreme, were often beneficial, though the individual constitution and temperament must be considered. Many health resorts, having no specially salubrious climate, had nevertheless won a deservedly high reputation by the establishment of some system of treatment which occupied most of the patient's time, and so largely prevented morbid introspection. In these conditions of exhaustion it was not advisable to join so-called tours; it was far better to go to a moderately cool region, such as the Isle of Wight. Again, Scotland, with its bracing air and out-door life, was a good place. The advantages of the coast of Maine had already been well set forth. In all cases exercise and occupation must necessarily be combined with intelligent medical treatment. There was no climate adapted to neurasthenia *per se.* Extremes of cold and heat should be avoided and also the more crowded and fashionable resorts. Camp life, with plain but sufficient food, was often most beneficial. Many trials must often be made before the best climate is found for the individual case. All exercise should be indulged in in moderation, and the amount of such exercise must be very gradually increased. A permanent cure was only secured by persistent attention to hygienic rules.

Mineral Springs and Resorts.—Dr. James K. Crook spoke briefly on this subject. (See page 1036.)

Dr. Louis Faugères Bishop said that, while the custom was to send pulmonary cases inland, he had seen many of these persons greatly benefited by residence on the strip of sandy land below Point Pleasant, New Jersey.

Dr. Simon Baruch commended the statements made by Dr. Crook, and added that he believed it was more important for the family physician to analyze the mental ingredients of the resident physician at the springs than the waters themselves, for the latter would be of little benefit if not used under the guidance of a physician having the requisite brains and judgment. After all it was not so much the question of climate as a matter of management of the patient in a given climate. There was no specific virtue in any climate, not even for phthisis; the great point was not to send patients to any particular locality there to do as they pleased, but to send them to a suitable place, always to be under appropriate medical supervision while there.

Dr. Rabinovitch referred to the peculiar properties of sea air, especially those dependent upon the presence of iodine.

Dr. S. A. Knopf said that he was positive that a person with pulmonary tuberculosis would do better right here in New York City, especially if living most of the time on the roof, than if sent away to the most ideal climate without proper medical supervision and sanitary surroundings. It was most unfortunate that sea-coast sanatoria had not yet been established in this country for tuberculous children.

NEW YORK ACADEMY OF MEDICINE.

SECTION ON OBSTETRICS AND GYNECOLOGY.

Stated Meeting, Held May 22, 1902.

James N. West, M.D., Chairman.

Complications of Pregnancy.—Dr. Brooks H. Wells opened the postponed discussion on this subject. He said that the chief point that had interested him concerned the best course to pursue when an ovarian tumor was discovered during pregnancy. Statistics showed that only about 2.5 per cent. of those operated upon during pregnancy aborted, while many more mothers were sacrificed if allowed to go on to full term without operative interference.

Dr. G. H. Balleray said that he thoroughly agreed with the position taken by Dr. Wells. He had only operated upon a few such cases during pregnancy, but in every instance with satisfactory result, whereas in a case operated upon after delivery the mother died from a continuation of the sepsis that had demanded the operation. He had had considerable experience with fibromata complicating pregnancy, and did not fear such tumors very much unless they were so situated that it was impossible for delivery to be effected by the natural passages. In a number of cases the fibromata had entirely disappeared after confinement.

Retroversion and Retroflection of the Uterus.—A series of papers was presented on this subject.

Etiology, Pathology and Palliative Treatment.—Dr. J. Riddle Goffe discussed this subject. He first took up the consideration of the forces which maintain the uterus in the normal position. The chief support of the uterus was derived from its ligaments, and especially from the uterosacral ligament, and the uterovesical ligament. This sling of tissue, reaching from the sacrum to the symphysis, was the all-important agent in retaining the uterus in position. While the round ligament had been utilized for retaining the uterus in position after it had been displaced, he believed it normally possessed no such function. Its office was to limit the excursions of the uterus during gestation and throw the intestine behind the uterus. With rare exceptions he did not believe the fundus of the uterus could be displaced except when the uterosacral ligament had been stretched. Among the factors producing such stretching, in the order of their importance, were: (1) Suppurative disease of the appendages; (2) Subinvolution of the ligaments of the uterus after parturition; (3) The presence of a rectocele due to lacerations of the perineum, and (4) Congenital malformation of this ligament, *i. e.* the anterior vaginal wall is so short that the cervix cannot go into the hollow of the sacrum and the fundus tilt forward. Much had been said about the importance of involution of the uterus, but little attention had been given comparatively to the necessity for proper involution of the ligaments as well as the uterus. It should be remembered that the ligaments are [illegible] and are hypertrophied during gestation. Before discharging a patient after confinement, it was the duty of the accoucheur to be sure that involution of the ligaments was complete. The patient could be treated by local treatment with hot glycerin tampons. In the complicated cases there seemed to be no recourse except operation, but in the others much could be accomplished by the use of tampons for weeks [illegible] possible. Pessaries, in his opinion, had their place. A retroversion [illegible] in [illegible] of inflammation and [illegible] cases were affected. [illegible] showed that only about 1 per cent of cured cases was produced by the use of pessaries; on the other hand, the pessary must be comfortable, just like a crutch. The object of a pessary was to take up the slack in the utero-sacral ligaments, and so tilt the fundus to the front. It was often unfavorable to have to use a pessary, and in many cases the persistent use of tampons would make it unnecessary to employ a pessary at all.

Alexander's Operation.—Dr. LEROY BROUN read the paper. He said that this operation was applicable only to that class of displacements in which the uterus was free from adhesions. The broad ligament and the included round ligaments act as guys to the fundus of the uterus, preventing too great motion backward. Especially was this true of the round ligaments, which contain a large amount of muscular tissue. It was, therefore, reasonable to shorten the round ligaments when it was desired to restore to an anterior position a uterus which had been displaced backward. The uterus thus restored was placed in a position to be restrained by the normal forces, i.e., the utero-sacral ligament and intra-abdominal pressure. Where the uterus was held in its backward position by adhesions the best plan was to open the abdomen, separate the adhesions and then follow the plan recently suggested by Dr. J. D. Bissell of the Woman's Hospital, i.e., take out a section of both the round and broad ligaments sufficient to hold the uterus in a forward position. The anatomical results of this operation were excellent. The support of the vaginal column was necessary to keep the uterus at a normal level in the pelvis, even though this organ were in a normal anterior position. For ten years he had been doing Alexander's operation and had followed his patients as carefully as possible. The operation had no death rate other than that attendant upon any other minor operation, and due to outside and unlooked for causes, as for example, tetanus. With this rather large experience he was free to say that no other operation of the kind had given him equally satisfactory results. The uterus had remained forward even after subsequent confinements. He knew of four hernia having occurred in the 300 Alexander's operations, and this accident should be preventable. The relief of the symptoms by this operation was most gratifying alike to patient and surgeon, and the pain in the scars, urged by some as an objection to Alexander's operation, would be entirely avoided if the nerve emerging from the ring with the round ligament were carefully isolated and not included in the ligature. Both pillars of the external ring should be exposed before making any effort to pick up the round ligament. This ligament was easily lacerated by artery forceps and clamps, and, hence, the clamps used to draw out the ligament should have their sharp edges smoothed off with a file. The ligaments are anchored with black silk, two sutures on each side usually being sufficient. The redundant ligament may be cut off or dropped back.

Abdominal Operations for Retroversion and Retroflexion.—Dr. [illegible] H. WRIGHT read this paper. He said that ventral fixation had been proved inapplicable to cases in which pregnancy was likely to occur. Dr. Howard A. Kelly had devised the operation of ventral suspension, and when it had been very generally performed, the relief afforded had not always been permanent, and there had been occasional interference with pregnancy and labor. In June, [illegible], Dr. W. Gill Wylie had devised the operation of intra-abdominal shortening of the round ligaments. His own experience had taught him to lay down the following rules with regard to these operations: (1) Intra-abdominal shortening of the round ligaments should be done in cases in which it was necessary to open the abdomen for the treatment of complicating conditions and in cases of persistent retroflexion in which the derangement recurred with [illegible] and could not be corrected by simpler measures. (2) Ventral suspension should be done in old women in whom there was no risk of subsequent pregnancy and, in the operator's judgment, when the uterus was large and heavy; and (3) Intra-abdominal shortening of the round ligaments should be the operation of choice in young women in whom there was a probability of future conception. These operations should be supplemented by operations for the repair of a lacerated cervix and injuries to the pelvic floor. In cases of subinvolution following abortion and labor he found that the use of boroglyceride tampons or pessaries would effect a cure in a considerable number of cases provided lacerations of the cervix and perineum had been repaired. A number of his patients, after Alexander's operation, had gone through subsequent pregnancies without any difficulty, and the operation had relieved them of their discomfort. His experience with the vaginal operation had been quite limited.

Vaginal Operations for These Conditions.—Dr. H. N. VINEBERG presented a paper on this subject, which was a critical review of fifty-seven cases of vaginal suturing of the round ligaments. He said that he had been the first in this country to perform vaginal fixation. In patients still in the child-bearing period he resorted to vaginal suturing of the round ligaments, an operation which he had devised early in 1896. In May, 1900, he had reported upon his first fifty cases. In forty-seven of these the operation had resulted in an anatomical success and there had been four pregnancies terminating normally at full term. Some of the cases had now been under observation for six years. There had been no mortality in the fifty-seven consecutive cases, and in only three of the first series had convalescence been disturbed by any complications. In every case the peritoneal cavity had been entered and the adnexa brought into view for inspection; moreover, in 70 per cent. of the cases certain plastic operations had been done in addition. There had been two relapses in fifty-five cases. Experience had taught him the advisability of using at least two sutures on each round ligament. He could safely say that there was little likelihood of dystocia following the operation he had devised. There was no occasion to make a raw surface on the uterus.

A New Operation.—Dr. J. D. BISSELL said he could accept most of the views expressed this evening regarding the causes of retroversion, but he had not been pleased with the methods devised for its relief. Alexander's operation was excellent when done under the conditions laid down by its originator, but it was limited in its application. His own operation produced a shortening of both the round and the broad ligaments. The technique involved opening the abdomen, breaking up existing adhesions and the passing of a suture near the fundus of the uterus and another near the brim of the pelvis. These sutures partially controlled the hemorrhage, but their chief function was to prevent a slipping back of the ligament into the pelvis. The next step was to resect the round ligament, cutting out, if thought best, a V-shaped piece. The ends of the divided broad ligament were then brought into apposition by suturing the divided broad ligament transversely. The technique of the operation was demonstrated by Dr. Bissell on a model. Of the twenty cases operated upon in this manner the result had been satisfactory in all with the exception of one case of congenital retroversion, and here the relief came slowly and was only partial.

Dr. A. Brothers said that he had tried all of the various operations recommended and had found a certain field for each of them. He had been satisfied with the result of Dr. Vineberg's operation in a number of cases, while in others it had seemed to him to be a very difficult operation. At the present time the Alexander's operation was his operation of choice, because he considered it one of the minor surgical procedures for the treatment of retroversions of the uterus. One of its great advantages was that it did not invade the peritoneal cavity, and, despite modern advances in surgery, he felt that the opening of the peritoneal cavity should be avoided when not necessary. The difficulty of learning the technique of the Alexander operation seemed to him to be the chief reason for so many other operations having been devised to take its place.

Dr. S. W. Bandler thought too much stress had been laid upon the uterosacral ligament as an etiological factor. The uterus was simply imbedded in connective tissue, and all of the uterine ligaments were simply connective tissue containing some muscle fibers. The ligamentum lata was one of the most important structures in keeping the uterus at the proper level. In all probability most retroflexions were acquired, and, in general, the symptoms observed were not due to the retroflexion itself, but to the associated descent of the uterus. The levator ani was one of the important structures in keeping the vagina in position, and, hence, laceration of this muscle explained the occurrence of rectocele and cystocele. He believed that a retroflexion *per se* could be treated and the symptoms relieved without resorting to operation. The important indication for an operation was a retroflexion with adhesions. In such cases he preferred the vaginal operation. The method of Dührssen seemed to him admirable and incapable of causing dystocia if properly performed.

Dr. Goffe said that he usually found congenital retroflexion in young women who had not suffered from inflammatory conditions in the pelvis, and who presented a shortening of the anterior vaginal fornix. He was a great believer in vaginal work, and favored shortening of the round ligaments through the vagina. In cases of simple retroflexion of the uterus he did not think one was justified in doing a laparotomy or making unnecessary scars on the surface of the body. According to his experience, the great majority of cases, say, 75 per cent., of retroflexion or retroversion of the uterus presenting symptoms were complicated by adhesions, so that in only about 25 per cent. of the cases would Alexander's operation be indicated at all. He had just been told by a member of the staff of the City Hospital that in the past month there had been four autopsies on cases of ventral suspension, and in each instance the adhesions to the abdominal were so long that the uterus had again become displaced into the hollow of the sacrum. His own method of shortening the round ligaments, through the vaginal fornix was by the Wylie-Mann procedure. This operation he considered a minor one, and he had done it 130 times without any complicating peritonitis.

Dr. Broun said that it should be rare for Alexander's operation to be followed by suppuration. This operation seemed to him ideal and beautiful. The frequency of hernia following it depended very largely upon the operator; it occurred so infrequently that one should not expect it. The vaginal operation had not appealed to him, and hence he had not done it. Although for about three years the vaginal route had been employed almost exclusively by Dr. Cleveland and himself at the Woman's Hospital, they had both gradually and almost unconsciously drifted away from this method, and he was positive that the work done now was better than that done during the period mentioned. The same gradual abandonment of the vaginal route had been noted among the other surgeons on the hospital staff. He felt sure this had been brought about solely by an effort towards greater conservatism.

Dr. Wells expressed the opinion that chronic constipation was an important factor in the development of retro-displacements. He had watched the work of the advocates of vaginal operations, and was convinced that it would not become *the* operation of the future.

Dr. Vineberg said that he did not wish to be understood as advocating the vaginal operation to the exclusion of other methods; on the contrary, he favored a careful selection of the operation best fitted to the individual case. Where there were extensive adhesions of the adnexa he would not think of doing the vaginal operation. A careful examination should enable one to decide before beginning the operation what cases could be successfully completed by the vaginal route. The one weak feature of these vaginal operations was the danger of encountering serious hemorrhage. Any method by which the uterus was attached to the abdominal wall was likely to be followed by such firm union as to lead to serious trouble in a subsequent pregnancy. He wished to congratulate Dr. Bissell on his very ingenious operation; nevertheless, he felt that it was a dangerous thing to open the broad ligament.

NEW YORK COUNTY MEDICAL ASSOCIATION.

Stated Meeting, Held May 19, 1902.

Frederick Holme Wiggin, M.D., Chairman pro tem.

A Three Months' Ectopic Gestation and a Hydrosalpinx.—Dr. A. B. Tucker presented these specimens, removed by operation from a woman of twenty-two, married eight months. There was a history of irregular uterine hemorrhage from March until coming under observation on May 10. Six weeks prior to this date she had been suddenly seized with violent abdominal pain, and had almost collapsed. On rising from bed, about one week later, the attack of abdominal pain had recurred, and since then she had suffered almost constantly. When seen by Dr. Tucker on May 10 she was recovering from an attack of collapse; the abdomen was distended and very tender; the pulse was 140 and the temperature 99°F. A diagnosis of ectopic pregnancy was made, and she was sent to hospital, where Dr. George Tucker Harrison saw her and concurred in the diagnosis. She was stimulated for a few days, and then, on May 15, laparotomy was performed by Dr. Tucker. A mass was found filling the entire left side of the pelvis. Through a mass of adhesions he delivered a three-months' fœtus, the umbilical cord, placenta and left ovary; also the right tube, which was the seat of a hydrosalpinx. The abdomen was partially filled with blood clots, and there was every evidence of a recent peritonitis. As considerable oozing of blood followed the separation of the adhesions, the pelvis was packed with iodoform gauze for seventy hours. The patient was recovering satisfactorily.

Dr. George Tucker Harrison said that the adhesions had walled in the hemorrhage and had prevented the woman from bleeding to death. The general teaching at the present time was that rupture of the gestation sac was the cause of the hæmatocele, but while it was true in the present instance it was not ordinarily so. In the vast majority of cases hæmatocele was due to an incomplete tubal abortion with hemorrhage.

The Therapeutic Use of Suprarenal Extract.—Dr. William H. Bates presented an introductory paper on this subject. He said that some years ago, while experimenting with a number of organic extracts he had tried an extract made by himself from the suprarenal gland. The [illegible] however were so remarkable that he had at once begun a special study of its action.

Preparation of the Extract.—The best method of preparing the suprarenal extract was as follows: The fresh suprarenals are minced and washed with distilled water which had been boiling for one hour to drive off the air held in solution. [illegible] parts of the glands are then mixed with twenty parts of boiling water, and the mixture is boiled for fifteen minutes, filtered immediately and the filtrate allowed to stand for two hours at [illegible] F. It is then decanted and filtered into two-drachm bottles. These bottles are loosely corked and heated in a sterilizer at 212° F. for one hour. They are then removed from the sterilizer and kept at 70° F. for twenty-four hours, when they are again sterilized for one hour at 212° F. before being tightly corked. This sterilized solution keeps for many months, although it will spoil within two or three hours after the removal of the cork. The addition of such substances as chloretone, carbolic acid, boric acid and resorcin does not prevent the growth of bacteria, and he had seen infection of the eye follow the use of such solutions. Moreover the action of the extract was impaired by the addition of these preservatives. Dr. R. H. Cunningham had first pointed out that the powdered suprarenal gland contains active poisons which are formed during the process of desiccating the gland. This powder, like the alkaloid, is hygroscopic, and hence, is apt to spoil. The preparation of tablets of suprarenal also tends to impair the strength of the extract by reason of the moisture used in the manufacture of the tablets. The hypodermic use of suprarenal extract was not necessary. If instilled into the mouth of an unconscious patient, as in a case of collapse under anæsthesia, it would quickly stimulate the heart.

In the Treatment of Diseases of the Heart and Lungs.—Dr. Samuel Floersheim read this paper. He said that his first paper on this subject had been published in 1900, and his experience in this field embraced about 500 cases. He recommended that the dry powdered extract be given by the mouth in doses of three grains, with instructions that it be chewed and swallowed without water. It should be dispensed *dry* in capsules, and the patient should chew these capsules. According to his experience, this extract acted directly on the heart muscle, and not through the nervous system. This remedy was indicated in all forms of heart disease in which the pulse was weak, soft and rapid. In almost every case a marked beneficial effect was noted within five minutes, and it usually lasted for a number of hours. Its characteristic stimulating effect was noted even near the fatal termination of cases of organic heart disease, and after strychnine and other well-known heart tonics had failed. In those cases of organic heart disease in which there was full compensation the administration of the remedy did no harm, but was not followed by any appreciable effect. The remedy was exceedingly safe in its action, and was the most powerful heart stimulant known to him. In mitral stenosis it had no effect on the murmur, although the beneficial action on the heart was marked. In aortic regurgitation the murmur often became more clearly defined and more localized. In aortic stenosis, with failing action of the heart, the murmur was sometimes diminished in intensity. Where there were several murmurs so that they were confused with the heart sounds, the administration of the suprarenal extract often brought these murmurs out more clearly. In predominant hypertrophy, with a full, regular and strong pulse, the extract apparently had no effect. Dr. Floersheim said that he had been the first to publish an account of the use of the suprarenal extract in diseases of the lower air passages. He had found it exceedingly useful in many cases of acute bronchitis, but its action was only temporary in chronic bronchitis. Cases of spasmodic asthma due to nervous causes were not benefited. In forty-eight cases of hæmoptysis in which he had used it benefit had been noted. The extract had succeeded in controlling hemorrhage from the lungs when most other remedies had failed. He had used it in twenty-six cases of acute pulmonary tuberculosis. It had no effect, of course, on the tuberculous process, but was administered for its action on hæmoptysis and on the expectoration.

In the Treatment of Diseases of the Nose and Throat.—Dr. Emil Mayer read this paper. He said that it was an exceedingly valuable remedy in operations on the nasal mucous membrane because of its strong ischæmic effect. The contraction of the arterioles of the nasal mucous membrane often lasted for hours, and hence its value in inflammations of the mucous membrane. A few individuals presented an idiosyncrasy, and were made very much worse by its use, and, unfortunately, no one could tell of the existence of such a peculiarity before trying the remedy. Perhaps the greatest value of the extract was in acute inflammatory conditions, and if it had no other use whatever, it must be conceded to be a most useful and wonderful remedy. In the various forms of rhinitis occurring reflexly, as for example, vasomotor rhinitis, it exerted an immediate palliative effect. Many sufferers from hay fever had been very decidedly benefited by its use, but it should be borne in mind that there was nothing curative about its action. It made the sufferer much more comfortable and enabled the rhinologist to reach parts otherwise practically inaccessible. The extract was also useful in operations on spurs of the septum, angiomata, nasal polypi, etc. Some claimed that much more hemorrhage was seen after its use than formerly, but on this point opinion was divided. His own experience was that there was more bleeding subsequently to its use than without it, and hence he used it sparingly and in every instance packed the operated side. The packing was removed in twenty-four hours, and the nose cleansed with peroxide of hydrogen, the suprarenal extract not being subsequently employed. For epistaxis it was oftentimes of great value in that it cleared the field and allowed of appropriate treatment. For operations, such as for adenoids and the removal of tonsils, its use was, in his opinion, absolutely contraindicated. Here, as in the nose, it was well to bear in mind that any hemorrhage that might co-exist with the operation was controllable by the surgeon, whereas a secondary hemorrhage might occur when no assistance was at hand, and consequently a preventable issue might occur. In œdema of the glottis the suprarenal extract was quite useful.

In the Treatment of Diseases of the Eye.—Dr. Wilbur B. Marple discussed this subject. He said that the action of the suprarenal extract in relieving inflammatory redness of the eye was certainly little short of magical, and it delighted the patient, but so also would the patient be pleased by the use of morphine for the relief of pain. We should ask ourselves seriously whether or not suprarenal extract was curative in the long list of diseases for which it had been recommended. His own experience led him to assert that it was not curative. Two cases of conjunctivitis were reported in which, contrary to his instructions, adrenalin had been used for many weeks. Both patients found it necessary to increase the frequency of the instillations after a short time, and finally to increase the strength of the solution, and instead of the drug being curative, it had distinctly aggravated the local condition. There could be no question that adrenalin would secure a bloodless operation, but he was far from being convinced that this use of the extract was desirable, although, undoubtedly, exceedingly convenient. There was certainly an increased possibility of infection, and hence he would not think of using it in an operation in which the globe was opened, and there was reason for believing that the use of this remedy lowered the resistance of the tissues and interfered with healing. For slight operations on the eyelids the extract could be used apparently without harm and enabled the operator to dismiss his patients from the office more quickly. A remarkable case was referred to, in which an epitheliomatous growth on the inner edge of the eyelid, which had existed for a number of years, began to diminish in size coincidently with the employment of adrenalin solution as a placebo. After having used this solution for a number of months, it was found that the growth had entirely disappeared and the cosmetic result was far better than could have been secured with the knife. The action of adrenalin in this case was explained by Dr. Marple on the theory that it destroyed the blood supply of the epitheliomatous mass. The patient was exceedingly susceptible to the action of adrenalin, because when a pledget of cotton moistened with this solution was laid upon this lady's cheek the skin became white underneath the cotton.

In Obstetrics and Gynecology.—Dr. George Tucker Harrison read this paper. He said that he had first used it in a case of chronic hyperplastic endometritis associated with a severe and obstinate metrorrhagia. After curettage and packing the persistence of the hemorrhage led him to prescribe suprarenal extract, five grains three times a day in capsules, and the result was most gratifying. He had also found this remedy useful in cases of uterine myomata. Attention was called to the fact that the administration of this extract gave rise to painful uterine contractions. The coincident tonic action upon the heart was exceedingly useful in many cases of uterine hemorrhage. No doubt radical operation was the better method of treatment, but patients in private practice would not always consent to operation, and the extract proved to be a potent remedy in cases of uterine myomata. Its harmlessness was in striking contrast with ergot in similar cases.

In Diseases of the Genitourinary Tract.—Dr. Edward L. Keyes, Jr., was the author of this paper. He said that so far his experience had convinced him that suprarenal extract had a restricted sphere of usefulness in genitourinary surgery. Meatotomy often gave rise to troublesome hemorrhage, and this could be almost entirely prevented by the use of suprarenal extract. His method of using it was by washing out the urethra with a weak bichloride solution, then inserting a half-grain tablet of cocaine, and after it had dissolved in the remaining drops of the bichloride solution, placing one grain of the powdered suprarenal on the same spot. This would quickly cause a marked blanching of the parts. After the operation he found it desirable to apply glutol, a compound of formaldehyde and gelatin, to insure against subsequent hemorrhage. For moderate urethral hemorrhage the injection of a 5 per cent. solution of suprarenal extract or a 1 to 2,000 solution of adrenalin was admirable. For severe bleeding bandaging of the penis to a retained catheter was still the proper treatment. In some cases suprarenal extract was useful in assisting cystopic examination. In cases of severe vesical hemorrhage he had not found suprarenal extract superior to alum or other astringents. It had been found a useful means of distinguishing between renal and vesical hemorrhage.

Dr. W. Freudenthal spoke of a case of serious tonsillar hemorrhage following incision, in which, after all the usual applications had failed to check the hemorrhage, it was quickly controlled by one insufflation of the powdered extract. Notwithstanding what had been said about the powerful stimulation of the heart by suprarenal extract, his experience pointed to the contrary. In one case of severe asthma, in which the suprarenal extract had been used, there was irregularity of the heart action and a feeling of pain and oppression about the precordium, which ceased on stopping the administration of suprarenal and returned on resuming the use of this agent.

Dr. Francis J. Quinlan said that explorations of the nose, mouth and larynx were greatly facilitated by the use of adrenalin solution. It was particularly useful in some forms of vasomotor rhinitis. When used with cocaine the toxic action of the latter was minimized.

Dr. George B. McAuliffe said that he had thoroughly tried both the suprarenal extract and adrenalin, and he was sure that the best results were obtained from a fresh solution of the suprarenal powder. The powder when dry keeps for an indefinite time, whereas adrenalin has no warning odor of decomposition, and one was not sure, therefore, whether or not it was in proper condition for use. He had repeatedly found patients developing toxic effects of cocaine immediately after the application of the suprarenal extract.

When packing pledgets moistened with suprarenal extract into one nostril he had noticed the ischæmic effect on the opposite side of the nose. He believed that in the eye this remedy had no further value than as a vasomotor constrictor. In checking hemorrhage in the nose, spraying of the suprarenal solution was not sufficient; it should be applied by means of a pledget moistened with the suprarenal solution.

Dr. H. Davison Saril said that he thought iritis could be produced by adrenalin, but that it would be of a mild type. In graduated tenotomies on the eye it should prove useful. For small operations on the conjunctiva it was also of great value. In cataract operations the best method, he thought, was the flap operation, and here free bleeding was desirable, so that suprarenal extract should not be employed. In performing iridectomy in glaucomatous eyes there was apt to be much bleeding which interfered with the operation. Here the application of adrenalin solution would prove useful. While adrenalin was valuable as a hæmostatic it was absolutely valueless as an antiphlogistic.

Dr. D. S. Dougherty said he was sure that suprarenal extract had been the cause of sepsis in some cases, and many patients objected to the odor of this extract. This objection did not apply to the adrenalin, which was also very much more powerful. He had not found it necessary to use pledgets moistened with adrenalin; an application of a 1 to 1,000 solution was sufficient to entirely blanch the parts. It was particularly useful in cases of acute laryngitis marked by great turgidity of the tissues.

Dr. Ernest V. Hubbard said that if, as had been said, suprarenal extract were a stimulant to the heart muscle he would expect it to be applicable to the same class of cases as digitalis.

Dr. Charles G. Am Ende exhibited a solution of adrenalin which was three months old. To keep it well it was only necessary to boil it in a tube closed with a cotton plug.

Dr. William J. Robinson called attention to the fact that in the discussion the expression suprarenal extract had been freely used, whereas it was not the extract but the suprarenal gland that had been used in most instances. The extract occurred in the market in the form of scales, but this preparation was very expensive and, so far as he could learn, had been very little used. Mention was made of a very severe and obstinate case of pruritus vulvæ, in which a few applications of suprarenal gave complete relief. To use this remedy as a curative agent in chronic heart disease seemed to him illogical, although he would admit that it might prove of value as a temporary measure.

Dr. Bates said that it had been repeatedly demonstrated by competent physiological chemists that, unlike cocaine, the contraction of the blood vessels produced by suprarenal was not followed by a secondary dilatation.

Dr. Floersheim said that he had administered as much as half an ounce of the suprarenal powder in the course of eight hours without producing any over-stimulation or other ill effect. In this respect there was a vast difference between suprarenal and digitalis. It was not so much a true stimulant of the heart as a muscle food. He had given at lunch as eight grains at one time without [illegible] any [illegible] stimulation.

Dr. E. Mayer said that in the past year and a half he had used [illegible] to the complete exclusion of [illegible]. He had never yet seen any [illegible] of the good effect of suprarenal or of adrenalin from the prolonged administration of these agents, and he had yet to see a single case in which any injurious effect had resulted from the use of either suprarenal or adrenalin.

Dr. W. B. Marple said that he had referred in his paper only to his own experience with suprarenal in diseased conditions of the eye, and he knew that the deleterious effects were by the drugs and [illegible] treatment.

Dr. G. T. Harrison reported a case which he thought proved conclusively the correctness of Dr. [illegible] contention, that the contraction of the blood vessels produced by suprarenal was not followed by secondary dilatation.

Book Reviews.

Handbook for the Hospital Corps of the United States Army and State Military Forces. By Colonel Charles Smart, Assistant Surgeon General, U. S. Army. Third edition, revised and enlarged. New York: William Wood & Co., 1902.

Excellent as have been the previous issues of Colonel Smart's handbook, the present edition is even more admirable, containing within its covers everything which a hospital corps man is expected to know. The present edition of the book has been generally rewritten, and a very valuable and comprehensive section on military nursing has been added. The book treats of the duties of the hospital corps in peace and war, military organization, general hospital service, elementary hygiene and camp sanitation, anatomy and physiology, first aid in medical and surgical emergencies; military nursing, elements of cookery for the sick, etc. The book is a mine of information, which is set down in clear, yet simple language, devoid of technical terms. The work is absolutely essential for the efficient instruction of hospital corps men in the performance of their duties, and should be as widely distributed among the State troops as it is in the regular army. As a household book of reference for use in the care of the sick and the treatment of domestic emergencies, it is very valuable. It is impossible to give too great praise to this book—the best that can be said of it is that it stands without rivals in its field of application and usefulness. The book is attractively bound and printed, admirably illustrated, and its contents is made readily available by a copious index.

Toxicology: the Nature, Effects and Detection of Poisons. By Cassius M. Riley, M.D., Professor of Chemistery and Toxicology in Barnes Medical College, St. Louis, Mo. Published by the author, 1902.

This little book of 120 pages was prepared for the needs of medical students in their study of toxicology. The treatment given the subject is independent and considered rather from the standpoint of the practitioner than in its medico-legal or chemical aspects alone. The substances treated of are grouped under the headings of inorganic and organic poisons, and these are subdivided under gases, solids, and liquids, manufactured organic poisons, organic poisons of vegetable and animal origin, ptomaines, etc. Under each substance discussed is given a brief description of its physical and chemical characteristics, the clinical symptoms following an overdose, the size of the minimum fatal dose, the duration of life after a fatal dose, the appropriate treatment for the poison, the post-mortem appearances after fatal poisoning, the chemical and other methods for determining the presence of the poison.

The arrangement of the book renders its contents very accessible, and it should prove of much value to students and practitioners for purposes of study and reference. The author has done a service to the profession by the preparation of his book, which is written in clear and concise language, and is eminently practical in character. The subject matter is worthy of a better dress than the cheap binding and poor quality of paper in which it appears.

Diseases of Women: a Manual of Gynecology. Designed especially for Students and General Practitioners. By F. H. Davenport, A.B., M.D., Assistant Professor in Gynecology, Harvard Medical School. Fourth Edition, revised and enlarged, with 154 illustrations. Lea Brothers & Co., 1902.

The present edition, the fourth, differs very little in size and contents from its predecessor, and its value to students or practitioners is to be found in the non-surgical portions of the book. We think the book would have been improved by more revising and amplifying. It is safe to say that a large number of the beginners' gynecological cases will be cases of [illegible], yet only one page is given to its consideration. We think a wrong impression is conveyed as to the frequency of gonorrhoeal vaginitis. It is [illegible] but frequent as an acute inflammation, except in children, [illegible]. We do not think patients with [illegible] pelvic inflammation [illegible] of a temperature of 100°.

Why call a variety of vaginitis "follicular" when there are no follicles, lymph or glandular, in the vagina?

The writer's methods are [illegible] rather than [illegible], as shown by the recommendation of wet bichloride gauze as a dressing for a clean abdominal wound, and the [illegible] for the treatment of adherent retroversion. The statement that gonorrhoeal extension from vagina to uterus is "comparatively rare" is at least debatable.

Such unscientific terms as "tumor," "ingrowth" and "cauliflower growth" are used instead of carcinoma and epithelioma. The book is an excellent one for acquainting students with non-operative gynecological treatment.

Books Received.

While the Medical Record *is pleased to receive all new publications which may be sent to it and an acknowledgment will be promptly made of their receipt under this heading, it must be with the distinct understanding that its necessities are such that it cannot be considered under obligation to notice or review any publication received by it which in the judgment of its editor will not be of interest to its readers.*

A Reference Handbook of the Medical Sciences. By Albert H. Buck. Royal Octavo, Vol. IV., 873 pages. Illustrated. William Wood & Company, New York. Price, muslin, $7.00, brown leather, $8.00, Turkey morocco, $9.00.

Principles of Sanitary Science and the Public Health. By W. T. Sedgwick, Ph.D. 8vo. 368 pages. The Macmillan Co., New York City.

The Principles of Bacteriology. By A. C. Abbott, M.D. Sixth edition. 8vo. 641 pages. Illustrated. Lea Brothers & Co., Philadelphia, Pa. Price, cloth, $2.75 net.

A Text-Book of Insanity. By Chas. Mercier. 12mo. 222 pages. Swan, Sonnenschein & Co., Ltd., London. Price, $1.75.

La Fototerapia. By Dott. Antonio Sciascia. 12mo. 128 pages. Illustrated. Societa Editrice Dante Alighieri, Rome, Italy.

Water-Supply (considered principally from a Sanitary Standpoint). By Wm. P. Mason. 8vo. 448 pages. Illustrated. Third edition. John Wiley & Sons, New York. Price, $4.00.

Twenty-third Annual Report of the Births, Deaths, Marriages, and Divorces in the State of Michigan for 1899. By Fred M. Warner. 8vo. 157 pages. Wynkoop Hallenbeck Crawford Co., Lansing, Mich.

Twenty-First Annual Report of the State Board of Health of New York, with Maps, for the Year 1900. 8vo. 579 pages. James B. Lyon, State Printer, Albany.

A Substitute for X-Rays.—Years ago Becquerel found that salts of the rare metal uranium possessed the power of throwing off a feeble and invisible radiance that affected photographic plates, like the *x*-rays.

Mme. Curie, in Paris last year, isolated from the Bohemian mineral pitch-blende two other elements that behave in the same manner, but are far more active. One of them she called "polonium" and the other "radium." The latter is said to be one hundred thousand times as intense as uranium in its photographic effects.

The property of the new metal is apparently of great practical value. The results of the *x*-rays, now so useful in surgical diagnosis, can be duplicated by a method much cheaper. Radium seems to suffer no diminution of energy or loss of weight during the process. In addition to producing an impression on the photographic plate, radium produces phosphorescence and discharges electrified bodies. Thus it will be seen that it possesses all the qualities of the Röntgen rays.—*Scientific American*.

Medical Items.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, New York City, for the week ending June 21, 1902:

	Cases.	Deaths.
Measles	363	22
Diphtheria and croup	306	32
Scarlet fever	276	28
Smallpox	59	8
Varicella	52	..
Tuberculosis	241	143
Typhoid fever	50	8
Cerebro-spinal meningitis	..	4

Some Unusual Drug Effects upon the Nervous System.—Arthur W. Dunning says that it is a well established fact that lead introduced into the human organism may produce a multiple neuritis. It is also well known that potassium iodide will promote the elimination of lead from the system, but it may not always be remembered that the effect of the iodide upon the lead palsy may be that of greatly increasing the difficulty by too rapidly unloading the toxic agent from its storehouses in the internal organs, and throwing it into the circulating fluid, thereby directly increasing the intensity of the neuritis. He reports the case of a man whose death he considers due to the administration of the iodide. In regard to digitalis, he reports a case of violent mania developed as the direct result of the use of the drug. In another case, the administration of arsenic in the form of Fowler's solution induced sensory disorders, followed later by motor impairment. A singular feature of the case was the absence of any of the usual acute toxic effects of the drug.—*The St. Paul Medical Journal.*

The Parasites of Cancer.—At the German Congress of Internal Medicine, which took place recently at Wiesbaden, Professor von Leyden (Berlin) said that the increase of cancer in Germany and England had induced a great many observers to study its etiology. He then discussed the various themes of Cohnheim, Hausemann and Ribbert. Cancer, from an anatomical point of view, consisted in a proliferation of epithelial cells, together with a destruction of all the other cells. The exciting cause of this proliferation had not yet been discovered. Various parasites had been credited with possessing this power, but none of these hypotheses had stood the test of further investigation, so that any new discovery in that direction was received with some distrust. Very likely the parasites of cancer lived within the cells. Ribbert had asserted that a parasite living in a cell would destroy it, but would not produce proliferation. This view, however, could be disproved by botanical analogies. There was sometimes in cabbage a growth very similar to cancer and known as "Kohehernie," in which plasmodia had been discovered by Dr. Woronin, a Russian savant. These plasmodia grew within the cells and produced first a proliferation and then a destruction of them. The anmill and the alteration of the urine which occurred in cancer must be taken as symptoms of a general infection. Moreover, cancer had been communicated, experimentally, from one animal to another—of course, of the same species. Professor von Leyden also mentioned a case where by accident a student had drunk a fluid consisting of the gastric juice of a patient suffering from cancer of the stomach, the result being his death from cancer within two years. He then described plasmodia, which were found within the proliferated cells in cancer, especially in fresh specimens, and were very like those discovered by Dr. Woronin; the plasma of the cells appeared as if destroyed by the parasites.

Professor von Leyden recently discovered masses of these corpuscles in capsules which were supposed to be sporangia. Similar masses had also been met with in a case of cancer of the lungs.—*Lancet.*

Blasting in New York.—The decision in a federal court in this city that the proper remedy in the case of a person so prostrated by illness that the noise of blasting on private property next door to his home may hurry him to the grave lies in an appeal to the compassion of the blaster, and not to the courts for an injunction, may be the best of law, but it grates harshly on sympathetic feelings. And what can be thought of the man who will keep on blasting in a private, personal enterprise, when he knows that his brutality may kill the victim on a sick bed?—*New York Tribune.*

Health Reports.—The following cases of smallpox, yellow fever, cholera, and plague have been reported to the Surgeon-General, U. S. Marine Hospital Service, during the week ended June 21, 1902:

Feet, enlargement of, of neurotic origin, 27.
Femur, treatment of fracture of the neck, 1014.
Ferments, effect of certain poisons on inorganic, 910.
Ferrometer, Jolles' clinical, 509.
Fever, difficulties in the diagnosis of certain cases of, 1050; pathology of, 307; recovery after high, 158.
Fibroma, intraligamentous, completely separated from the uterus, 436; of the integument mistaken for rheumatism, 59; treatment of uterine, 29.
Filariasis in St. Kitts, 788.
Filters for the French army, 497.
Filth and disease, 97.
Filtration, sand, in relation to disease, 549.
Fire department, duties of surgeons of the, 50.
Fischer, Louis, general treatment of measles, 573.
Fistula, rectovaginal, 958; operation fo rectovaginal, 895.
Flannelette, dangers of wearing, 373.
Floods, sanitary measures to be adopted after, 591.
Florida State Medical Association, 737.
Fœtus, case of malformed, 906.
Folie du doute, 905.
Food as a cause of health and disease during childhood, 121, 155; legislation regarding pure, 496; nutritive value of, 539; preservatives of, 469, 664, 901, 1009.
Foot-and-mouth disease, intravenous infections in, 480.
Forceps, cervix clamp, 399; lever axis traction, 395; use of the obstetric, in cases of tuberculosis, 149.
Ford, J. Herbert, pathological, therapeutic, and clinical notes on a few cases of malarial infection, 521.
Forest preservation in Massachusetts, 175.
Formaldehyde, penetration power of, 188.
Forwood, William H., new Surgeon-General of the Army, 1004
Foundlings of a great city, 819.
Fourth disease, 629; question of a, 431, 867.
Fractures, complications of, and their management, 519; of the base of the fifth metatarsal bone by indirect violence, 1054; of the radius, treatment of, 633; treatment of compound, 966.
Frank, Louis F., a case of facial hemiatrophy, 13.
Franklin, Milton W., on the penetration of the human body by ordinary actinic light, 609.
Freezing point of body fluids, determination of the, by the Beckmann apparatus, 876.
Frost-bite, treatment of, 158.
Furuncle, abortive treatment of, 907.
Furunculosis, pyonephritis and pyonephrosis following, 908; staphylococcus vaccine in, 589.

G

Galactorrhœa, a case of, 169.
Gall-bladder, diagnosis of diseases of the, from appendicitis, 588; empyema of the, 786; healing of wounds and defects in the, by transplantation of the mesentery, 39; method of preserving specimens of the, 354; removal of the mucous membrane of the, 594; surgery of the, 959.
Gallstones, indications for operative interference in, 612; obstruction of the common duct by, 741; with empyema of the gall-bladder, 169.
Gangrene, carbolic-acid, 532; presenile or angiosclerotic, precipitated by influenza, 329.
Gastric neurasthenia, treatment of, 188.
Gastritis, dietetic treatment of, 631; phlegmonous, 115; pneumococcal, 673; streptococcal and pneumococcal, 303; symptoms of chronic non-alcoholic, 848.
Gastroenteric hemorrhage in the newborn, suprarenal extract in, 746.
Gastroenteritis, acute, of infants, 1022.
Gastroenterostomy done with the aid of the elastic ligature (McGraw's method), 133; reflex in, 27.
Gastrointestinal diseases, value of modern methods of diagnosis and treatment in, 348.
Gastroptosis, 1018; and gastric motor insufficiency, 184; splashing sound and atony in relation to, 67; the cause of symptoms attributed to nephroptosis, 1050.
Gastrotomy for removal of a watch, 786; successful case of, in an infant, 376.
Gasu-basu, a new local anæsthetic, 341.
Gauze packing, disadvantages of, 355, 450.
Gelatin, effect of digestion of, on its styptic action, 743; hæmostatic properties of, 751, 856; in melæna neonatorum, 186, 1011; in pulmonary hemorrhage, 24; tetanus bacilli in, 471.
Genitourinary patient, examination of, by the general practitioner, 387.
Georgia Journal of Medicine and Surgery, retirement of Dr. W. E. Fitch from the editorial management, 422.
Germany, post-graduate medical study in, 975.
Gestation, ruptured tubal, 837.
Gilbert, J. Allen, mind and body, 607, 741.
Glandular fever, 519.
Glaucoma, prognosis in, 351; relation of, to thrombosis of the retinal veins, 185; resection of the cervical sympathetic ganglia in, 729; sclerotomy in, 826.
Glennan, Arthur H., the study of quarantine in the light of modern progress, 484.
Glossitis, silver nitrate and chronic acid in chronic, 904.
Glycolysis, 152; destruction by the pancreas of a substance inhibiting, 298.
Glycosuria, experimental, 68; from adrenalin, 758; ocular affections associated with, 672; significance of, 714.
Goelet, Augustin H., influence of prolapse of the kidney on the production of pelvic diseases in the female, 1048; prolapse of the kidney, 182.
Goiter, diagnosis and treatment of, 827; exophthalmic, see *exophthalmic goiter;* medical and surgical treatment of, 189.
Gonorrhœa, curability of, in prostitutes, 745; rôle of the prostate gland in, 23.
Gonorrhœal arthritis, treatment of, 835; ophthalmia, 798.
Gorton, Cora D., external speech-physiology, or so-called lip reading, 894.
Gottheil, William S., on the penetration of the human body by ordinary actinic light, 609.
Gout, nature and treatment of, 66; relation of uric acid and xanthin bases to, 742; rheumatic, salt pack in, 415; respiratory conditions depending upon, 760; saturnine, 788; spa treatment of, 629; statistics of, in the United States, 1017.
Gouverneur Hospital, woman interne at, 736.
Graham, Harris, dengue: a study of its mode of propagation and pathology, 204.
Grandin, Egbert H., a clinical report relating to (*a*) hemorrhage persisting notwithstanding curettage, and (*b*) secondary hemorrhage following abdominal section, 571.
Grape juice, action of, on the organism, 1011.
Grass, sleepy, 280.
Graves' disease, see *exopthalmic goiter.*
Gray, Ethan Allen, the influence of suprarenals in pneumonia, 527.
Great Britain, decline in the birth rate in, 701; general medical council of, 17; post-graduate medical study in, 969.
Green, Edgar Moore, report of a case of Addison's disease, 94.
Green groin, operation upon, 1008.
Griffith, Frederic, a case of galactorrhœa, 169; bile burns in anæsthesia, 614; dentists needed in hospitals, 1049; the privileges of the Academy of Medicine and the dues question, 106; the relation of the dispensary to the hospital, 63.
Gunshot wounds of cavities, 958; of the knee-joint by small caliber projectiles, 865.
Gums, marginal ulceration of the, 431.
Gymnasium directors, society of, 104.
Gynecological operations before medical classes, 220.
Gynecology, medical side of, 912; surgical relations of, 915.

H

Hæmatemesis, gelatin in the treatment of, 24, 351; post-operative, 510; saline injections in, 589.
Hæmatoporphyrinuria, 749.
Hæmatosalpinx, bilateral, 436.
Hæmaturia, 672; nephritic, 471; so-called idiopathic, 948.
Hæmoglobinuria in pregnancy, 1010; see also *Blackwater fever.*
Hæmolymph glands, 752; structure and physiological significance of the, 457.
Hæmolysis, 186; by aqueous extract of tumors, 1053; in heterogenous serum, 67.
Hæmophilia, treatment of, with calcium chloride, 829.
Hæmostasis, electrothermic, 958.
Hair, changes in the color of the, 709; sudden blanching of the, 578; trophoneurosis affecting the, 23.
Hairpin, surgical uses of the, 588.
Hamilton, Charles S., post-operative obstruction in a case of sarcoma of the uterus and mesenteric cyst, due to incarceration of the small intestine in a hole in the mesentery, 854.
Hands, disinfection of, by alcohol, 551, 869; enlargement of, of neurotic origin, 27.

Harrisburg (Pa.) Academy of Medicine, officers of the, [illegible]
Hartley, Frank, abdominal [illegible], 843
Harvard Medical School, gifts to, [illegible] 141, 401
Harvey, [illegible]
[illegible]
[illegible]

Kales, John W., seeds in the appendix, 586
Kennedy, James C., are seeds potent factors in the production of disease of the vermiform appendix? 536
Kennelly, A. E., the report on the Morton current, 181
Keratosis, precancerous, probably due to the x-rays, 227
Kernig's phenomenon, 743; in sciatica, 746; unilateral, as a symptom of focal brain disease, 909

Kerrison, Philip D., a case of respiratory tinnitus, 614.

Kerschner, Edward, restoration of, to the U. S. Navy, 539.

Kidney, anchoring of the, 785; conglomerated cystic, 595; decapsulation of the, 472; diagnosis of prolapsed, 75; electricity in disease of the, 149; examination of the function of the, in the diagnosis of surgical kidney and abdominal lesions, 39; floating, 63, 549; floating, as a cause of obstructive jaundice and hepatic colic, 431; functional diagnosis of diseases of the, 508; malignant disease of the, in children, 1058; new method of anchoring the, 32; paranephritic blood-cyst, 908; pathology of, in pneumonia, 1056; prolapse of the, 182; prolapse of the, in female pelvic diseases, 1016, 1048; symptoms of disease of the, 1013; tuberculosis of the, 792; tuberculous, 308; vicarious elimination following removal of, the, 538.

King Edward, ailment of, 1041; present condition of, 1042.

Knapp, Mark I., floating kidney, 63; report of five cases of ulcer of the œsophagus diagnosed as pulmonary tuberculosis, 334.

Knee-joint, auscultation of the, 148; effect of osteitis of the, on the growth of the limb, 672; fracture of the semilunar cartilages of the, 674; internal derangement of the, 507, 761, 795; internal injuries of the, 28; old excision of the, 795, 796.

Knopf, A. S., official and private phthisiophobia, 44.

Koplik's sign in measles, 120, 170.

L

Labia minora, hypertrophy of the, 437.

Labor, abandonment of digital examination of the vagina in, 227; deflected presentation in, 962; management of normal, 395.

Lacrymal reflex, importance of the, 866.

Lactation, prolongation of, 1022, prolonged, 828.

Ladinski, Louis J., nephrectomy—a clinical study of four cases, 212.

Laidley, Leonidas H., director of the Louisiana Purchase Exposition, 256.

Langerhans' islands, relation of, to diabetes mellitus, 228.

Language, temporary reminiscence of a long-forgotten, during delirium, 1052.

Laparotomy, closure of suppurating abdominal wounds following, 918; combined transverse and longitudinal incision in median, 1033; needless, 148; prevention of ventral hernia after, 1033.

Laryngitis, tuberculous, 869.

Laryngotracheal fistulæ, contribution to the study of, 279.

Larynx, hemorrhage from papilloma of the, 743; perichondritis of the, in a diabetic subject, 490; prolonged intubation of the, 505; syphilis of the, 187; use of a screen in the treatment of tuberculosis of the, 349.

Lateral chain theory of Ehrlich, 909.

Laurel, mountain, poisonous properties of, 409.

Lavage of the intestine in a child, 352.

Lawyers' trust, 142.

Lazear, Jesse W., fort named after, 382; pension for the widow of, 338.

Lead colic, atropine in, 829; poisoning, pathology of chronic, 868.

Lederer, William J., asepsis in dental surgey, 611.

Legislation, recent medical, in New York State, 678.

Lemann, Isaac Ivan, the differential diagnosis of typhoid and malarial fevers, with especial reference to the occurrence of both diseases in the same patient, with report of cases, 1029.

Lepers, segregation of, in Guam, 821.

Leprosy, congenital symmetrical keratoderma resembling, 228; fish theory of 780, 1004; 828; in the United States, 579; legislation aiming to repress, 176; new treatment of, 381; pathological histology of, 80; spontaneous cure of, 601.

Leucocytes, diagnostic and prognostic significance of changes in the, 193.

Leucocytosis, clinical significance of, in pleurisy, 776; in some surgical diseases, 868; prognostic value of, in appendicitis, 588.

Leucorrhœa, yeast treatment of, 26.

Leukæmia, a case of acute, 877; acute myelogenous, 590; chronic lymphatic in an infant, 112; myelogenous, 389; newspaper description of, 200.

Lewis, Denslow, the traumatisms of pregnancy, 561.

Lewis, Robert, Jr., a case of otitic brain abscess and the lessons which it obviously teaches, 412.

Liberty, N. Y., sanitary regulations in, 64, 181.

Licensure, medical, interstate reciprocity in, 58, 61.

Lichen urticatus, post-vaccinal, 674.

Liell, Edward N., report of a case of tubal pregnancy diagnosed one week previous to rupture, verified by operation following rupture—recovery—presentation of rare specimen, 856.

Life, errors in the chronometry of, 857; expectation of, 719; insurance, alcoholism in relation to, 597; insurance examinations, aids in, 713; lowest forms of, 948.

Ligature-passer, an automatic, 319.

Light, electric, see *Electric;* penetration of the body by actinic, 609.

Lightning, loss of life by, 580.

Lilienthal, Howard, suprapubic cystotomy in operations upon the prostate, 88; the treatment of cholelithiasis, 841.

Limburger cheese, prohibition of, in Louisville, 735.

Limping, intermittent, 587, 825; due to obliterating arteritis, 290, 311.

Lip-reading, 894.

Liquid air as a freezing medium in the laboratory, 905.

Lithiasis, pancreatic, 755.

Liver, abscess of the, in the temperate zone, 14; acute yellow atrophy of the, 631; cirrhosis of the, 36, 757; cirrhosis of the, in children, 268; cystic, 24; gunshot wound of the, 194; Hanot's cirrhosis of the, 1047; hypertrophic and atrophci cirrhosis of the, 375; influence of the movements of the diaphragm on the, 908; multilocular echinococcus cyst of the, 313; percussion of the lower border of the, 268; primary cancer of the, 115; professor E. A. Schäfer on the structure of the, 400; prolapsed, use of the gall-bladder as a suspensory ligament of the, 30; pseudocirrhosis of the, 359; pulsating, in mitral and tricuspid insufficiency, 237; resection of two-thirds of the, for angioadenoma, 179; rupture of the, 1058; supernumerary lobe of the, 432; surgery of the, 706; syphilis of the, 1018; tropical abscess of the, 906, 1007; unusual case of abscess of the, 193; use of the gall-bladder to restore a prolapsed, 548.

Lockwood, George Roe, the symptoms of chronic non-alcoholic gastritis, 848.

London, census returns in, 542, 968; foreign medical practitioners in, 479; letters from, 20, 105, 146, 179, 224, 266, 303, 345, 385, 423, 466, 502, 544, 584, 626, 668, 705, 740, 784, 823, 864, 903. 1006, 1047; water supply of, 418.

Longevity, bearing of skin diseases upon, 415; in modern times; 662; vocation in relation to, 577.

Long Island College Hospital Alumni Association, 737.

Loomis Laboratory not subject to the New York University, 177.

Lunacy examiners, a triumph for, 022.

Lungs, acute suffocative œdema of the, 150; chronic distention or inflation of the, 111; circulation in the, 550; sarcoma of the, 676; surgery of the, 955; symptoms and treatment of distention of the, 351; thoracic injuries involving the, 869; tooth in the, 629.

Lupus vulgaris, Finsen's light treatmeat of, 579; hydrogen peroxide in the treatment of, 389.

Lupus, solar cautery in, 776.

Lying-in Hospital in New York, appeal of the, 858.

Lymphadenoma, relation of, to tuberculosis, 20; tuberculous, 69.

Lymphangiectasis, 589.

Lymphangiomata, 517.

Lymphatic constitution, 357; sudden death in, 1026.

Lymphocytes, motility of the, 153.

Lymphocytozoon of the pig, 875.

M

MacCormac, Sir William, incidents in the career of, 17.

MacDonald, Carlos F., the trial, execution, autopsy, and mental status of Leon F. Czolgosz, alias Fred Nieman, the assassin of President McKinley, 1.

MacGowan, Granville, cancer of the prostate complicated by general fibroid change of the urethra—urethrotomy—prostatotomy by the Bottini method—subsequent partial enucleation, 692.

McGraw's method of gastroenterostomy, 133.

McKinley, the assassin of President, trial, execution, autopsy, and mental status of the, 1.

Macpherson, J. D., a severe case of diphtheria involving the pharynx, larynx, trachea, bronchi, and probably the œsophagus and stomach, 374.

Malaria, action of quinine on the parasite of, 296; and cancer, 111, 151, 456, 550; a new factor in the etiology of, 432; a phenomenon observed on the tongue in, 628; best method of administering quinine as a preventive of, 271; blood-slides from two cases of pernicious, 118; cardiac form of, 27; convert to the mosquito theory of, 862; creosote in, 510; diagnosis of, in non-malarious countries 1006; duration of incubation of, 271, 592; estivo-autumnal, at West Point, 673; following abdominal operations, 95; hemorrhagic pancreatitis in, 431; infection of, 580; in the Philippines, 140; in Upper Palestine, 261; latent and masked, 249; mosquitos in the propagation of, 204, 541, 862; nephritis in, 23, 963; notes on cases of, 521; origin of, 870; parasites of, 700; poly- 510; skin eruptions in, 506; terminology for the various stages

of the stomach of, 521; typhoid fever with, [illegible]
Malar bone, removal of, for epithelioma of the cheek, 934
Mallet, R. Harry, [illegible], 171
Man, improvement of, 227
Manila, cholera in, 140, 141, 386, 873, 890; military hospital in, 140; sanitary condition in, 831
Manley, Thomas H., successful defence of, in a suit for malpractice, 661
[illegible]
Marcy, [illegible]
Marine-Hospital Service, consolidation of quarantine in the, [illegible], 248; proposed changes in the, 15
Martin, Walter B., [illegible]
Massage, [illegible], 272
Mastoid, [illegible]
[illegible]
Maternity hospital, a new, 115
Maxilla, removal of the superior, 850
Mayer, [illegible], pathology and treatment, 182
Mead, James E., [illegible], 264
Meals, [illegible], 740
Measles, complications and sequelae of, [illegible], 77; Koplik's spots in, 220, 250; [illegible]; treatment of, 574
Meat from diseased animals, 70
Meatus, [illegible], 154; relation of the caliber of the, [illegible], 1051
Meckel's diverticulum, intussusception of, 187; [illegible] of, 187
Mediastinum, tumor of the, 308
Medical journals, [illegible] in Cleveland, 922; [illegible], 817; [illegible], 805; [illegible], 1057; progress, characteristics and tendencies of medical [illegible] in America, 1038; [illegible] German plan proposed for this country, 261; students, [illegible], 660

Pain, significance of, 22; significance of abdominal, 386.
Palmar reflex, 786.
Panacea, a great, 400.
Panama, climate of, 640.
Pancreas, cancer of the, 514; destruction of a substance inhibiting glycolysis by the, 298; hypertrophy of, after detruction of the

[illegible] gland [illegible] primary sarcoma of the, 172; symposium on diseases of the, 194; treatment of acute injuries of the, 150.
Pancreatitis, causes and varieties of chronic interstitial, 466; hemorrhagic, in acute malaria, 411; surgical aspects of, 929.
Paraffin, prosthetic injections of, 110, 172, 671, 771, 848.
Paralysis, etiology of infantile, 997; fourteen cases of spastic spinal in one family, 1051; recoveries from infantile, 1017; treatment of [illegible] forms, 318.
Paratyphoid fever, 185, 741.
Parents, suggestions to, 112.
Paris, American hospital in, 285; letter from, 31, 275, 447, 887.
Parotid gland, malignant tumors of the, 663; hypertrophy of, after disease of the pancreas, 603; tuberculosis of the, 30.
Parotitis, [illegible], 638.
Parsons, Ralph Lyman, melancholia simplex and melancholia transitoria simplex, 416.
Paschal, William V., report of a case of penetrating wound of the abdomen with protrusion of viscera and injury to the stomach—operation—with a later development of renal symptoms—recovery, 136.
Pasteur, Louis, 1044.
Patella, suture of recurrent fracture of the, 710; treatment of fracture of the, 1011.
Paterson (N. J.) Hospital, change in the management of, 392.
Pathological Institute, advisory board of the, 19; last week of the, 64.
Pathological Society of Philadelphia, 178, 342, 382, 464, 543, 665, 738, 751, 863.
Pathology, discoveries in, 331.
Patients' gifts from, declared illegal, 626.
Pedersen, James, intraperitoneal rupture of the bladder, 475.
Pelvic floor, restoration of the, 1017; hemorrhage, plea for the conservation of the uterus in, 1060; inflammation, prevention of after marriage, 304; suppuration, conservative treatment of acute, 388; suppuration, treatment of, 190; surgery, conservatism in, 952; tumors from suprarenal rests, 224.
Pelvis, drainage of suppurative diseases of the female, 1017; drainage of suppurative disease of the male, 1013; tripartition in the study of the female, 505.
Penis, gangrene of the, 794.
Pennsylvania Society for the Prevention of Tuberculosis, 666.
Perforating ulcer of the foot in leprosy, amputation for, 154.
Pericarditis, 393; diagnosis of, 201; obliterative, 469; tuberculous, 427.
Perimeter, modification of Skeel's, 397.
Perineum, prevention of laceration of the, 22.
Peritoneal surfaces, treatment of raw, in abdominal operations, 279.
Peritoneum, gelatinous carcinoma of the, with metastases in the sternum and lung, 65.
Peritonitis, direct introduction of purgatives into the intestine in cases of operation for septic, 110; early, 1052; operative treatment of tuberculous, 305, 956; recovery after operation for diffuse, 307; recurrent pelvic, vaginal hysterectomy for, 75; treatment of acute general, 387; treatment of inoperable septic, 865; treatment of tuberculous, 297, 305, 956; tuberculous, 756, 1020.
Peritonsillar abscess, 608.
Permanganate of potassium, [illegible] possibilities of, 411.
Personal factor in disease, clinical importance of the, 782.
Pest Hospitals for New York City, 624.
Peterson, Frederick, training in private hospitals, 784.
Phagocytic power of the leucocytes, quantitative estimation of the, 151.
Pharyngitis, acute, of the streptococcal type, 111; gangrenous, treatment of, 869.
Pharyngotomy, low lateral, 916.
Philadelphia County Medical Society, 178, 181, 464, 541, 626, 666, 701, 822, 901.
Philadelphia Medical Club, officers of the, 110.
Philadelphia Neurological Society, 19, 176, 339, 625, 748.
Philadelphia Pediatric Society, 138, 144, 464, 666, 822.
Philadelphia water supply, 141.
Philippines, American hospitals in the, 181; cholera in the, 427; health of American troops in the, 98, 664; leper reservation in the, 414; malaria in the, 140; medical appointments in the, 902; plague in the, 143; smallpox in the, 18, 421; surra among the mules in the, 191.
Phillips, R. H., bilious remittent fever, 815.
Phimosis, congenital, 1061.
Phosphorus, influence of, on organic substances in pills, 472.
Phototherapy, present status of, 24.
Phrenic nerve injuries, 431.
Phthisiophobia, official and private, 44, 56, 155; the good of, 182.
Phthisis, see *Pulmonary tuberculosis*.
Physicians, oversupply of, 17.
Physique, dependence of ability upon, 579.
Piffard, Henry G., static wrinkles, 455.
Pigment bacteria, effects of the change of color on, 632.
Ping-pong tenosynovitis, 828.
Pituitary body, treatment of acromegaly with, 226; body, use of the pressor substance of the, 350.
Placenta prævia, treatment of, 64, 916, 1016.
Plague, agglutinating power of the serum in, 216; bacillus of, in butter, 142; bubonic, 905; coagulating power of the blood in, 828; discovery of the bacillus of, in the proboscis of a mosquito, 352; infectivity of, 141; in India, 415, 422; in the Philippines, 143; report of the Indian commission, 578; rôle of the fleas of rats and mice in the transmission of, 431; snake venom in, 616; treatment of, 696.
Plasmotropic toxin formation in the body, 151.
Plethoric, general anæsthesia in the, 672.
Pleurisy, clinical significance of leucocytosis in, 776; prognosis and treatment of suppurative, 1056; with effusion, prognosis of, 753.
Pneumococcal arthritis, 67, 749, 905; sepsis, 1010.
Pneumogalactocele of the breast, 196.
Pneumonia, 726; acute appendicular, in children, 176; creosote in, 161, 197, 280, 324, 483; delirium in, 552; endocarditis complicating, 965; in the light of modern research, 368; latent, 659, 830; nervous complications and sequelæ of, 599; prophylaxis of, 766; relation of angina to, 229; senile, 1055; subcutaneous emphysema complicating, 591; suprarenal extract in, 527; syphilitic, 306; treatment of, 148, 647, 1018.
Pneumothorax, non-tuberculous, 754.
Pneumotyphoid fever, 355.
Poetic talent, heredity of, [illegible].
Poison, deaths by, in Great Britain in 1900, 1044.
[illegible], a substitute for the grave, 1068.
Pope Leo XIII, mode of life of, [illegible].
Population of the United States, [illegible].
Porto Rico, military boards of health and of charities in, 99.
Post-graduate instruction, [illegible]; in Germany and Austria, [illegible]; in Great Britain, [illegible]; in the United States, [illegible].
Poultices in the treatment of superficial abscesses, 148.
Practitioners' Society of New York, 111, 229, 418, 617, 704.
Precipitin test, value of, in albuminoid differentiation, [illegible].
Pregnancy, acute atrophy of the liver during, 488; brain tumors complicating, [illegible]; cardiac lesions and extra-uterine, 292, 922; complications of, 817; [illegible] diseases of the heart in, 711; [illegible] in, [illegible]; extra-uterine, [illegible]; hygiene of, 598; malignant growths complicating, [illegible]; management of critical cases of ruptured extra-uterine, 232; ovariotomy with viable fetus, 437; traumatism of, 106, 561; uterine displacements complicating, 811.
Presbyterian Hospital Alumni Association, 703, 863.
Press, secular, and the medical profession in Great Britain, 224.
Pressor substance of the pituitary body, medicinal uses of the, 350.
Prize, award of the Boylston, to R. L. Randolph, 840; award of the Nobel, 101; for an essay on the effects of morphine, 22; for sanatorium plans, 103; Nathan Hatfield Lewis, 384.
Prince of Wales, a fellow of the Royal Society, 345.
Proctoscope, the pneumatic, 598.
Prognosis, therapeutic value of, 81.
Prostate gland, 548; abscess of the, 836; cancer of the, 692; gonorrheal infection of the, 281; hypertrophy of the, 31, 349; nature of hypertrophy of the, 706; operative treatment of hypertrophy of the, 707; removal of adenomata of the, 1009; rôle of the, in gonorrhœa, 23; suprapubic cystotomy in operations upon the, 88; surgical relief of hypertrophy of the, 789; total removal of the, 31, 348.
Prostatectomy, 790, 1058; forceps for, 549; infrapubic, 1013; median perineal, 348; perineal, 231, 692; technique of, 789.
Prostitution, regulation of, in Cuba, 461.
Proteosuria, 427.
Proteus vulgaris in surgery, 717.
Pruritus vulvæ, etiology and treatment of, 508.
Pryor, John H., report of the committee on sanatoria for consumptives, 130.
Psammoma of the brain, 674.

Sutures, linen thread for, [illegible]; [illegible] wire [illegible] needle, [illegible]
Swimming baths, bacteriology of, 741
[illegible]
Symphysiotomy, [illegible]
Syphilis acquired in a girl of [illegible] years, [illegible]; bacillus of, [illegible]; [illegible] diagnostic value of blood examination in, [illegible]; general medical treatment of, [illegible]; [illegible] for, 7[illegible]; [illegible], [illegible]; [illegible] in congenital, [illegible]; [illegible] after, 615; of the [illegible], [illegible]; [illegible] prenatal, [illegible]; transmission of, from parent to offspring, [illegible]; [illegible] in general practice, [illegible]
Syphilitic growths, [illegible] of [illegible], 66
Syringe, a new aseptic, [illegible]

T

Tabes [illegible] diagnosis of [illegible] temperature curves in, 745; treatment, 3[illegible]
Tachycardia, an interesting phenomenon in, 827; with extreme deafness, 246
Talipes cavus, pathogeny and treatment of, 83[illegible]; equinovarus, treatment of relapsing, 558
Talma's operation in Banti's disease, 746
Teeth, influence of nasal obstruction on the development of the, 708; instruction in the care of the, 640
Telephones in London, 170
Temperance and total abstinence, 777; reform, antiquity of, 59
Tendons, plastic surgery of, 68, 430; silk, 186; transplantation of, 516, 868, 1011; transplantation of, in the treatment of paralytic deformities, 196
Teratoma of the testicle, 704
Testicle, tuberculosis of the, 793; undescended, 428, 507
Tetanilla, 548
Tetanus, 1060; after gelatin injections, 160; bacilli of, in gelatin, 471; following vaccination, 265, 388, 392, 785, 865; recovery from, 535; sodium sulphate in, 25; traumatic, 258
Tetany, case of, in an adult, 844
Therapeutic agents, proper introduction of, to science and commerce, 832; sera, government control of, 624
Therapeutics, advances in, 834

Thermic fever, report cases of, 751.
Thermometer, an aseptic clinical, 319.
Thomson, W. H., carbonate of creosote in pneumonia, 161.
Thoracocentesis, albuminous expectoration following, 632.
Thorax, penetrating sword wound of the, 432.
Thrombosis, unilateral venous, associated with cardiac disease, 291, 310; venous, from fluorine poisoning, 438.
Tinnitus, respiratory, 614.
Tobacco, disinfecting properties of, 861; some effects of, on the tissues of rabbits, 748.
Tongue, congenital cysts of the, 429; double, 474; treatment of cancer of the, 231; treatment of doubtful ulcerating neoplasms of the, 472.
Tonsillar inflammations, 904.
Tonsillitis, follicular, 324; methylene blue in, 225.
Tonsillotomy, hemorrhage following, 595.
Tonsils, are they normal physiological organs? 50; hypertrophy of the, 270; nature and histopathology of the epipharyngeal, 64; pathogenesis of lacunar keratosis of the, 188; pathology and treatment of enlarged, 356; sarcoma of the, 190; abnormal eruption of a mandibular canine, 480.
Tooth-forceps, improvement in, 465.
Toxins, amount of, in the blood of a horse infected with tetanus, 747; mulitiplicity of, from bacteria of one species, 787.
Trachea, foreign body in the, 535; safety-pin extracted from the, 422.
Tracheal injections in bronchial and pulmonary affections, 866.
Trachoma, 798; of the female genital tract, 732.
Transposition of one viscus, 732.
Treatment, plea for specific plans of, other than by single drugs, 451.
Trephining, curative effect of, *per se.* 869.
Trichinosis, frequency of, in the United States, 458.
Trigger-finger, 830.
Tri-State (Iowa, Illinois, and Missouri) Medical Society, 593.
Trocar and cannula, an improved, 358.
Tropics, food in the, 1003; maladies of European children in the, 186.
Tubercle bacilli, absorption of alexins by, 65; implantation of, 506; in the nail dirt of children, 1010; relation of pseudoleukæmia, 587.
Tuberculin, diagnostic value of, 619, 671, 1009; in tuberculosis, 37; R., use of, 506.
Tuberculosis, accidental inoculation of, in children, 390; agglutination reaction of the bacillus of, 471; alcohol in, 509; bacteriology in relation to, 999; bovine and human, 15, 34, 138, 349, 737, 744; cardiac, 109; climate for, 137; climatic treatment of surgical, 111; committee of the Charity Organization Society in relation to, 1045; creosote in, 226; critical review of some recent literature of, 348; diagnosis of, by the *x*-rays, 26, 38; disinfection of apartments in cases of, 68; genitourinary, 793; gift of a sanatorium for the treatment of, in England, 60; heredity of, 415; home treatment of, 299; hospital for, on Blackwell's Island, New York City, 221; human and and bovine, 15, 34, 138, 349, 737, 744; hypodermoclysis in, 347; ichthyol in, 170; in cattle, 623; included bodies in the giant cells of, 510; in Havana, 382, 466; inoculation of, 716; intrapulmonary injections of iodine in, 552; iodine in surgical, 870; laryngeal, 869; laws regarding, in St. Louis, 19; malnutrition of, 188; municipal control of, in Boston, 267; nature of, 271; need of sanatoria for, 73; neuritis of, 197; New York State hospital for the treatment of, 61; official notification of, 590; of the female genital organs, 69; of the liver, 632; of the myocardium, 965; of the parotid gland, 39; of the peritoneum, intestines, and genitourinary organs, surgical treatment of, 456; of the seminal tract, 792; of the skin following inoculation with the bovine bacillus, 513; of the skin, phototherapy, in relation to, 788; of the suprarenal capsule in a cow, 709; of the testicle, 793, 1050; operative treatment of peritoneal, 305, 956; pericardial, 427; peritoneal, 297, 305, 456, 756, 956, 1020; prevention of, 34, 540; primary intestinal, 870; proper management of the lung in, 65; pulmonary, see *Pulmonary tuberculosis;* relation of lymphadenoma to, 20; renal, 792; serum diagnosis of, 630; subcutaneous injection of yolk of egg in, 472; surgical, 1061; the kidneys in, 308; temperature elevation following muscular elevation in, 24; toxin and bacilli of, in the spermatic fluid of tuberculous animals, 510; treatment of articular, 509; treatment of, by spectral analytical blue light, 816; treatment of intestinal, 225; treatment of peritoneal, 297; urea in the treatment of, 16; use of tuberculin in, 37; uterine, 705; verrucosa cutis, 630; vesical, 188.
Tumor, a rare, 872; etiology of, 28; fibrous coccygeal, 308; general pathology of, 350, 389; in tropical countries, 788; mediastinal, 308; of the central nervous system, 241; phantom, 110; treatment of inoperable, 109.
Tuthill, H. R., prophylaxis in pneumonia, 766.
Twins, xiphopagous, 264, 301, 347.
Tympanites, 352.
Typhoid bacillus, morphology of the, 67; new method for the isolation of the, 367.
Typhoid fever, 668; agglutination in, 359; airborne, 351; antiseptic and eliminative treatment of, 137; bacilli in the blood in, 225, 308; bacteriological diagnosis of, 108; death rate and sick rate of, 425; detection of the bacilli in the fæces in, 549; diagnosis of appendicitis from, 107; early diagnosis of, 741; early diagnosis of a relapse in, 112; epidemic of, at the Iowa State Agricultural College, 348; epidemic of, in the backwoods of Maine, 191; etiology of, 550, 671, 776; evaporation bath in, 1051; eye, ear, and throat sequelæ of, 305; grangrene of the skin in, 507; hemorrhagic, 184; in children, 1055; infection by a paracolon bacillus in an infant, 1021; infection by a paracolon bacillus secondary to, 717; inoculation against, 100, 151; 819, 827; in Philadelphia, 221; kidney complications of, 786, malarial infection in, 520, 1029; mastitis in, 528; meningomyelitis during convalescence from, 952; nature of, 268; new diagnostic point in, 550; orrhotherapy of, 21; paratyphoid infection, 515; peculiar symptom in, 706; perforation of the intestine in, 226; peritonitis without, perforation in, 829; polyarticular rheumatism complicating, 787; prevention of, among troops on the march, 899; purulent tenonitis complicating, 149; rectal alimentation in, 746; sudden death in convalescence from, 432; water in the treatment of, 359.
Typhoid toxins, lesions produced in various organs by experimental poisoning with, 552.

U

Ulcerated sore throat, 1009.
Ulcers, rate of growth of epithelium in, 469.
Umbilical cord, compression of the, 186; cord, management of the, 706; hernia, operative treatment of, 1010.
Union of the medical profession of New York State, 189.
University of Pennsylvania, new medical laboratories of the, 344.
Uræmia, acute delirium with, 360.
Urea in the treatment of tuberculosis, 16.
Ureters, double, 514.
Urethra, clinical significance of a chronic discharge from the, 591; perineal section for stricture of the, 348; prolapse of the, in a young girl, 153; recurrent herpes of the, 829; stricture of the female, with enuresis and dilatation of the bladder, ureters, and kidneys, 280.
Urethral fever, bacteria in the blood vessels a cause of, 675.
Uric acid, sources and effects, 468.
Urethrotomy, external, 1013.
Urine, bilirubin crystals in, 315; fibrin-like bodies in the, 25; instrumental relief of retention of, from prostatic enlagement, 696; study of the, without the microscope, 95.
Urticaria acute, 674; of the upper respiratory tract, 428; pyogenic, 358.
Ussery, W. C., circumcision for the relief of acne, 170.
Uterine appendages, treatment of suppuration in the, 549.
Uterus, a new method of bisecting the, 191; Alexander's operation for movable retroversions of the, 286; cancer of the, 435; curettage of the puerperal septic, inexcusable, 183; double fibroid of the, 37; dystocia following ventrofixation of the, 109; faulty growth of the, 304; fibroids of the, strangulated during puerperal involution, 426; fibroma and cancer of the, 112; hæmostasis of the broad ligament, 961, 1060; hemorrhage from the, 571; hemorrhage from the, persisting in spite of curettage, 634; lacerations of the cervix and of the pelvic floor, 912; lactation atrophy of the, 153, 915; œdema of the cervix of the, 1011; operation for cancer, 960; plastic use of the, in cystocele operations, 108; premature senility of the, 907; removal of adnexæ, for recurrent pelvic inflammation, 436; retrodisplacements of the, 913, 1063; retroversion of the, 598; round-ligament ventrosuspension of the, 65; rupture of the, 590; sarcoma of the, postoperative obstruction in a case of, 854; surgical treatment of retroversion of the, 957; surgery of the, 962; treatment of fibroids of the, 29; treatment of inversion of the, 304; tuberculous adnexa of the, 74; ulcerated polypus of the, 1012.

V

Vaccinia, latent, 470.
Vaccination, a packet for, 676; a possible convert to, 301; charged as assault, 949; creed of the Chicago Board of Health, 238;

dangers of the shield after, 64; discussion on, 141, 913; dry points vs. glycerinated virus, 291; [illegible], 31; illustration of the value of, in Liverpool, 870; Jesty's claim to the discovery of, 412; legislation concerning, in New York State, 594; lichen urticatus following, 634; protection afforded by, 174, 220, 228, 269; regulations of the Berlin Board of Health regarding, 453; skin eruptions following, 184; surgical aspects of, 827; susceptibility to, 150; tetanus following, 285, 388, 502, 865; what constitutes successful, 197
Vaccine, governmental control of, 495; of the Board of Health, 176; propagation of, from calf to calf, 816
Vaccinia bullosa in smallpox, 752
Vagina duplex, 212
Vagus reflex, 148
